PHLYCTÆNÆ also denote little ulcerous vesicles, arising sometimes on the adnata, and sometimes on the cornea of the eye, like so many little bladders full of water: they are popularly called *blisters in the eyes*.

They appear like grains of millet; and, when produced by a sharp corroding humour, occasion violent pain: the pustules on the adnata are red; those on the cornea are blackish, if near to the surface; but whiter, if deeper. They are cured by discutients and driers.

PHLYCTIS, more commonly used in the plural, *phlyctides*, from the same root, signifies smaller vesicles, which usually cluster together upon a circular inflamed base, the contained serum being sometimes clear and pellucid, and sometimes milky, whey-like, or pearl-coloured.

PHLYSIS, a term used by the ancients to express an eruption on the skin, from a redundancy of humours.

PHLYSTÆNÆ. See **PHLYCTÆNÆ**.

PHLYZACIUM, *φλυζακιον*, from *φλυα*, or *φλυζε*, *fervere*, *ebullire*, to be hot, or to bubble, a hot and inflamed pustule on the skin. (See Celsus, De Medicinâ, lib. v. cap. 28. § 15.) In attempting to establish a more definite nomenclature for the diseased appearances of the skin, Dr. Willan appropriated the term *phlyzadium* to one of four varieties of pustules, and defined it in these words: "a pustule commonly of a large size, raised on a hard circular base, of a vivid red colour, and succeeded by a thick, hard, dark-coloured scab." See Willan on Dis. of the Skin, p. i; and Bateman's Practical Synopsis of Cutan. Diseases, p. xxi.

PHOBEROS, in Botany, *φοβερὸς*, formidable, in allusion to the thorns.—Loureir. Cochinch. 317.—Class and order, *Icosandria Monogynia*. Nat. Ord. . . .

Gen. Ch. Cal. Perianth inferior, permanent, in ten ovate, concave, spreading segments; five alternate ones twice the size of the others. Cor. none. Stam. Filaments near 100,

capillary, inserted into the base of the calyx, longer than its segments; anthers very small, nearly ovate. Pist. Germen superior, roundish; style thick, the length of the stamens; stigma thickish. Peric. Berry ovate, fleshy, smooth, of one cell. Seeds about four, nearly ovate.

Ell. Ch. Calyx inferior, in ten segments. Corolla none. Berry of one cell, with about four seeds.

1. Ph. *cochinbinensis*. Lour. n. 1.—Whole stem prickly. Flower-stalks terminal.—Native of Cochinchina, where it forms impervious hedges. Stem shrubby, woody, ten feet high, erect, covered with long, straight, awl-shaped, axillary, solitary prickles. Leaves alternate, ovate, flat, hard, smooth, somewhat serrated. Stalks terminal, each bearing many white flowers.

2. Ph. *chinensis*. Lour. n. 2.—Lower branches prickly, barren; upper unarmed, flowering.—Native of China, where hedges are made of it, like the foregoing. Stem shrubby, woody, erect, eight feet high. Branches spreading; the lower ones only armed with long, straight, mostly solitary prickles. Leaves partly scattered, partly opposite, stalked, ovate, entire, flat, smooth. Flowers pale, many together, on lateral stalks, from the upper branches. Berry fleshy, small, ovate, with few seeds in its solitary cell.—Such is Loureiro's account, the only information we have respecting these plants. He cites under the 2d *Oxyacantha javanica*; Rumph. Amboin. auctuar. 39. t. 19. f. 3. This author speaks of the fruit as unwholesome, causing vertigo, and the wounds caused by the thorns are said to be dangerous. The plant serves for hedges in Java. Rumphius mentions a species or variety with longer spines, which makes formidable walking-sticks for those who go abroad by night.

PHOBOS, FEAR, in Mythology, was personified by the Greeks, and represented with the head of a lion. See FEAR.

PHOCA, the Seal, in Zoology, a genus of the class and order Mammalia Feræ. The generic character is as follows: the fore-teeth are acute; the six upper teeth are parallel, the outer ones are larger; the lower six are parallel, distinct, equal, and rather obtuse; the tusks are twice as long, acute, robust, solitary, the upper are remote from the fore-teeth, the lower form the grinders. There are five or six grinders which are narrow and tricuspidate. There are nineteen species, besides varieties. This is a dirty, quarrelsome tribe, easily tamed, and polygamous; the flesh is succulent, tender, and fat; the skin is useful; the animals inhabit and swim under water; they crawl on land with difficulty, because of their retracted fore feet, and united hind feet; they feed on fish and marine productions, and swallow stones to prevent hunger, by distending the stomach.

Species.

URSINA; Urine Seal. The specific character of this is; head with external ears. It inhabits Kamtschatka, New Zealand, and the adjacent islands; swims impetuously in large families; copulates on shore; is fearless, biting at whatever is thrown at it; the old ones live by themselves, and grow very fat; each has a peculiar stone for its bed, which it never deserts; the males fight fiercely for their females and stations; their combat is single and fair, two never fighting against one; when grieved it sheds tears abundantly. This is one of the larger seals, growing to the length of eight feet, and weighing seven or eight hundred pounds. The female is much less. Though they lie by thousands on the shore, each family keeps itself separate from the rest, and is sometimes so numerous as to amount

PHOCA.

amount to above an hundred. Urfine seals are seen from June to September, during which time they breed and educate their young. In September they quit their stations on the islands, and return, some to the Asiatic, and some to the American shore; but are generally confined to a space in those seas between lat. 50° and 56° . They are so tenacious of life, as to live a fortnight after receiving such wounds as would instantly destroy almost any other animal.

LEONINA; Bottle-nosed Seal. The body of this is brown; the head is crested on the fore part. It has two teeth in the lower jaw, a little projecting; the eyes are large; the whiskers white, annulate with red; all the feet are palmate; and there are five toes on each, with nails growing out behind the tip; hind feet stretched back; with a tail between, two inches long. There is a pretty good specimen of this species in the British Museum, which formerly belonged to the Royal Society. It inhabits the seas about New Zealand, the island of Juan Fernandez, and the Falkland islands. During the breeding season they are seen in great numbers attending their young on the shore; they bring two young at a birth: the females are excessively fierce during the time of rearing their young; towards evening both the male and female swim out a little way to sea, the female bearing the young on her back, which it is said the male frequently pushes off, in order to oblige them to essay their swimming powers. On the arrival of these animals on the breeding islands, they are said to be so excessively fat as to resemble skins of oil; the tremulous motion of the blubber being plainly perceivable beneath the skin. A single seal of this species has been known to yield a butt of oil, and to be so full of blood, that what has run out has filled two hogheads. The flesh is eatable.

JUBATA; Maned Seal. The neck of the male is covered with a mane of loose floating hair. It is of a reddish colour; the young more dusky, in the female more vivid; it is larger than the *P. leonina*, being about twenty-five feet long, and sometimes weighing 1600lbs. The animals of this species inhabit the Penguin and Seal islands, near Cape Desire, on the coast of Patagonia, and are found within the Magellanic straits, and on the Falkland islands, but they have not been discovered in any other part of the southern hemisphere, or in any other place nearer than the sea between Kamtschatka and America. They live in families distinct from the Urfine and other seals, though their manners are nearly the same. The males utter a snorting sound, and occasionally roar like bulls; the voice of the females resembles that of calves, and the young bleat like lambs.

VITULINA; Sea Calf. The head of this species is without ears; the neck is smooth; the body is brown. There are three other varieties.

(1) *Botnica*, in which the nose is broader; the claws longer; the colour more obscure.

(2) *Sibirica*; colour silvery. It inhabits the lakes of Baikal and Oron.

(3) *Caspica*; the colour of this is various.

Whiskers undulate; the eyes have a nictitant membrane; the crystalline humour is globular; the tongue is bifid. The legs are so very short as to be scarcely perceptible; and the hinder ones are so placed as to be only of use to the animal in swimming, or but very little to assist it in walking; being situated at the extremity of the body. When these animals collect together in great numbers on the shore, they diffuse a very strong and disagreeable smell, a fact that is noticed by Homer, who represents Menelaus

relating his adventure on the isle of Pharos, where he was constrained to lie for a time among a flock of seals, disguised in the skin of one of these animals. The structure of the seal is so singular, that, as Buffon observes, it was a kind of model on which poets formed their tritons, sirens, and sea-gods, with a human head, the body of a quadruped, and the tail of a fish. The seal is possessed of a considerable degree of intelligence, and may be tamed, so as to become perfectly familiar with those to whose care it is committed; and even to exhibit tricks and gesticulations. The seal is supposed to be a very long lived animal. Like other quadrupeds, they have various inflexions of the voice, according to the passions with which they are inspired. They are said, however, to differ from them in this, that they delight in thunder storms, and at such periods to sit on rocks and contemplate with seeming delight the convulsions of the elements.

MONACHUS; Hooded Seal. Head without ears; there are four fore-teeth in each jaw; the fore feet are undivided; the hind feet without nails. This species has obtained the name of Monachus, or cowed seal, from the looseness or width of the skin behind the neck, which, when the animal is placed on its back, folds like a monk's cowl. It inhabits the Mediterranean, about the coast of Dalmatia, growing to the length of more than eight feet. The head is small, the neck longer than that of the common seal; the orifices of the ears not larger than a pea; the hair is short and rude; the colour is dusky, spotted with ash-colour; the toes on the fore feet have nails; but the hind feet resemble fins, and have no nails. This species is fully and accurately described in the 4th vol. of the Berlin Transactions.

GRENLANDICA; Harp Seal. Head smooth, without ears; body grey; a lunulate black mark on the sides. It inhabits Greenland and Newfoundland; it is highly esteemed on account of the excellence of its skin, and the quantity of oil which it yields.

HISPIDA; Rough Seal. Head smooth without; body pale brown, rough, with bristly hairs. It inhabits Greenland and Labrador, feeds on shrimps and small fish; it often sleeps on the surface of the water; the flesh is red and nauseous; it is only about four feet long. A variety is much larger, and weighs perhaps 500lbs.

CRISTATA; Crested Seal. Head on the fore part crested; body grey. This species is also distinguished by a strong folded skin on the forehead, which it can at pleasure draw over the eyes and nose, to defend them against the stones and sands raised and scattered in stormy weather. Its hair is white, with a thick coat of black woolly hair beneath, which makes the animal appear of a fine grey. It is found only on the southern parts of Greenland and Newfoundland; and in the latter it is called the hooded seal.

* **BARBATA**, or Great Seal. Head smooth, without ears; the body is blackish. This is similar to the common seal, but grows to about the length of twelve feet, it having been shot in the north of Scotland of that size. Even when so young as to be without teeth it is upwards of seven feet long, whereas the common seal is at its full growth when it has arrived at the length of six feet. It is found in the northern seas. The skin, which is thick and very strong, is used by the Greenlanders for thongs for their seal fishery. The young ones, when first brought forth, are quite white.

PUSILLA; Little Seal. Head smooth, with the appearance of ears. It inhabits the Mediterranean sea, Chili, and Juan Fernandez, and is about twenty-eight inches long.

CHILENSIS. Snout and ears longish, toes five on each foot. It inhabits about the coast of Chili.

MUTICA; Long-necked Seal. Body slender, without claws on the fore feet.

AUSTRALIS. Ears short and pointed; the body is cinereous; hairs tipped with dirty-white; nose set with strong, black bristles; the upper fore-teeth are transversely furrowed; the lower longitudinally; tusks with a smaller secondary tooth on each side; grinders conic, with a small process on one side near the base.

TESTUDO; Tortoise Seal. Head resembling a tortoise; neck slender. It is said to inhabit many European shores; the species is, however, but little known.

FASCIATA; Ribbon Seal. Body blackish; neck, side, and haunches with yellow stripes resembling harness. It inhabits the Kurile islands, and is covered with short, fine, glossy, black hair.

LANIGER; Leporine Seal. It has four fore-teeth in each jaw; the upper lip is thick, with long thick whiskers; the fur is soft and uneven; the feet have nails, and its length is about six feet and a half. It inhabits the White sea, Iceland, and the Frozen ocean.

PUNCTATA; Speckled Seal. Body, head, and limbs speckled. It inhabits the seas of Kamtschatka, and the Kurile islands.

MACULATA; Spotted Seal. Body spotted with brown. It inhabits the Kurile seas, and is very scarce.

NIGRA; Black Seal. Hind legs peculiarly formed. It is found on the coasts of the Kurile seas; but the structure of its legs has not been accurately ascertained.

Dr. Parfons derives the generic name *phoca*, from φῶξ, or, according to Dr. Charleton, from βῶξ, signifying a noise or kind of grunting made by these animals. He also reduces to this genus the *manati*, the *foal* or *seal*, and the *walrus* or *morfe*. Phil. Transf. vol. xvii. 109, &c.

PHOCÆA, in *Ancient Geography*, a town of Asia Minor, belonging to the Ionians, situated on the southern coast of the gulf of Cumæ, N. of the mouth of the Hermus. It had two ports. Its inhabitants had a very extensive commerce along the Mediterranean; and they founded several colonies, and among others that of Marseilles.

PHOCÆNA, or **PORPESSE.** See **DELPHINUS.**

PHOCAIS, in *Ancient Geography*, a territory of Asia, towards the mouth of the Caicus, on the coast of Mitylene, according to Thucydides.

PHOCARIA, an island of the Ægean sea, upon the coast of Attica. Pliny.

PHOCARUM INSULA, an island on the coast of Arabia. Strabo.

PHOCAS, in *Biography*, Roman emperor of the East, was a centurion in the army on the Danube at the time of the revolt from the emperor Maurice, A. D. 602, nor is it at all known how he came to be elected emperor; but probably from his becoming a leader in some sedition. On the intelligence of this revolt, the people of Constantinople broke out in an insurrection, and Maurice was obliged to retire into Asia. Phocas soon after entered the capital, and with his wife was crowned by the patriarch. At the public games which he exhibited on the occasion, a tumult arose, in which he was reminded with threats that Maurice was still alive. The death of that unfortunate emperor, with that of his five sons, soon followed. The reign of the infamous Phocas was full of bloodshed and cruelty, so that he has been justly ranked among the most detestable of tyrants. At length he became an object of terror to his own son-in-law, Priscus, who entered into a correspondence with Heraclius, exarch of Africa, for the purpose of ef-

fecting a revolution. Phocas was, by the arts of Priscus, kept ignorant of his danger till it was too late for effectual opposition. Deserted by his guards and domestics, he was seized in his palace, stripped of his imperial robes, and carried to the galley of Heraclius, who had been proclaimed emperor. After suffering a variety of insults and tortures, his head was cut off and his body committed to the flames, A. D. 610, in the eighth year of his reign. Univer. Hist. Gibbon.

PHOCEAS, in *Ancient Geography*, a town of Sicily, in the territory of Leontium. Thucydides.

PHOCENSES, a people of Greece, between Ætolia and the isthmus of Corinth.—Also, a people of Phocæa, and also of Italy, in Etruria. Strabo.

PHOCION, in *Biography*, an Athenian commander, one of the most virtuous characters of antiquity, was of humble descent, but received a liberal education, and imbibed under Plato, and other philosophers, those elevated principles of conduct which governed his whole life. As he wished to serve his country equally in council and the field, he cultivated the talents adapted to both. He first served under Chabrias, a distinguished commander, but of an impetuous temper. Phocion gained his esteem and moderated his violence. He contributed to the naval victory near Naxos, in the year 377 B. C.; and being afterwards sent in a single vessel among the islands to demand their contributions, he conducted himself with so much prudence, that he brought back with him all the ships and money at which they were assessed. In the war with Philip of Macedon he obtained a complete victory, and on this occasion he gave a signal proof both of his wisdom and humanity. Before the battle he freely suffered those to depart who had no inclination to fight, lest their cowardice in action should disconcert the rest; and after the victory he released his prisoners, knowing the danger they would incur if brought to Athens, from the violence of the populace. Phocion, though an able general, was the habitual friend of peace. He was too well apprized of the unstable character of the Athenian democracy, and the talents and resources of Philip, not to be convinced that a protracted war must be fatal to his country; hence he was the constant opposer of those orators, who never ceased to urge the people to hostilities, and to discountenance all proposals for accommodation. The pure patriotism and integrity of Phocion were founded on their only solid basis, contentment with a little. Amidst the highest honours, his mode of living was as simple and frugal as that of any common citizen. He possessed a little farm, and was not ashamed to perform domestic offices with his own hands. He had a wife who was a worthy partner of his virtues, and placed her glory in his reputation. An Ionian lady once making a display before her of all her jewels and other finery, "My ornament," said the matron, "is my good man Phocion, who is now called for the twentieth time to the command of the Athenian armies." When the people of Megara were privately meditating an union with the Athenians, Phocion zealously promoted the measure; and, assembling a body of volunteers, marched thither, and was joyfully received; and having rebuilt its walls, left it in a state of security, as a valuable accession to the strength of Athens. When Philip entered Phocis, with the intention of invading Attica, Phocion not confiding in the alliance with the Bœotians meditated by Demosthenes, was desirous of an accommodation; but he was over-ruled, and the fatal battle of Cheronea proved the justness of his apprehensions. The death of Philip was celebrated with great rejoicings at Athens by Demosthenes and his party, but Phocion discouraged such indecorous triumph, and

and bid them remember that the victors at Cheronea were diminished only by one man. In the same spirit of avoiding new hazards he disapproved of the contemptuous speeches relative to young Alexander, and the attempts to form a confederacy against the Macedonian power. At length, after a long life spent for the advantage of his country, he was for an error in judgment accused of treason. The populace shewed the greatest exasperation against him, and would scarcely suffer him to speak. At length, obtaining an interval from clamour, he cried, "Athenians, I confess the crime charged against me, and submit to the sentence of the law; but what have these innocent men (pointing to some involved in the same punishment) done to deserve death." The cry of the people was, "They are your friends, and that is enough." The decree was then passed adjudging them all to die, and some even proposed a clause for putting Phocion to the torture. The aged patriot, unmoved amidst the lamentations of his friends and fellow sufferers, was led away, even his enemies admiring the serenity of his demeanour. The popular indignation against him denied his body a funeral in his own country, and it was carried by a slave and burnt in the territory of Megara. A matron with her maid attended on the obsequies, and raising an humble monument on the spot, collected his ashes, and deposited them under her own hearth, praying the household gods to protect them till they should be restored to the sepulchre of his ancestors, when the Athenians should have recovered their senses. This event took place; and his countrymen repenting the wrong they had done him, brought home his ashes at the public expence, erected a brass statue to his memory, and punished with death his accusers. This event occurred in the year 318 B. C. Plutarch. Univer. Hist.

PHOCIS, the *Phocide*, in *Ancient Geography*, a country of Græcia propria; which extended from the N.W. or the Doride to the S.E., where it touched Bœotia, and to the W. bordering on the Ozole Locrians, to the S.W. as far as the gulf of Corinth, and to the N.E. where were the Opontian Locrians and the Epicnemidian Locrians. Although it was watered by many streams, it formed from the N.W. to the S.E. an extensive valley, in the middle of which flowed the Cephissus. Its other principal rivers were the Pindus and the Cachalis. The chief mountain was Parnassus, where were Delphi and the Castalian fountain. The most considerable places were Delphi (Castri), Crissa, Anticyra (Aspro-Spiria), and Elatia (Turco-Chono), the most considerable of the towns in the Phocide. The Phocæans, according to Pausanias, derived their name from Phocus of Corinth, or from Phocus the son of Æacus, who came to this country with the Æginetæ, who made themselves masters of it, and gave it the name of the Phocide. Pausanias mentions several military expeditions of the Phocæans, viz. their concurrence in the siege of Troy; their war against the Thessalians, in which they gained great honour; and their participation in what was called the sacred war, in which Philip of Macedon took a part. The Phocæans were ultimately excluded from the council of the Amphictyons.

PHOCLIS, a town of Arachosia, between Axola and Aricara. Ptolemy.

PHOCRA, a mountain of Africa, in Mauritania Tingitana, which, according to Ptolemy, extended from the lesser Atlas to the promontory Byfadium.

PHOCUSSA, or PHACUSSA, an island of the Ægean sea, and one of the Sporades, according to Pliny and Steph. Byz.

PHŒBEUM, a place of the Peloponnesus, in Laconia, in the environs of Sparta. Livy.

PHŒBI PROMONTORIUM, a promontory of Africa, in the Iberian sea, between Jagath and Alyba-Colauna. Ptolemy.

PHŒBIA, a town of Greece, in the Peloponnesus, which, according to Pausanias, belonged to the Sicyonians.

PHŒBUS, in *Mythology*, a name given to Apollo.

PHŒMIUS (*Phamcub*), in *Ancient Geography*, a river of Africa, in the eastern part of Mauritania Cæsariensis.

PHŒNICA, or PHŒNICE, a town of Epirus, in Chaonia, according to Ptolemy, Livy, and Polybius.

PHŒNICA (*Fenck*), a town of Asia, at some distance N.N.W. from Tigranocerta; S. of the lake Thospitis, and besieged and taken by Sapor, king of Persia, as Ammianus Marcellinus reports.

PHŒNICE, PHŒNICIA, a country of Asia, commonly named by the Jews *Canaan*, though some part of it, at least, was known to them by the name of Syrophœnicie. Phœnicie was sometimes extended to all the maritime countries of Syria and Judæa, and Canaan to the Philistines, and even to the Amalekites. On the contrary, these two names, and the rest, were most generally swallowed up by those of Palestine and Syria; or rather Phœnicie, Palestine, and Syria, were promiscuously used for each other, and particularly the two former. Stephanus Byzantinus says, that Phœnicie and Palestine are the same. Syria, in its largest extent, sometimes comprehended Phœnicie and Cœlesyria. The fact is, that the whole coast of the Mediterranean sea from Libanus to Rhincorura, or to mount Casius, in the vicinity of Egypt, before the departure of the Israelites from this last country, was inhabited by people of different origin, viz. the Canaanites, afterwards called Phœnicians, descended from Canaan; and the Philistines, sprung from Mizraim. These people lost part of their possessions by the conquest of Joshua, who put the Israelites in possession of the middle part of this coast, from Jamnia to mount Carmel. But when the Israelites were carried into captivity by Salmanasar, 721 years B. C., the portion of the country which they had occupied returned to its first masters, who reunited it to their ancient dominion. From this time the Phœnicians and Philistines were no united, that they were considered as the same people, and the whole coast was known by the name of Phœnicia. Strabo (l. xvi.) makes Phœnicia to commence, towards the N., at the town of Orthofia to the S.W. of Aradus; but Ptolemy extends it a little farther to the N., and removes it to the river Eleutherus, which falls into the sea, N.E. of Aradus, and at a small distance from it. The greatest part of the coast of Phœnicia was bounded to the E. by the mountains of Libanus, which are covered with snow during the whole winter. This snow has such a refrigerating effect on the air, that the country towards the N. is cold; but to the N. and S. of these mountains, the air is very temperate.

The proper Phœnicie, as far as we can learn from the ancient geographers, lay between the 34th and 36th degrees of north latitude: bounded by Syria on the N. and the E., by Judæa on the S., and by the Mediterranean on the W. Ptolemy, as we have already said, reckons the river Eleutherus the boundary of Phœnicie to the N., but Pliny, Mela, and Stephanus, place it in the island of Aradus, lying N. of that river. On the coast of Phœnicie, and S. of the river Eleutherus, stood the following towns; Simyra, Orthofia, Tripolis, Botrys, Byblus, Palæbyblus, Berytus, Sidon, Sarepta, Tyrus, Palætyrus. Sidon may be properly called the metropolis of Phœnicie. For an account of the principal towns of Phœnicie, see their respective names. In the midland Phœnicie Ptolemy reckons the following towns, viz. Arca, Palæbyblus, Gabala, and Cæ-

farea Panix. This province was considerably extended in the times of Christianity; when being considered as a province of Syria, it included not only Damascus, but Palmyra also.

The soil of this country is good, and produces many articles both of food and clothing; the air is salubrious, and the climate agreeable. The sea on this coast formerly produced a quantity of such fish as yielded great profit to Tyre in particular: such was the murex, with which was dyed the choicest purple; and on the shore was a sand with which the first and best glass was made, as a staple manufacture of this country. Although this country has been long desolate, it exhibits some remains of its ancient splendour, more especially at Tyre, Sidon, Byblos, &c. which see respectively.

The Phœnicians were, without doubt, descendants of the Canaanites: though, in process of time, their blood was intermixed with that of foreigners, from the natural course of their commerce with other countries. Many strange families must have settled among them, who could consequently have no claim to this remote origin, how much soever they have been called Phœnicians, and reckoned of the same descent with the ancient proprietors. Bochart indeed insinuates (vid. Phaleg. lib. iv. cap. 34.) that the Canaanites were ashamed of their name, on account of the malediction denounced on their progenitor, and that they were terrified by the wars, which had been with equal vigour and success waged against them by the Israelites, because they were Canaanites; and that, therefore, to avoid the ignominy of the one and the danger of the other, they abjured their old name and changed it for Phœnicians, Syrians, Syrophœnicians, and Assyrians. Heidegger also conjectures, that they were ashamed of their ancestor Canaan. As to the etymology of their name, learned writers have suggested a variety of conjectures. The mythological historians have traced it to a pretended Phœnix, son of Agenor, or to a Phœnix, said to be the son of Neptune and Libya. Others have derived it from $\phi\omega\mu\acute{\epsilon}$, or the palm-tree, with which Phœnicie is said to have abounded. Scaliger pretends that the name of Phœnician was formed from *Pinkkas*, or *Pinnbas*, meaning a person who inspires confidence, which as he supposes was given to Canaan by the Sidonians. The learned Bochart seems to have approached nearer to truth in his conjecture. According to him, these people had, in ancient times, been called the children of Anak, or "Beni-Anak:" the *beth* being softened, Beni-Anak was changed into "Phenak," in the plural "Phenakim," from which the Greeks formed "Phœnices." We learn from scripture, that the spies sent by Moses found in Hebron and its environs a people called "Anakim," or "Enakim:" and that these Canaanites were distinguished by their stature and strength: of course, the other Canaanites who claimed the honour of descent from them were also denominated "Anakims."

M. l'Abbé Mignot, in his elaborate discussion of this subject, (Mem. Acad. Belles Lettres, tom. xxxiv. &c.) thinks that it is not necessary to recur to the word "Beni;" because the Egyptians always prefix the article *phe* to words, so that instead of "Enakim," they would read "Penakim," or "Phonacim:" and the Greeks becoming acquainted in their first maritime expeditions on the coast of the country with this word, formed from it $\phi\omega\mu\acute{\epsilon}$, and the Latins "Phœnices."

It has been presumed by this ingenious writer, who has taken great pains in tracing the origin of the Phœnicians, that a new colony of Canaanites arrived in this country, which drove the ancient inhabitants towards the N., and in

proof of this opinion he refers to Gen. xii. and xiii. These new Canaanites he supposes to have been the Orientals whom authors have distinguished by the appellation of "Egyptian Shepherds," and who, after having been driven from the country which they had once possessed, returned again to Palestine. Accordingly he supposes these "Shepherds," of whom we shall have occasion to speak in another article, were the progenitors of the Phœnicians. The kings of the Thebaid, and other princes of Egypt, formed a league against them, and carried on a war, which was long and cruel; till at last the king Musphar Muthosis obliged them to withdraw into a canton, which contained 10,000 arouræ or Egyptian acres. The Shepherds fortified this place and encompassed it with walls for the security of their possessions. Thummosis or Thetmosis, at the head of 480,000 men, besieged this place; but despairing of success, he treated with the besieged, and granted them permission to retire, with their whole property, to any place they might choose, without being pursued or disquieted in their march. The Shepherds accordingly quitted Egypt, and pursuing their route through the desert, arrived in Syria, and settled in the country which was afterwards called Judea. This departure of the Shepherds from Egypt is said to have taken place before the arrival of Joseph in that country, *i. e.* in the year 1728 B.C. This fragment of ancient history throws great light, according to the abbé Mignot, on the Egyptian allegories. The synchronism of the arrival of the Phœnicians in Egypt with the reign of Menes, leads us to imagine, that the whole fable of the war of Typhon against Osiris is an allegory, under which is veiled the history of the war of the Phœnicians or Canaanites against the Egyptians. Typhon was the brother of Osiris; and he corresponds to the Canaanites, who were descended from Canaan, the brother of Mizraim, and who might be called the brethren of the Egyptians, according to Eastern usage: but although brethren they were not born in Egypt, which the fable sufficiently indicates, by the different colour which it gives to Typhon, who was red. The Egyptians, compared with the Canaanites, were almost black. According to the fable, the war between Typhon and Osiris was long, and terminated by the retreat of Typhon from Egypt, thus characterising the expulsion of the Shepherds. Typhon retired to Abaris, which was called the city of Typhon; but he was obliged to leave it and to abandon the whole country: and as he never returned, he is thought to have been drowned in the overflow of the waters of the Sirbonite lake: but his death is supposed to have been allegorical; for, according to Plutarch, (De Is. and Osir.) he had two sons, Judæus and Jeralymus; the meaning of which is, that he entered into Syria, and settled in the country of Canaan, since occupied by the Jews, and in which was the city of Jerusalem. According to the abbé Mignot, the commencement of the reign of Salatis, the first Shepherd king, may be fixed to the year 2078 B.C., and their departure to the year 1793, before the same era. The Phœnician Shepherds re-entered the country of Canaan, from which, about three centuries before, they had departed for Egypt, and settled towards the south; and, according to Justin (lib. xviii. c. 3.) they established themselves in the vicinity of the lake of Assyria, *i. e.* the lake Asphaltites; but multiplying there they were under the necessity of extending their borders, and taking possession of the territory of the sea-coast, which the first inhabitants of the country had left vacant; and some of them settled in the neighbourhood of the Jordan. Their arrival in Palestine was the cause which induced some of the ancient

inhabitants to remove towards the north. There they multiplied themselves to such a degree, that the country, which in the time of Jacob was destitute of inhabitants to cultivate the soil, was peopled with a race which terrified the spies of Moses by the magnitude of their cities, and by the number and power of those who inhabited them. The Philistines also are said to have come from Egypt; they were established to the south of the Canaanites, having, in former times, inhabited Pelusium and its territory. The Caphtorim were also of the same race; and these people, together with the Canaanites, constituted the nation, which, in process of time, bore the name of Phœnicians. (See PHILISTINES.) Another French author, viz. M. de la Nauze, maintains (Mem. de Let. t. xxxiv. M. p. 175.) that the Phœnicians, who were also called Erythræans, were descended from Edom or Esau, and that the Jews considered them as brethren. He says also, that Esau was the same with king Erythras, both names signifying red; and that he was one of the first kings of this nation. But the reply of the abbé Mignot comprehends the following propositions, viz. 1. That the principal towns of the country to which the Greeks gave the name of Phœnicia, had for their founders and first inhabitants, the children and descendants of Canaan. 2. That the inhabitants of Tyre and Sidon, whilst they were called Phœnicians by the Greeks, were named Canaanites in the original text of scripture. 3. That the translators of the bible, which, in the time of Ptolemy Philadelphus, had rendered the Pentateuch into Greek, were persuaded that the Phœnicians were Canaanites, as they often express the Hebrew word "Kenani" by those of Φοινικισ and Φοινισσας, or Phœnicians. 4. That the Phœnicians gave themselves the name of Canaanites. 5. That some profane authors, such as Sanchoniathon and Philo of Biblos, his translator, assure us, that Chna, or Canaan, was the father of the Phœnicians: and others have called Phœnicia the land of Canaan.

The Phœnicians were governed by kings, and their territory, small and narrow as it was, included several kingdoms, viz. those of Sidon, Tyre, Aradus, Berytus, and Byblos or Byblus. In this respect they imitated and adhered to the primitive government of their forefathers, who, like the other Canaanites, were subject to many petty princes, to whom they allowed the sovereign dignity, referring to themselves the natural rights and liberties of mankind.

As to their religion, the Phœnicians, being originally Canaanites, were at first worshippers of the true God. In the time of Abraham the worship of the Canaanites was not different from his own. But afterwards they combined with the worship of the supreme Sovereign, whom they acknowledged to be the first cause of all things, that of gods, called by the ancients natural and immortal, that is, the sun, moon, stars, and elements. Thus commenced the idolatry of the Phœnicians. They proceeded to reverence as gods those who had rendered any important service to mankind; they decreed to them divine honours; they appropriated temples to their worship; they adorned columns, on which their names were inscribed, and established solemn feasts in honour of them: and moreover, they gave to these new deities the names of the elements, and of those objects to which they had been accustomed to attribute divinity. The first mortal to whom the Phœnicians paid reverence was *Chryfor*, who had invented the method of founding metals, and applying them to the construction of instruments for facilitating agriculture and fishing; who had first ventured himself on the sea, and who had furnished them with the principles

of divination. The worship of this pretended divinity was established wherever they had colonies; and a similarity has been observed between the *Chryfor* of the Phœnicians and the *Pha* or *Vulcan* of the Egyptians. With this deity they associated another called *Agroneros* or *Agrotes*, in honour of whom they erected a statue and a temple, and whom they held in very high estimation, as having invented, or at least perfected, the art of tillage.

The other gods of the Phœnicians, named by Sanchoniathon, were *Elioua*, called the *υπερος*, or most high, and his wife *Berouth*, and his descendants, who were regarded as the founders of the Phœnician nation. *Elioua* and *Berouth* had four sons, *Ius*, called also *Chronos*, *Bethylus*, *Dagon*, and *Atlas*. The wife of *Chronos* was *Ajlarte*, supposed to be the same divinity with *Derceto* or *Atergates*, worshipped at *Afcalon*. *Cronos* had seven daughters, called *Artemides* and *Titanides*, and two male children, *Pothus* or *Cupidus*, and *Eros* or *Love*. *Cronos* had another wife, called *Rbea*, and a third called *Dioné*. To these chief deities they joined marine divinities, such as *Nereus*, the father of *Pontus*, from whom sprung *Poseidon* or *Neptune*. The *Cabiri*, called also *Dioscuroi*, *Corybantes*, and *Samothraces*, received divine honours. Sanchoniathon mentions another prince contemporary with *Cronos*, called *Adad* or *Ædad*. To these gods we may join *Adonis*, a Phœnician prince, who had reigned over *Libanus*, and the *dii pataici*, or tutelary gods of vessels. The Phœnicians had also *Beelfamen*, signifying lord of honour, and denoting the sun; *Baal-Berith*, or the *Cronos* worshipped at *Berytus*, and several others of the name of *Baal*; *Apollo*, *Melicarthus*, *Melcartus* or *Hercules*. There is reason to believe, that the Phœnician idolatry and superstition were not altogether their own; and that their subjection to the Assyrians, Babylonians, Persians, and Greeks, made great alterations in the whole system of their religion. How far they retained, or lost, a due sense and notion of the true God in this their multifarious idolatry, it is not easy to determine. It is reported of the Egyptians, that, amidst their endless polytheism, they still acknowledged one supreme God; and since the religion of the old Phœnicians was in substance scarcely different from that of the Egyptians, it is very probable that their theory and doctrine agreed together as well as their practice and traditions. *Baal* had his prophets and priests in great number. We read of 450 of them, fed at *Jezebel's* table only. It was their custom to offer burnt-offerings and sacrifices to this god, and to dance about the altar with violent gesticulations; thus working themselves up into a kind of phrensy, and then cutting their bodies with knives and lances, and pretending to prophecy, or rather seeming, as if possessed by some invisible power. This extravagance, in their early days, was accompanied with the barbarous custom of sacrificing persons that were most dear to them to appease their false gods, when they laboured under any public calamities. This inhuman practice is not only charged upon them by the testimony of others, but acknowledged by themselves; and they had it in common with the Egyptians. But it was discontinued here, as well as in Egypt, at an early period. (See *ADONIS*, *ASTARTE*, *BAAL*, and *HERCULES*.) Among other acts of worship performed by the Phœnicians, one of the most universal was that of saluting the statues of their gods, or kissing the hand in saluting them. The prayers which they addressed to their gods were preceded by lustrations, by washing themselves, and changing their garments. They also had songs, which they chanted to the sound of instruments. The Phœnicians also practised various kinds of divinations and enchantments. Herodotus supposes these people to have practised circumcision: but Josephus asserts, that

PHŒNICIA.

that none of the nations included under the vague name of Palestine and Syria, used that rite, except the Jews: that if the Phœnicians anciently had that custom, they afterward neglected it, and at length wholly laid it aside. They abstained from the flesh of swine.

Language and Writing.—Whatever was the origin of the Phœnician language, it is certain that it had no affinity to the other oriental tongues that were used in Arabia, Syria, &c. Their language was a dialect of the Hebrew, the same with that of the ancient Canaanites, and their letters, or characters, were the same or very like to those of the Samaritans. Their alphabet consisted of the same number of letters with the Hebrew alphabet; the forms of their letters were larger; but they were more conformable to those of the more ancient Greek inscriptions. The Phœnician character varied in its figure according to the different cantons in which it was used. The character of Palmyra more nearly resembled the Hebrew; that of Carthage or the Pœni, and that of Sicily or Spain, had a common origin, and bore affinity to that of the Phœnicians. The character, which was common to the Phœnicians, Hebrews, Arabs, &c. was the origin of that of all the nations which lay to the W. of Asia; it passed into Africa by means of the Carthaginians; it was in use in Sicily and Spain before the Romans conquered those countries; Cadmus brought it among the Greeks; it was adopted by the Etruscans; and at length received among all the nations of Europe. Towards the E., it had been for a long time in use in Persia, and it was not improbably the origin, directly or indirectly, of all writing. The Phœnicians, like the Hebrews, Arabs, &c. wrote from right to left; nor had they any vowels in their alphabet, which proves the antiquity of their language, and as some have alleged, that it was the inevitable consequence of hieroglyphical writing.

Learning and Science.—The Sidonians, under which appellation we may comprehend the Phœnicians in general, were of a peculiarly happy genius: arithmetic and astronomy are supposed to have taken their rise among them, or were brought by them to great perfection; from them these excellent sciences spread into Greece, together with their letters. They were addicted from the beginning to philosophical exercises of the mind; inasmuch, that a Sidonian, named Mosechus, taught the doctrine of atoms before the Trojan war; and Abomenus of Tyre is said to have puzzled Solomon by the subtilty of his questions. Phœnicia continued to be one of the seats of learning, and both Tyre and Sidon produced their philosophers in later ages; such were Boethius and Diodatus of Sidon, Antipater of Tyre, and Apollonius of the same place, who gave an account of the writings and disciples of Zeno.

Manufactures and Arts.—The glass of Sidon, the purple of Tyre, and the exceeding fine linen they wove, were the product of their own country, and of their own invention; and for their extraordinary skill in working metals, in hewing timber and stone, and in a word, for their perfect knowledge of what was solid, great, and ornamental in architecture, the reader need only be reminded of the large share they had in erecting and decorating the temple at Jerusalem under their king Hiram. Their fame for taste, design, and ingenious invention was such, that whatever was elegant, great, or pleasing, in apparel, vessels, or toys, was distinguished, by way of excellence, with the epithet of "Sidonian."

Commerce and Navigation.—As merchants they may be said to have engrossed all the commerce of the western world; and as navigators, they were the boldest, the most experienced, and greatest discoverers, of ancient times: indeed they had, for many ages, no rivals. In planting colonies

they exerted themselves so much, that, considering their habitation was little more than the slip of ground that lay between mount Libanus and the sea, it is surprising how they could furnish such supplies of people, and not wholly depopulate their native country. Their vicinity to Syria, which had a very considerable and regular trade with the more eastern regions, induced them to traffic in foreign commodities; for here they found productions of the natural growth of that soil, and many choice and useful commodities brought from the East, which their own small country could not supply: and having probably been shewn the way by the Syrians, who might have navigated the Mediterranean, they turned their whole attention to trade and navigation, and by an uncommon degree of application, soon eclipsed their masters in that art. The Phœnicians affected no empire but that of the sea, and seemed to aim at nothing but an unmolested enjoyment of their trade. This they extended to all the known parts to which they could reach; to the British isles, commonly understood by the Cassiterides; to Spain, and other places in the ocean, both within and without the straits of Gibraltar; and, in general, to all the parts of the Mediterranean, the Black sea, and the lake Mæotis. In all these parts they had settlements and correspondents; and thus they exercised the great branches included under the term trade, *viz.* importation, exportation, and transportation, in full latitude. Besides this maritime commerce, they had an inland trade in Syria, Mesopotamia, Assyria, Babylonia, Persia, Arabia, and even India, which was of no less extent, and which may serve to give us an idea of the wealth of these people, and how deservedly their merchants are mentioned in scripture as equal to princes. (H. xxiii. 8.) Their country, though small, was the great storehouse that contained every thing which could administer to the necessities or luxuries of mankind, which they distributed to others as they judged would be best for their own interest. Their own commodities were, as we have observed already, the purple of Tyre, the glass of Sidon, and the exceeding fine linen made in their own country; these and other curious pieces of art, in metals and wood, seem to have been the chief, and almost only commodities of Phœnicia itself. Their territory was so small, as not to afford any export of their own growth; and, indeed, it is more likely that they wanted, than abounded with, the fruits of the earth. Their commerce and navigation derived peculiar advantage from their shipping, and they had excellent means for providing themselves with ships. Their larger embarkations were of two sorts, round ships, or gauli, and long ships, gallees, or triremes. When they drew up in line of battle, the gauli were disposed at a small distance from each other in the wings, or in the van and rear; and their triremes were contracted together in the centre. In order to discourage other nations from engaging in commerce, they practised piracy, or pretended to be at war with such as they met when they thought themselves strongest. This was a natural stroke of policy in people who grasped at the whole commerce of the then known world. At Tyre was the famous fishery already mentioned, which contributed so much to enrich that city. In connection with the navigation of the Phœnicians, we might mention their voyages in the service of Solomon; and the long voyage which some of them are said to have undertaken in the service of Necho, king of Egypt, round Africa, sailing out of the Red sea, and returning by the way of the strait's mouth, in which they employed three years.

Historical Revolutions.—Phœnicia, as we have already observed, was divided into several small kingdoms, of which some were confined within the narrow bounds of one city, and

and its territory. Of all the kings of Phœnicia, those of Sidon, Tyre, and Arad, seem to have been the most powerful and wealthy, and they certainly make the most conspicuous figure in history; but their successors, and the years of their respective reigns, are involved in obscurity and uncertainty, and interrupted by so many chasms, that it is not possible to give a regular detail of their transactions. For such an account as authentic history furnishes, we refer to the respective articles, *Sidon*, *Tyre*, and *Arad*.

After a variety of vicissitudes, Phœnicia fell under the power of the kings of Babylon. Nabopolassar, whose reign commenced in the year 626 B.C., became master both of Palestine and of Egypt. Tyre, after a resistance of 30 years, was taken in the year 573 B.C. But with the death of Baal, the title of king became extinct; and Phœnicia was for a considerable time governed by judges. Gerotratus was the last of these magistrates; and when he died in the year 554 B.C., the Tyrians sent to Babylon for another governor. Merbal was appointed, with the title of king, and reigned four years. He was succeeded by his brother Iram, or Hiram, in 550 B.C.; and in the 14th year of his reign, Cyrus, according to the Phœnician annals, made himself master of the Persian empire. At this time Phœnicia comprehended the whole coast from the vicinity of Aradus northwards to the frontiers of Egypt. It now became one of the provinces of Persia, and without making any conspicuous figure in history, it sustained itself by its commerce. When Phœnicia at a subsequent period was joined to Syria, it was governed by presidents or rulers sent from Rome. Phœnicia was afterwards one of the provinces which Antony abandoned to Cleopatra; but after the death of both these, Augustus, who passed into Palestine with Herod, granted to him several towns of Phœnicia. This province was one of the scenes in which the apostles and followers of Jesus Christ preached the doctrines of Christianity; but the hatred of the Jews against the Christians excited great troubles: the whole country was in arms, and the Jews revolted against the Romans, till at length Jerusalem was taken by Titus. The succeeding emperors distinguished some of the towns of Phœnicia by their attention. Tyre, among others, received from Adrian, and also from Severus, the title of Metropolis; so that Phœnicia, having its metropolis, was detached from the government of Syria. Under the reign of Theodore, and under that of Arcadius, this province was divided into two distinct parts: one was called "Maritime Phœnicia," or simply "Phœnicia;" and the other, "Phœnicia of Libanus." Maritime Phœnicia had for its metropolis Tyre, on which depended Sidon, Ptolemais, Berytas, Biblos, Tripolis, Arca, Orthosia, Botrys, Aradus, Antaradus, Porphyriion, Paneas, and Sylaminum. Phœnicia of Libanus had for its metropolis Damas, to which were subordinate Laodicea, Abila, Heliopolis, Jabrunda, Palmyra, Emisa, Danaba, Evaria, Comoara, Cotada, and Sarracene. Christianity flourished for some time in this province, till at length the Arabs gained possession of it; and Phœnicia, having embraced a new worship, was governed by different dynasties of Arabian princes.

PHŒNICĒ, one of the names which, according to Pliny, was given to the isle of Tenedos.

PHŒNICIAN CHARACTER. See CHARACTER.

PHŒNICON, in *Ancient Geography*, a town of Egypt, on the route from Coptos to Berenice, between Coptos and Didyme, according to Antonine's Itinerary.

PHŒNICOPTERUS, *Flamingo*, in *Ornithology*, a genus of birds of the order Grallæ, of which the generic character is, bill naked, toothed, bent as if broken; nostrils

linear; feet four-toed, palmate, the membranes semicircular on the fore part; the hind toe is not connected with the others. There are two species mentioned by Gmelin. The birds of this genus combine the characters of the Anseres and Grallæ. They have long legs and neck; the bill is large; the upper mandible carinate above, and toothed on the edge; lower compressed, transversely furrowed; the nostrils are covered with a thin membrane.

Species.

RUBRA, or Common Red Flamingo. This is specifically described as having its quill-feathers black. It inhabits Africa and South America. From the top of the bill to the end of the tail it is four feet four inches long, and to the end of the legs six feet; it feeds on aquatic insects and fish; perpetually twits its neck about when eating, so that the upper mandible touches the ground; it makes its nest on hillocks in shallow water, on which it sits with the legs hanging down, like a man sitting upon a stool; it lays two white eggs; is very impatient of cold; the flesh is good, especially the tongue; it changes its colour with its age, being the first year of a white ash, the second rosy, the third full scarlet; tongue covered with about twelve papillæ, which are hooked backwards, and cartilaginous at the tip. The young ones run about with great swiftness, but are unable to fly till they have attained nearly their complete growth. They subsist chiefly on small fishes, ova, and water insects; and frequent during the day the borders of rivers and lakes, withdrawing at night to the high grounds, and lodging amidst long grass. Flamingoes are extremely shy, and are said almost always, unless in the breeding season, to keep together in flocks, having a centinel ever vigilant at his post, by whom the slightest approaching danger is announced, by intimations which produce immediate flight. Their flesh is thought by some not to be inferior to that of the partridge.

CHILENSIS; Chili Flamingo. Quill-feathers white. It inhabits Chili; it is five feet long from the bill to the claws; the bill is covered with a reddish skin; head subcrested.

PHŒNICOPUS GALLINULA, a name by which some authors have called a bird, more usually known by the name tringa.

PHŒNICUM, in *Ancient Geography*, a town of Arabia Felix, upon the coast of the Elanitic gulf, between Hippos and Ahaunathi. Ptolemy.

PHŒNICURUS, in *Ornithology*, a species of *Motacilla*; which see. See also *MOTACILLA Eritbacus* and *Succica*.

PHŒNICUS MONS, in *Ancient Geography*, a mountain of Asia Minor, in Lycia. According to Strabo, it was also called Olympus.

PHŒNICUS Portus, a port of the Peloponnesus, in Messenia, near the promontory Acritas, south-west of Colonis.—Also, a port of the sea, on the east coast of Sicily, near the promontory Pachynus. Ptolemy.—Also, a port of the nome of Libya. Ptol.—Also, a port on the southern coast of the isle of Crete. Ptol.—Also, a port of Asia Minor, on the coast of Lycia, two miles from the town of Patara. Livy.—Also, a port of Asia Minor, on the coast of Ionia, at the foot of the promontory Mimas.

PHŒNICUSA, or PHŒNICODES, one of the seven Æolian isles of the ancients, called *Felicuda*, situated towards the west, to the east of the isle of Ericusa. It took its name, according to Strabo, from its production, which was the phœnix or palm-tree. See FELICUDA.

PHŒNICUSSÆ, a town of Asia, in Syria, which belonged to the Phœnicians.—Also, the name of two islands, placed

placed by Steph. Byz. on the coast of Africa, in the gulf of Carthage.

PHŒNIGMUS, *ῥομφαίος*, in *Medicine*, from *ῥομφή*, red, signifies properly that redness of the skin, which is occasioned by certain stimulating substances, multard, cantharides, &c. which have been therefore called *rufefacients*. The appellation of *phœnigmus* has also been sometimes given to the rufefacient substance itself.

Sauvages has applied the term to a disease, which consists of red or purple spots or blotches upon the skin, without any elevation, inflammation, or fever. His phœnigmus is, in fact, the *petechia sine febre* of some writers, and the *Purpura simplex* of Dr. Willan. See **PURPURA**. See Sauvages, *Nofol. Method.*, class x. gen. 32.

PHŒNIX, *Φοινῖξ*, in *Astronomy*, a constellation of the southern hemisphere; unknown to the ancients, and invisible in our northern parts.

The number of stars in this constellation is thirteen. See **CONSTELLATION**.

This constellation took its name and form from that of a bird famous among the ancients; but generally looked upon by the moderns as fabulous.

The naturalists speak of this bird as single, or the only one of its kind. They describe it as of the size of an eagle; its head finely crested, with a beautiful plumage; its neck covered with feathers of a gold colour, and the rest of its body purple; only the tail white, intermixed with carnation; and its eyes sparkling like stars. They hold, that it lives five or six hundred years in the wilderness; that, when thus advanced in age, it builds itself a funeral pile of sweet wood, and aromatic gums; then it fires it with the waisting of its wings, and thus burns itself; and from its ashes arises a worm, which, in time, grows up to be another phœnix.

Hence the Phœnicians gave the name phœnix to the palm-tree; because, when burnt down to the very root, it naturally rises again fairer than ever.

Ancient historians reckon four appearances of the phœnix: the first, in the reign of Sesostris; the second, in that of Amasis; the third, in that of the third Ptolemy; and the fourth, according to Dion Cassius, as a presage of the death of Tiberius, but Tacitus refers it to Egypt under the empire of Tiberius, and Pliny to the consulate of Quintus Plancius, which took place A.D. 36.

The ancients, however, speak of the phœnix as a fabulous bird.

The ancient Christians refer to the phœnix in some of their accounts of the resurrection.

PHŒNIX, in *Botany*, *ῥομφή* of the ancient Greeks, the Date Palm-tree; from which, as a primitive word, Phœnicia, the land of Palm-trees, seems to have derived its name; as likewise perhaps the red colour *phœniccus* or *purpiccus*, from the hue of the sheath when arrived at maturity; which etymology seems to us the more probable, as *purpiccus* is sometimes made synonymous with *croceus*, fallow-coloured. Linn. Gen. 573. Schreb. 776. Willd. Sp. Pl. v. 4. 730. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 369. Juss. 38. Lamarec Illustr. t. 893. Gært. n. 9.—Class and order, *Diœcia Triandria*. Nat. Ord. *Palme*.

Gen. Ch. Male, *Cal.* General sheath of one valve, including a branched stalk. Perianth deeply three-cleft, minute, permanent. *Cor.* Petals three, concave, ovate, rather oblong. *Stam.* Filaments three, very short; anthers linear, quadrangular, the length of the corolla.

Female either on a different plant, or on the same common stalk. *Cal.* and *Cor.* as in the male. *Pistil.* Germen superior, roundish; style awl-shaped, short; stigma acute. *Peric.* Drupa ovate, of one cell. *Seed* solitary, bony,

elliptic-ovate, marked with a longitudinal furrow, nearly opposite to the dorsal embryo.

Eff. Ch. General sheath of one valve.

Male, Calyx in three deep segments. Petals three.

Female, Calyx in three deep segments. Petals three. Pistil one. Drupa ovate.

1. *Ph. dactylifera*. Common Date Palm-tree. Linn. Sp. Pl. 1658. Ait. n. 1. Stokes Mat. Med. v. 4. 519. (Palma; Kämpf. Amoen. 667. t. 1, 2, 3. Math. Valgr. v. 1. 198, 200. Camer. Epit. 124. Ger. Em. 1517.)—Leaves pinnate, without thorns; leaflets linear-lanceolate, folded, straight.—Native of the Levant. Though it has been cultivated in our stoves for above 200 years, no individual has yet been preserved long enough to blossom, and very few have become caulescent. In the south of France this plant forms a handsome tree, but brings no fruit to perfection. It is well known, that as the male and female flowers are generally the produce of distinct individuals, the two sexes require to be cultivated together, in order to obtain good fruit; and in this chiefly consists the culture of the Palm-tree. Hence the Linnæans have derived one of their most striking proofs of the sexes of plants, the fact being recorded by those who were not instructed in that doctrine. (See **FECUNDATION**, and **SEXES OF PLANTS**.) For an account of the fruit, see **DATE**. The tree is of slow growth, but gradually attains a very lofty stature, consisting of a straight simple scaly trunk, crowned with a noble spreading evergreen tuft of long, pinnate, rigid, smooth leaves. (See **PALMÆ**.) Several axillary drooping bunches of innumerable white flowers, each bunch enveloped in a large coriaceous sheath, proceed from the crown of the stem, and produce an ample crop of dates, which are gathered in the East with great care and ceremony, constituting an important article of food, as well as of commerce. Their quality is as various as that of apples, or any other cultivated fruit. An ample and complete history of this valuable tree, and its whole economy, is to be found in Kämpfer.

2. *Ph. reclinata*. Reclining Date Palm-tree. Jacq. Fragm. 27. t. 24. Ait. n. 2.—Leaves pinnate, without thorns; leaflets linear-lanceolate, folded, loosely spreading.—Native of the Cape of Good Hope, whence it was sent to Kew by Mr. Masson, in 1792. It is kept in the greenhouse, but has not flowered.

3. *Ph. farinifera*. Small Date Palm-tree. Roxb. Coromand. v. 1. 53. t. 74. Ait. n. 3.—Leaves pinnate, without thorns; leaflets linear-awl-shaped, folded. Flowers with six stamens and three styles.—Native of Coromandel, chiefly found in dry barren sandy places, not far from the sea, flowering in January and February, and ripening fruit in May. The trunk is not above one or two feet high, and entirely enveloped in leaves, which resemble those of the first species in general appearance, but are more pointed, and of a much deeper green. The common flower-stalk, or *spadix*, bears numerous simple branches, each from eight to twelve inches long, beset with a great number of sessile flowers; the male white; the female green, on a separate tree. The stamens are six, with a three-cleft rudiment of a pistil. The pistil of the female flowers is three-cleft, and there are rudiments of three seeds, as Dr. Stokes well remarks; all which does not accord with the generic character, taken from the first species. Yet Dr. Roxburgh says the pistil is “as in *Phœnix dactylifera*.” Probably the character of the latter requires emendation, for which we can only look to some tropical botanist. The fruit of the present species is a purple single-seeded drupa, the size of a large French bean, containing a small quantity of sweet mealy

mealy pulp, and is eaten by the natives of the coast of Comandel, without any preparation. The stem of the plant contains a large quantity of farinaceous substance, among the woody fibres, affording an inferior sort of fago, to which recourse is had in times of scarcity; but Dr. Roxburgh describes it as bitterish, and inferior in nutritious qualities to real fago. This species is cultivated at Kew, having been procured from India in 1800, by Sir Joseph Banks.

Ph. pufilla, Lour. Cochinch. 614. Gært. v. 1. 24. t. 9, answers very nearly to the description of the last, except that the style is said to be short, and stigma simple. Perhaps the young styles cohere, and appear to be only one. Gærtner's figure indicates the rudiments of three seeds in the germen, as in Roxburgh's plant.

PHŒNIX, in *Gardening*, contains a plant of the evergreen exotic tree kind, of which the species cultivated is the date palm-tree (*P. dactylifera*).

Method of Culture.—This plant may be increased by seed, procured from abroad, or taken out of the fruit, which should be sown as soon as possible in pots of light rich earth, plunging them in a tan hot-bed in the stove, giving moderate waterings; when they soon come up. And when a few inches high, they should be pricked out into separate small pots, plunging them into the hot-bed or bark-bed, where they must remain, giving frequent waterings, and shifting them into larger pots, according as their progress of growth may require. When they are removed, great care should be taken not to injure their large roots, or to over-pot them.

This, like the rest of the palm tribe, has no other branches than its large leaves, each of which is composed of a leaf and branch, always arising from the top; and as the old leaves fall, the stem forms itself, and advances in height. But although the leaves grow very tall in a few years, the stem advances but slowly, and can never be expected to arrive at a flowering and fruiting state in this climate: it, however, merits a place in the hot-house collections for its singularity.

The berries of this tree are the dates of the shops, which are imported from Africa, and the countries in the Levant.

PHŒNIX, *Φωνίξ*, among the *Ancients*, a musical instrument, not unlike the *cithara*; which see. See also PHŒNIX.

PHŒNIX, in *Geography*, a part of Asia Minor, on the coast of Lycia.—Also, a mountain of Asia, in the Doride.—Also, a town of Italy, according to Appian.—Also, a river of Greece, in Thessaly, which ran into the Apidanus.—Also, a river of the Peloponnesus, in Achaia, which had its mouth south-west of the gulf of Corinth.

PHEOPUS, in *Ornithology*, a name used for two different birds; the one called by the Germans *brachvogel*, and the other the *whimbrell*, or *arquata minor*, the small curlew of authors.

The first of these, or the *brachvogel*, is of a deep black colour, spotted with a yellowish and reddish-brown; its beak is long, slender, and black, and is moderately bent; its neck is grey, tending to redness towards the bottom; and its belly is white. Mr. Ray suspects this not essentially to differ from the other, but the sight of the bird alone can determine that. See SCOLOPAX *Arquata*.

PHOGOR, in *Ancient Geography*, a mountain of Palestine, on the other side of Jordan.—Also, a town of Palestine, in the tribe of Judah, near Bethlehem.—Also, another town north-east of the Dead sea and of Livias.

PHOKWARAH, in *Geography*, a town of Hindoostan, in Lahore; 50 miles E. of Sultanpour.

PHOLAS, in *Conchology*, a genus of the class and order Vermes Testacea. The generic character is, animal an ascidia; shell bivalve, divaricate, with several lesser differently shaped accessory ones at the hinge; the hinge recurved, united by a cartilage; in the inside, beneath the hinge, is an incurved tooth. There are twelve species. The inhabitants of this genus all perforate clay, spongy stones, and wood, while in the younger state; and as they increase in size, they enlarge their habitation within, and thus become imprisoned. They contain a kind of phosphoric liquor, of great brilliancy in the dark, which illuminates whatever it happens to fall on.

The word pholas is derived from the Greek *φαλαξ*, and signifies no more than any thing which is hidden; the name was given to this genus of shell-fish from their custom of making themselves holes in earth, sand, stones, or wood, and living hidden in them. Many being of opinion, that these could not work themselves into the substance of hard stones, have thought that they were hatched in holes accidentally formed in stones, and that the shells naturally grew of such a shape as was necessary to fill the cavity. Nor is this the only error propagated concerning the pholas; for as all that was signified by the name being only that the shell was hidden in some solid substance, whenever an author found a shell-fish of whatever kind thus buried in stone, he described it under the name of pholas.

Species.

* *DACTYLUS*. Shell oblong, with reticulate subspinous striæ on the upper part. It is found among rocks in this country, and other parts of Europe, and shines by night. It is about five inches long; entirely white, with sometimes an ochraceous cast, thin, fragile, elongated, and wedge-shaped on the fore part, convex behind, the margin inflected; it is marked with subspinous striæ, which become gradually more indistinct; the hinge resembles a spoon, and there are four accessory valves.

COSTATA. Shell ovate, and striate with elevated ribs. It inhabits the American seas. It is white, and almost six inches long; the ribs are oblique, and armed with elevated scales or obtuse spines.

STRIATA. Shell ovate, and multifariously striate. This species is found in some of the southern parts of Europe and India, and the coast of Barbary. The striæ are occasionally decussate; the part near the hinge is glabrous, and without striæ.

CANDIDA. Shell oblong, and muricate on all parts with decussate striæ. This inhabits European and American seas, and is very thin; it is silvery within, and more glabrous; rounded at each end; tooth of the hinge is slender and cleft; length near an inch, the breadth an inch and a half.

PUSILLA. Shell oblong, rounded with arched striæ. It is found in different parts of India and America, and penetrates the bottoms of ships. The shell is brownish or white, gaping on the fore part, globular under the top, and marked with reticulate knotty striæ.

* *CRISPATA*. Shell oval, the part next the hinge more obtuse, waved, and striate; teeth of the hinge curved, large, and strong. A variety is known by the shell being thinner and smaller; the tooth also is slender and oblique. It inhabits European seas, is about two inches long, and three and a half broad. The primary shells are divided by a transverse wrinkled groove in the middle; the accessory ones are small.

ORIENTALIS. Shell oblong, with a straight margin; one-half of it is quite smooth, the other with reticulate striæ. It inhabits Siam and Tranquebar; is large and thin; the shells gape at one end only, and they are marked within with reticulate striæ.

CAMPECHIENSIS. The shell of this species is narrow, white, and very finely striate. It inhabits the bay of Campeachy. It is probably not a distinct species.

CORDATA. Shell short, turgid, and furrowed with fine elevated transverse striæ; aperture heart-shaped. It is found affixed to the Corals. The shell is very thin, fragile, and of a dirty white; the fore part is smooth, except a few arched ridges.

CHILENSIS. Shell oblong, a little depressed, with distant longitudinal striæ. It is found about the rocks of Chili. The shell is five inches long, with minute appendages.

TEREDULA. Shell oblong, white, with a longitudinal brown granulate suture. It inhabits the Belgic shores, and penetrates timber.

HIANS. Shell bivalve, white, with transverse arched striæ; above connivent, convex in the middle, beneath wedge-shaped, with a very large oval aperture. It inhabits the American islands, and perforates calcareous rocks and corals.

As to the luminous quality of this species of shell-fish, observed by Pliny, and by modern naturalists, see **DACTYLUS**.

For an account of a particular species of pholas, called by Dr. Parsons *pholas conoides*, by others *pholas lignorum*, and in Dutch *wood-muscle*, because it is found burrowed in timber, see Phil. Transf. vol. lv. p. 1, &c.

PHOLIDIA, in *Botany*, from $\varphi\omega\lambda\iota$, $\varphi\omega\lambda\iota\delta\omicron\varsigma$, the scale of a fish or serpent; alluding to the scaleiness of the corolla. Brown Prodr. Nov. Holl. v. 1. 517.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Myoporina*, Br.

EST. Ch. Calyx deeply five-cleft, unchanged in the fruit. Corolla funnel-shaped; tube longer than the calyx; throat dilated, tumid at one side; limb short, irregular; its upper lip two-lobed, recurved; lower spreading, in three deep equal segments. Stamens included. Anthers bearded. Stigma capitate, emarginate. Drupa dry, of four cells, with four seeds.

1. *Ph. scoparia*. Found by Mr. Brown, on the fourth coast of New Holland. A rush-like shrub, with opposite awl-shaped leaves. Stalks single-flowered, axillary, solitary, without bractæas. Corolla blue, clothed externally with minute scales. Albumen thin.

PHOLIS, in *Natural History*, the name of a genus of fossils of the class of the gypsums or plaster-stones, the distinguishing characters of which are, that the bodies of it are considerably hard, composed of somewhat broad particles, and of a bright crystalline lustre.

The word is derived from $\varphi\omega\lambda\iota$, a scale, or small flake, from these bodies being composed of particles of that form.

The species of this genus are the most valuable of all the gypsums, as burning to the best and finest plaster; but so far as is yet known, there are but two of them: the fine plaster-stone of Montmartre in France, called by us *plaster of Paris stone*, and *parget*; and the other the coarser and somewhat reddish kind, common in many parts of England, and called *hall plaster*. Hill. See **PARGET**.

PHOLIS, in *Ichthyology*, the name of a small anguilliform fish, the back of which is brown, the belly white, and the whole back and sides spotted, and the skin soft and not cov-

ered with scales, but with a tough mucilaginous matte like the eel.

This most of all approaches to the alauda, and though usually somewhat larger, yet Mr. Ray doubts whether it really differs from it in any thing essential; its great distinction being its colour, which, though a very obvious, is a very precarious one.

This is the **BLENNIUS Pholis** of Gmelin, and the blennius of Artedi, with the top of the head acuminate, and the upper jaw the larger, the alauda non cristata of Rondeletius and Gesner, the mulgraave and bulcaud of Willughby and Ray, and the smooth blenny of Pennant. It is found on the shores of the European ocean and Mediterranean sea, and at the mouths of rivers among rocks and algæ, &c. See **BLENNIUS**.

PHOLLIDES, a word used by the ancient physicians for soft and fungous tumours of the legs, such as those of people in anasarca, or leucophlegmacy.

PHOLLIS, as a coin. See **FOLIS**.

PHOLOC, in *Ancient Geography*, a mountain of Triphylia, south of Onus.—Also, a mountain of Greece, in Thessaly, where Hercules is said to have slain the Centaur.—Also, a small town of the Peloponnesus, in Arcadia, west of the river Erymanthe, according to Pliny and Mela. A mountain of the same name was situated near it to the west, which was the boundary of the Elide.

PHOMOTHIS, a town of Asia, in the Marcotide, according to Ptolemy.

PHONASCIA, $\varphi\omega\lambda\iota\sigma\kappa\iota\alpha$, derived from $\varphi\omega\lambda\iota$, voice, the art of forming the human voice.

In ancient Greece, there were combats or contests established for the voice, as well as other parts of the gymnastice.

The combats continued to be held in the time of Galen; and they were these that brought the phonascia into vogue. Hence the masters of this art, and those who taught the art of managing the voice, were called *phonasci*, $\varphi\omega\lambda\iota\sigma\kappa\iota\sigma\tau\alpha\iota$; and under their tutorage were put all those destined to be orators, singers, comedians, &c.

PHONIA, in *Geography*, a town of European Turkey, in the Morea; 22 miles W.S.W. of Corinth.

PHONICS, $\varphi\omega\lambda\iota\sigma\kappa\iota\alpha$, derived from $\varphi\omega\lambda\iota$, voice, or sound, the doctrine or science of sounds (which see); otherwise called *acoustics*; which see.

Phonics may be considered as an art analogous to optics; and may be divided, like that, into *direct*, *refracted*, and *reflected*. These branches the bishop of Ferns, in allusion to the parts of optics, denominates *phonics*, *diaphonics*, and *cataphonics*.

Phonics is improveable, both with regard to the object, the medium, and the organ.

As to the object, sound, it may be improved, both with regard to the production and the propagation of sounds. The first, in speaking or pronouncing, in whistling or singing, or hallooing or luring, which are all distinct arts, and all improveable. The second, by the position of the sonorous body.

With regard to the medium, phonics may be improved by the thinness and quiescency thereof, and by the sonorous body being placed near a smooth wall, either plane or arched, especially cycloidally or elliptically; whence arises the theory of whispering places.

Add to these, that by placing the sonorous body near water, its sound is mollified; that by placing it on a plain, the sound is conveyed to a greater distance than on uneven ground, &c.

As to the organ, which is the ear, it is helped by placing

it near a wall, especially at one end of an arch, the sound beginning at the other; or near the surface of water, or that of the earth.

And also by instruments, as the sceptorophonicon, or speaking-trumpet.

Also by an instrument to help weak ears as spectacles do eyes; by an instrument to take in vastly remote sounds, as telescopes do objects; by a microphone, or magnifying ear-instrument; and by a polyphone, or multiplying ear-instrument.

Cataphonics, or reflected hearing, may be improved by several kinds of artificial echoes; for, in general, any sound falling, either directly or obliquely, on any dense body of a smooth surface, whether plain, or arched, is beat back again, or reflected, *i. e.* it echoes more or less. See ECHO.

PHONICUM CENTRUM. See CENTRUM.

PHONOCAMPTICUM CENTRUM. See CENTRUM.

PHOORY, in *Geography*, a town of Hindoostan, in Baglana; 28 miles S. of Zolnani.

PHORA, in *Ancient Geography*, a town of Asia, in Greater Armenia, between Tasco and Mapa, according to Ptolemy.

PHORAGA, a town of Asia, in Aria. Ptolemy.

PHORBÆ, a town of Thessaly, which belonged to the Achæans; called also *Phorbæ*.

PHORBANTIA, an island on the coast of Sicily. Ptolemy.

PHORBANTIUM, a mountain of Thessaly, in the Trazena. Steph. Byz.

PHORBEIA, *φορβεία*, a musical instrument of the ancients, implies a *capistrum* or leather bandage, with which the players on the flute surrounded their heads. The phorbeia was placed before the mouth of the musician, opposite to which was a slit for the reed to pass through. See FLUTE.

This bandage was used for the purpose of augmenting the force of the wind, and not only to prevent the swelling the cheeks of the performer, but to prevent the wind from escaping at the sides of the reed. See CAPISTRUM.

PHORCYNUS, in *Ancient Geography*, a port of the isle of Ithaca, mentioned by Homer, and also by Strabo.

PHORIMOS, a name given by some authors to rock alum.

PHORINE, a word used by some authors to express the skin of a hog; some also understand it to mean a skin of any kind, extending it even to the human cutis.

PHORMINX, an ancient musical instrument, seems to have been the largest kind of lyre. See LYRE.

PHORMIUM, in *Botany*, a name adopted by Forster from the ancient Greeks, whose *φορμιον* was used for making mats, or baskets, being so called from *φορμος*, a basket or pannier. Forster's plant serves for similar purposes in New Zealand. Forst. Gen. t. 24. Linn. Suppl. 28. Schreb. 799. Willd. Sp. Pl. v. 2. 171. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 284. Juss. 52. (Lachenalia; Lamarck Illustr. t. 237. f. 2. Chlamydia; Gært. t. 18.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronaria*. Linn. *Asphodeli*, Juss.

Gen. Ch. *Cal.* none. *Cor.* Petals six, obliquely ascending, oblong, converging into a tube, united at the base, unequal; the three outermost acute, keeled; the three innermost longer, reflexed rounded and vaulted at the extremity, slightly emarginate. *Stam.* Filaments six, thread-shaped, ascending, longer than the corolla; anthers erect, nearly triangular. *Pist.* Germen superior, oblong, obtusely triangular; style thread-shaped, nearly erect, rather

shorter than the stamens; stigma simple. *Peric.* Capsule oblong, pointed, with three furrowed angles, three cells and three valves; the partitions from the middle of each valve. *Seeds* numerous, imbricated in two rows along each partition, ovate, black and shining, compressed, bordered.

Ess. Ch. Corolla inferior, of six petals; the three inner ones longest. Stamens prominent. Capsule oblong, triangular. Seeds compressed, bordered.

1. *Ph. tenax*. New Zealand Flax. Forst. Prodr. 25. Linn. Suppl. 204. Cook's Voyage, v. 2. 96. t. 96. J. Mill. Ic. t. 2.—Native of New Zealand and Norfolk Island. Hardy in our climate, flowering in June and July, but rarely. *Root* perennial, long, with many strong fibres. *Stem* none. *Leaves* radical, numerous, erect, linear, acute, keeled, entire, smooth, four or five feet long, tough and rigid, of a glaucous green; stained with orange-colour about the lower part. *Flower-stalk* radical, branched, many-flowered. *Flowers* yellow, each about an inch and a half long. *Capsule* three inches long. Very strong and good thread may be manufactured from the fibres of the leaves.

PHORMORAPHIS, in the *Materia Medica*, a name often used by the later Greek writers, and generally looked on as one of their unintelligible words, or the name of some drug not known at this time. See CARPESIA.

PHORONICUM, in *Ancient Geography*, a name given by Pausanias and Steph. Byz. to a town of Argos, the capital of the Argolide.

PHORONOMIA, derived from *φορα*, motion, and *νομος*, law, is a science comprehending the laws of motion, both of solids and fluids. The work of Hermannus, printed at Amsterdam in quarto, in 1715, under this title, is well known.

PHORONTIS, in *Ancient Geography*, a town of Asia Minor, in Caria. Pliny.

PHORUM, a port of Greece, in Attica, in the vicinity of Pnyttalia. Strabo.

PHOS, a word used by some medical writers to express a distemperature of the eye, in which there is seen a black circle wholly surrounding the pupil.

PHOSCAS, in *Ornithology*, a name of a fresh-water fowl of the duck kind, and of the size of the common wigeon. Its body is remarkably flat; its beak and legs are blue; its head and neck are of a brownish colour, variegated all over with numerous triangular black spots.

PHOSGENE GAS, in *Chemistry*, a species of gas lately discovered by Mr. John Davy, in his efforts to unite together the carbonic oxyd and the oxymuriatic gases. Some unsuccessful attempts had been made for this purpose by Messrs. Gay-Lussac and Thénard, and afterwards by Mr. Murray of Edinburgh. Mr. Davy accomplished this object apparently without any difficulty. The gases were put in contact and exposed to a bright light for a quarter of an hour; when the mixture was diminished to half its original bulk, and a gas was left, which possessed several remarkable properties. It is composed of equal volumes of chlorine and carbonic oxyd gases, condensed into half their bulk. It is colourless; and has a strong disagreeable smell. Its specific gravity is 3.669; and 100 cubic inches, under a mean temperature and pressure, weigh 111.91 grains; hence it is by far the heaviest gas at present known. It reddens vegetable blues. It combines with ammonia, condensing four times its bulk of that gas, and forming a peculiar neutral salt. Phosgene gas is decomposed by water, and by most metallic bodies. It is an acid of a very peculiar nature, and deserves a much more complete examination. As this gas has been hitherto produced only by the action

of light, Mr. Davy proposed to name it "phosgene." *Phil. Transf. for 1812, part i.*

PHOSPHATS, are salts formed by the phosphoric acid, with the different saline bodies. See the respective bases, as POTASH, SODA, &c.

PHOSPHITES, salts formed by the phosphorous acid combining with the bases of salts.

PHOSPHOLITE. See APATITE.

PHOSPHORI, or *Phosphorescent Substances*, may be distributed into three classes. The first comprehends those which require a previous exposure to the solar or other light, in order to become luminous; on which account they are called "solar phosphori." See PHOSPHORUS.

The second class includes those which, without any necessary previous exposure to light, become luminous when moderately heated; these, by way of distinction, may be denominated "phosphori from heat." These differ from the former in that, after having been continued at any particular temperature till their luminousness is exhausted, they are incapable of becoming again luminous, except at a greater heat than that to which they were first subjected. The range of temperature at which these bodies become luminous, commences at about 400° Fahr., and terminates at the lowest visible red heat. In some the light is almost momentary; in others it remains many minutes. The intensity of the light appears to be unalterable, whether the body that emits it be in a Torricellian vacuum, or plunged in any of the natural or artificial gases. The following substances are arranged by Mr. T. Wedgwood, according to the brilliancy of their light. See *Phil. Transf. vol. lxxxii. p. 28.*

The most phosphorescent of all substances by heat, is that variety of the blue fluor of Derbyshire, which when scraped or struck emits a fetid bituminous odour; it glows, when moderately heated with a pale emerald green light, sufficiently intense to be very visible even in day light. To the second rank belong the common swine-stone, the common blue fluor, and red felspar, all of which, as well as those that follow, exhibit a white or reddish light. The third class includes the diamond, the ruby, carbonated barytes, chalk, colourless calcareous spar, sea-shells, granite, and white fluor. The fourth class comprehends white sand, carbonated magnesia, heavy spar, flint, white marble, quartz, porcelain, and earthen ware. The fifth class includes most of the metals, sulphat of potash, borax, white paper, white linen, sawdust, and asbestos. Under the sixth and last class are comprehended oil, wax, spermaceti, and butter when nearly boiling. To exhibit with the greatest effect the luminous property of these bodies, the harder ones should be coarsely pulverised and sprinkled in a dark room on the surface of a thick metallic plate, heated below redness. A very striking exhibition of the phosphorescence of the fetid blue fluor may be made by heating some oil in a clear flask till it becomes luminous, and then dropping in about a teaspoonful of pulverised fluor; at the instant when this latter comes in contact with the hot liquid, a bright flash of green light is given out, which may be renewed for many times, by repeatedly shaking the vessel. Most of the substances above mentioned, are phosphorescent also by friction. Sir H. Davy has also observed, that if fluor be heated till it ceased to become luminous, it is still capable of producing light by collision; and it is observed, that certain other bodies, as tremolite, and a particular variety of blende, give out much light even from the scratch of a pin.

The third class of phosphorescent substances, consists of those which, belonging to the animal and vegetable kingdoms, emit light spontaneously at the common temperature,

without the necessity of previous exposure to light: these may be denominated "spontaneous phosphori." Animal substances exhibit this appearance before the commencement of putrefaction; and it ceases when the putrefaction is complete. Among those who have directed their attention to this subject, we may reckon Boyle, Canton, and Dr. Hulme. See LIGHT.

PHOSPHORIA, $\Phi\omega\sigma\phi\omega\rho\iota\alpha$, in *Antiquity*, a festival in honour of Phosphorus or Lucifer.

PHOSPHORIC ACID, in *Chemistry*. This acid is found in combination with lime, soda, and ammonia in animal substances, and is also a component part of several minerals. It may be obtained, but not in a state of purity, from the bones of animals. For this purpose, the bones are first burned to whiteness in a red heat, and then reduced to a fine powder. This powder is decomposable by the sulphuric acid, by which means the phosphoric is set free in the liquid form, while the sulphat of lime is insoluble. This liquid, however, is found not to contain the phosphoric acid pure, but combined with some lime. Hence this process is not resorted to for getting pure phosphoric acid. The following is unobjectionable.

Into some hot nitric acid project small bits of phosphorus, till no more effervescence takes place. The nitric acid is decomposed, giving the whole of its oxygen to the phosphorus, while the nitrogen which constitutes the effervescence escapes in the form of gas. A thickish fluid results from this process, which, when evaporated in a platina crucible, still thickens till it is raised to a red heat. On cooling it assumes the solid form, and is transparent like glass. This is the pure phosphoric acid, which in this form is also called phosphoric glass. It possesses all the essential properties of an acid. It has a sharp acid taste, and changes vegetable blues to red.

Its affinity for water is such that it soon deliquesces in the air, exhibiting the same viscid oily appearance which it possessed before evaporation. It has no smell, not being volatile at less than a red heat, when it exhales in the form of white smoke.

In the state of glass its specific gravity is 2.516, which will be less in the liquid form as it contains more water.

It dissolves readily in water, producing heat, though much inferior to that produced by the combination of the sulphuric acid with water; a proof that the former has less attraction for water.

This acid is known to consist of 1 atom of phosphorus to 2 of oxygen. The atom of phosphorus being 9, and that of oxygen 7, will make the acid $9 + 14 = 23$, which is near the truth. It does not combine with more oxygen, although its affinity is great for that substance.

It is not decomposed in the cold by any of the inflammable bodies, the alkaline and earthy bases excepted. Charcoal, zinc, and iron decompose it, when assisted by a strong heat in a close retort, setting the phosphorus free. It is in this way that phosphorus is obtained. In its dilute state it acts on several of the metals, as zinc, tin, and iron. They are first oxydated by the water, when hydrogen gas is evolved. The acid then combines with the oxyd, forming salts, which are described under their respective bases. It combines with the alkalies, earths, and the rest of the metallic oxyds.

The experiments of Lavoisier and Dalton agree in making the proportion of oxygen to be what has been already stated. The former chemist found that 114 of the acid contained 69.375 of oxygen.

PHOSPHORIC Matches, or *Tapers*, are prepared by the following

following simple process. Take a glass tube, four inches long, and one line in diameter, closed at one end. Introduce a small quantity of phosphorus into the tube, and push it to its farther end; after which, a taper covered with a small quantity of wax is introduced into the same tube. The open end is then hermetically sealed, and the other end is plunged into boiling water; upon which the phosphorus melts, and fixes itself upon the match. A line is drawn at one end of the length of the tube, with a flint, that it may be broken, as occasion may require. The match is to be drawn out quickly to inflame the phosphorus.

The process of M. Lewis Pegle for making the inflammable bougies consists in taking a glass tube, five inches long, and two lines wide, one end of which is sealed with a blow-pipe. Small tapers of wax are prepared, with three double threads of cotton twisted together. The extremity of the match or taper is half an inch long, and must not be covered with wax. A piece of lead is laid in a faucer filled with water; and upon this the phosphorus is cut, beneath the water, into fragments of the size of a grain of millet. One of these grains is to be dried, and introduced into the tube of glass; after which the fortieth part of a grain of very dry sulphur is to be added, that is, half the weight of the phosphorus. One of the bougies is then taken, and its extremity dipped in very clear oil of wax. If too large a quantity rises, it must be dried with a cloth. The match is introduced into the tube with a turning or twisting motion between the fingers. The bottom of the tube must then be plunged into boiling water, to soften the phosphorus; observing to keep it no longer than three or four seconds in the water. The other extremity of the tube is afterwards sealed. These bougies must be kept in a tin tube, to avoid the danger of inflammation.

PHOSPHORIC Bottles, are formed by heating a glass bottle, and fixing it in a ladle full of sand; and then two or three small pieces of phosphorus are introduced into it. A small red-hot iron wire is used to stir the phosphorus about, and cause it to adhere to the internal surface of the bottle, where it forms a reddish coating. The heated wire is introduced repeatedly; and when all the phosphorus is thus distributed within the bottle, it is left open for a quarter of an hour, and afterwards corked. When this is used, a common match tipped with sulphur is introduced into the bottle, turned round, and quickly drawn out. The phosphorus which sticks to the sulphur takes fire, and lights the match.

The theory of this phenomenon depends upon the circumstance, that the phosphorus is strongly dried, or half calcined, and needs only the contact of air to set it on fire.

As phosphorus is soluble in oils, more especially the volatile oils, these oils become luminous. If this solution be kept in a bottle, a phosphoric flash, which emits a small quantity of light, will be seen every time the bottle is opened. The oil of cloves is used in this operation. The combination of phosphorus and oil appears to exist naturally in the glow-worm, or "*lampyris splendidula*" of Linnæus. Forster of Gottingen observes, that the shining matter of the glow-worm is liquid. If the glow-worm be crushed between the fingers, the phosphorecence remains on the finger. Henckel reports, in his eighth dissertation of his "*Pyritologia*," that one of his friends of a sanguine temperament, after having danced much, perspired to such a degree, that he thought his life in danger. While he undressed, lines of phosphoric flame were seen on his shirt, which left yellow red spots behind them, resembling the residæ of burned phosphorus. This light was long visible.

A phosphoric gas may be extracted from phosphorus, which takes fire by the mere contact of air. It is to the disengagement of a gas of this nature, that we may attribute the ignes fatui which play about burying grounds, and generally in all places where animals are buried and putrefy. It is to a similar gas, that we may refer the inflammable air which constantly burns in certain places, and upon the surface of certain cold springs. Chaptal's *Elem. of Chemistry*, vol. iii.

PHOSPHORICAL COLUMN. See **COLUMN.**

PHOSPHOROUS ACID, in *Chemistry*. When phosphorus is exposed to the air in an open vessel for a length of time, it gradually assumes the form of a thick fluid, of the appearance of oil. This is the phosphorous acid. The slowness with which it combines with oxygen only allows it to combine with 1 atom of oxygen, by which it is constituted. Its atom is, therefore, 9 of phosphorus with 7 of oxygen, equal to 16.

It is of a viscid oily consistence, having an acid taste, and the smell of garlic.

When exposed to heat some of the water evaporates, but the acid does not become concrete like the phosphoric. In this situation the water is decomposed. The oxygen combines with one portion of the phosphorous acid, forming the phosphoric acid. An atom of phosphorus combines with the hydrogen, forming phosphuret of hydrogen, which escapes in the form of gas. So that out of three atoms of phosphorous acid, and one of water, two atoms of phosphoric acid, and an atom of phosphuretted hydrogen, are formed.

If the phosphorous acid be exposed to the air for a considerable length of time after it is formed, it is converted into phosphoric acid.

When this acid with water is poured upon zinc, tin, or iron, the water is decomposed as with the phosphoric acid, but the hydrogen combines with phosphorus, forming phosphuretted hydrogen, which is known by the smell.

The sulphuric acid, when aided by heat, gives an atom of oxygen, which converts it into the phosphoric acid, while the sulphurous acid escapes in the form of gas. The nitric acid produces a similar change.

PHOSPHORUS, $\Phi\sigma\sigma\sigma\sigma\sigma\sigma$, formed from $\Phi\omega\varsigma$, *light*, and $\varphi\epsilon\gamma\omega$, *I bear*, a matter, which shines, or even burns, spontaneously, and without the application of any sensible fire.

Phosphori are either *natural*, or *artificial*.

PHOSPHORI, *Natural*, are matters which become luminous at certain times, without the assistance of any art or preparation.

Such are the glow-worms, frequent in our colder countries; lantern-flies, and other shining insects, in hot countries; rotten wood; the eyes, blood, scales, flesh, sweat, feathers, &c. of several animals; diamonds, when rubbed after a certain manner, or after having been exposed to the sun or light; sugar and sulphur, when pounded in a dark place; sea-water, and some mineral waters, when briskly agitated; a cat's or horse's back, duly rubbed with the hand, &c. in the dark; nay, Dr. Croon tells us, that upon rubbing his own body briskly with a well-warmed shirt, he has frequently made both to shine; and Dr. Sloane adds, that he knew a gentleman of Bristol, and his son, both whose stockings shone much after walking.

All natural phosphori have this in common, that they do not shine always; and that they never give any heat.

The natural phosphori are either *soluble*, *vegetable*, or *animal*.

PHOSPHORUS.

The fossile are, though very different in degree, some sorts of earths, white sand, limestones, stalactites, and several other figured stones, island crystals, flints, some species of agates, white arsenic; but no sort of metals, metallic or sulphureous bodies, as jet, amber, except the before-mentioned arsenic.

On the other hand, salts imbibe light, provided they are divested of every metallic principle; otherwise not, though as pellucid as possible. For this reason none of the vitriols will imbibe light; but other salts will though with a considerable difference as to quantity; for sal gem and rock salt imbibe very little; sea salt, if dry, and in crystals, much more; and, in like manner, sal ammoniac, sal catharticum, and nitre yet more. This power is weak in the natron of the ancients, and alum; but brightest of all in borax.

In the vegetable kingdom we find very few phosphori; that of dry rotten wood is weak and not lasting; it appears chiefly upon the edges and inequalities of the surface. But this is most remarkable in the rotten wood of the fir-tree, and some others, where, in the dark, you see shining spots as big as tares; whereas in full light the whole surface appears alike. Some few bars are luminous, but not considerably so; but no fruits, seeds, or their meals. Cotton, and the crystals of tartar, appear very bright, but fine loaf-sugar appears the most luminous of all both without and within; gums and resins retain no light.

There is a vast variety of phosphori in the animal kingdom, such as the bones and teeth; to these may be added the shells of fish, egg-shells, the human calculus, bezoar, and those parts of animals in which the terrestrial principle is very predominant. But where there is a considerable quantity of oily matter, as in the hoofs, horns, and feathers, no light is manifest, or at least in a small degree. Light is visibly retained by the skins of several living animals. Water cannot be made to imbibe light, though ice does exceedingly well, and especially snow.

Beccarius proposes some queries concerning the natural phosphori, of which the first is, in what and how great a light the object ought to be placed? He tried different phosphori, in different degrees of light, and found them imbibe most light from the sun itself; next in quantity when the sky was clear; and the least in foggy weather. These experiments should be made in the open air, and not in a house with the glass-windows shut; because many bodies appear luminous when the light has come directly to them, which will not have that appearance when the light has passed through the glass. He lastly tried what light they would imbibe from very bright flame, and found that alabaster itself, which is saturated more than any substance by the sun's rays, imbibed exceedingly little. The next query is, how long these bodies should remain in the light to be sufficiently saturated? Four or five seconds were found the utmost length of time required for that purpose. The other query is, how long the received light will continue in these phosphori? It does not last the same time in all; but continues more or less, from two seconds to eight, in proportion to the strength of the phosphorus, and the quantity of light received.

But that which, of all natural phosphori, has occasioned the greatest speculation, is the

PHOSPHORUS, *Barometrical*, or *Mercurial*. M. Picard first observed, that the mercury of his barometer, when shaken in a dark place, emitted light; with this circumstance, that in shaking the mercury with rapidity, sometimes above, and sometimes below its equilibrium with the air,

the light was only seen when below it, where it appeared as if adhering to the upper surface.

But this light is not found in the mercury of all barometers; which occasions a great difficulty.

M. Bernouilli, upon examining the circumstances of this phenomenon, invented a solution of the same; he imagines, that upon the mercury's descending, the vacuum in the tube increasing, there issues out of the mercury to fill up this excess of vacuity, a very fine subtile matter, before dispersed throughout the pores of this mineral; and that, at the same time, there enters through the pores of the tube another fine matter: thus, the first matter emitted from the mercury, and collected over its surface, striking impetuously against that received from without, has the same effect with Descartes' first element against the second; that is, it produces the motion of light.

But why, then, is not the phenomenon common to all barometers? To this he answers, that the motion of the subtile matter out of the mercury may be weakened, and prevented, by any heterogeneous matter collected on its upper surface, into a kind of pellicle, so that the light should never appear, but when the mercury is perfectly pure. This reasoning seemed confirmed from the experiments of several barometers, which he made according to this plan; but the Royal Academy of Sciences, repeating experiments with barometers made after the same manner, did not meet with the same success; the light being found in some, but not in others.

M. Homberg, therefore, conjectured, that the difference consisted in the different qualities of the quicksilver: in some, he observed, they used quick-lime to purify it; in others, steel-filings. The mercury, then, rising in the distillation, and passing through the lime, might take away some parts thereof, capable, by their extreme smallness, of lodging in its interstices.

Hence, as quick-lime always retains some fiery particles, it is possible, in a place void of air, where they swim at liberty they may produce this lustre.

Mr. Hauksbee has several experiments on the mercurial phosphorus. Passing air forcibly through the body of quicksilver, placed in an exhausted receiver, the parts were violently driven against the side of the receiver, and gave all round the appearance of fire; continuing thus till the receiver was half-full again of air.

From other experiments he found, that though the appearance of light was not producible by agitating the mercury in the same manner in the common air, yet that a very fine medium, nearly approaching to a vacuum, was not at all necessary.

And, lastly, from other experiments he found, that mercury inclosed in water, which communicated with the open air, by a violent shaking of the vessel wherein it was inclosed, emitted particles of light in great plenty, like little stars.

By including the vessel of mercury, &c. in a receiver, and exhausting the air, the phenomenon was changed; and, upon shaking the vessel, instead of sparks of light, the whole mass appeared one continued circle of light. Farther, if mercury be inclosed in a glass tube, close stopp'd, that tube is found, on being rubb'd, to give much more light, than when it had no mercury in it. When this tube has been rubb'd, after raising successively its extremities, that the mercury might flow from one end to the other, one sees a light creeping in a serpentine manner all along the tube; that is to say, the mercury is all luminous. The mercury, being made to run along the tube afterwards

PHOSPHORUS.

afterwards without rubbing it, was found to emit some light, though much less than before: this proves that the friction of the mercury against the glass, in running along, does in some measure electrify the glass, as the rubbing it with the hand does, only in a much less degree. This is more plainly proved by laying some very light down near the tube, for this will be attracted by the electricity raised by the running of the mercury, and will rise to that part of the glass along which the mercury runs; and it is very plain from this, that what has been long known in the world under the name of the phosphorus of the barometer is not a phosphorus, but merely a light raised by electricity, the mercury electrifying the tube. Phil. Trans. N^o 484. See ELECTRICITY and MERCURY.

PHOSPHORI, *Artificial*, are such as owe their luminous quality to some art or preparation.

Phosphori are, it is well known, often produced by art; some are made by the maceration of plants alone, and without any fire; such as thread, linen cloth, but above all paper. The luminous appearance of this last, which is now known to be an electrical phenomenon, is greatly increased by heat. This is confirmed by two experiments; the first is, by exposing the paper, spread upon an iron grate, to the naked fire, yet not near enough to scorch it, and then laying a warm brick thereon to retain the heat; by which means it was observed, that where the paper was not screened by the iron grate, it was most luminous; so that by the lights and shades you might distinguish in the dark the image of the iron grate a considerable time. The other experiment is, the application of the paper to a plate of warm brass; from which, when in the dark, you might very easily, by its being less luminous, distinguish the margin of the paper that had not been warmed by the brass.

However Beccarius, though he acknowledges that paper, after having been made red-hot and cooled again, is an excellent phosphorus, found, that it was much injured by being exposed to the light of the sun. He made experiments to the same purpose with a great variety of substances, mineral, vegetable, and animal; and observed, that the effects were the same, and that the stronger the light was, and the longer they were exposed to it, the more injury they received: and he found also, that the injury they received was lasting.

The same author takes notice also of those phosphori which become so by the assistance of fire; but the fire here spoken of is not great enough to dissolve their constituent parts, but only such as may affect the external parts of their texture, and that but gently; so that the process here mentioned is only drying or roasting. For it is not the watery or the saline parts in bodies which are torried, but the oleaginous, with which many vegetables, and most animals abound. The white flesh of animals, such as that of chickens, become a phosphorus by roasting, as well as the tendons; and whatever parts of animals become glutinous by boiling, such as carpenters' glue, isinglass, &c. to these may be added cheefe. Bones, though they imbibe light without any preparation, have that property in a much greater degree when burnt, and their luminous appearance is much more lively. But roasting has not this effect upon feathers, hoofs, horns, and only in a small degree on whites of eggs, though the yolk when dry easily became a phosphorus.

The same operation which produces several phosphori from the animal kingdom, gives also several from the vegetable. Thus, by gently roasting ginseng, as myrrh, gum tragacanth; and others, they appear luminous, though dif-

ferent in degrees; and this light is clear in proportion to the gentle evaporation of the aqueous parts. By this treatment nuts of every kind, pulse, corn, coffee-berries, meal, bread, and wafers, also become phosphori. Turpentine, amber, and some resins, require more fire before they imbibe light; so that you must divest them of their acid, and their light ethereal oil, to make them appear luminous. But here great care must be taken that they boil no longer than from being white they turn yellow; for, if you proceed longer, your labour is lost. Those phosphori produced by torrefaction soon lose their power, which, perhaps, neither time, nor a thorough dissolution of their parts, can deprive the natural ones of. In general, as long as the phosphori gained by torrefaction preserve their power, their light is more sharp and striking, but the natural more weak. Those that are gained by calcination, and Baldwin's phosphorus, seem to possess both the striking light of those gained by torrefaction, and the weaker light of the natural phosphori: the last they preserve a long time, but the former is lost, by degrees, much sooner. The well calcined ashes of plants, or rather their terrestrial parts, remaining after the solution of their fixed salts by washing, and neutral salts, continue phosphori after many years: so that, as far as we can judge, the luminary power which is gained by calcination, though not so intense, continues perpetual; whereas, that gained by torrefaction always decreases, and, in a very little while, is no longer visible. Some, even by this method, continue to imbibe light much longer than others. Gum arabic, which continues longest, lasts six days; bread not one, and coffee only a few minutes. However, at any time, by a fresh torrefaction, you may recover these languid phosphori; in which property they have great likeness to the Bolognian stone, and other phosphori prepared by art.

Almost all bodies, by a proper treatment, have that power of shining in the dark, which, at first, was supposed to be the property of one, and afterward only of a few. How this is brought about is not easy to solve. If we suppose, with some, that the light from a luminous body enters and abides in the phosphori; we shall find somewhat new to admire in light itself. It is no new opinion, that this fluid consists of very fine particles, which are continually darted forth from a luminous body in all directions, with a very great velocity; but it has by nobody been laid down hitherto, that these particles are not dissolved by the violence of their agitation, nor dispersed, nor immediately cease to exist; but subsist still, and adhere to what bodies come in their way, as heat does. If, therefore, the particles of light are not dissolved as soon as they are emitted from a radiant body, but continue some time, what else is required but that we allow its atmosphere to every lucid appearance? If the phosphori shine only with a borrowed light, but not with their own, and that only when put in motion, and fired by the rays of a shining body, which some experiments seem to confirm, then other new doctrines will arise. There must be then a hidden, a secret principle in bodies, to be lighted up by this most subtle fire. There will be in the universe a certain perpetual fire from these phosphori; the matter of which, though constantly dissipated by burning, does not waste enough to be obvious to our senses. See Phil. Trans. N 478. in vol. xlv. art. 17. p. 83. and Beccarii Com. p. 52. 91, &c. See LIGHT, LIGHT from Diamonds, and Bolognian PHOSPHORUS, *infra*.

Of artificial phosphori there are three principal kinds: the first *burning*, which consumes every combustible it touches; the other two have no sensible heat; and are called

PHOSPHORUS.

called the *Bononian* and *Hermetic* phosphorus, to which class others of a similar kind may be reduced.

PHOSPHORUS, Burning, in *Chemistry*, is a simple inflammable substance.

The discovery of this phosphorus was first made in 1677, by one Brandt, a citizen of Hamburgh, in his researches for the philosopher's stone. Brandt communicated the secret to one Kraaft, of Dresden, but withheld it from Kunckel; upon which this chemist, knowing that urine was the substance employed, succeeded in his attempts of making phosphorus; accordingly, this phosphorus is commonly called *Kunckel's* phosphorus, after his name. A similar phosphorus was also made by Mr. Boyle, after having seen a piece of it in the hands of Kraaft, who brought it to London in 1679, in order to shew it to the king and queen of England; having been only informed that this phosphorus was produced from some matter belonging to the human body. Kraaft, indeed, told Stahl, that he had communicated the process for making it to Mr. Boyle; but this is such an imputation on the integrity and honour of our English philosopher, as can by no means be admitted on the testimony of a man, who had been treacherous to Kunckel, who traded in the secret of making phosphorus, and after selling it to many persons, published the process for making it in the *Mercurie Galant*, for June 1683. Kunckel, and a German chemist called Godfreid Hantkowitz, to whom Boyle communicated the method of preparing it, were the only persons who made it in any considerable quantities.

M. Hellot, in his *Memoir* upon this subject, *Ac. Paris*, 1737, enumerates all the processes for making it, that were in use soon after the discovery of it; viz. that published by Mr. Boyle in 1680, in the *Phil. Transf.* N^o 196. (see *Phil. Transf. Abridg.* vol. iii. p. 346.); that of Kraaft; that of Brandt, in a collection of experiments and observations of Dr. Hooke, published by Dr. Derham in 1726; that of M. Homberg, in the *Ancient Memoirs* of the Academy, in 1692; and those found in the works of several chemists, particularly of Theickmeyer, Hoffmann, and Niewentyt. However, the operation continued in a great degree a secret till the year 1737, when a stranger came into France, and obtained a reward from the ministry for communicating his process, which was executed by Messrs. Hellot, Du Fay, Geoffroy, and Duhamel. Since the publication of M. Hellot's *Memoir*, the operation has been no longer a secret; though seldom executed, because it was rather curious than useful, and both troublesome and expensive.

The solid phosphorus was formerly prepared from urine in the following manner. Evaporate a good quantity of urine of beer-drinkers to the consistence of honey; cover it up in an earthen vessel, and set it three or four months in a cellar to ferment and putrefy. Mix two parts of sand, or powder of pot-sherds, with one part of this urine, and put it into a retort, fitted to a long-necked receiver, with two or three quarts of water in it. Distil it in a naked fire, in a reverberatory furnace; at first gently; after two hours, augment the fire gradually, till all the black fetid oil be drawn off. Raise the fire to the highest degree; upon which white clouds will come into the receiver, and fix, by little and little, on one side, in form of a yellowish skin; and another part will precipitate to the bottom in powder. Keep the fire thus violent for three hours, till no more fumes arise. Let all cool, and unloose the vessels; and, throwing more water into the receiver, shake all well about, to loosen what sticks to the sides. Pour the whole into a glass vessel, to settle.

The volatile salt will now dissolve in the water, and the

phosphorus and oil will sink to the bottom; then pour off the water, and gathering the remaining part together, put it into a glass vessel, with a little fresh water, and digest it in a sand-heat, stirring it from time to time with a wooden spatula.

By this means, the phosphorus will separate from the oil, and sink to the bottom: pour off the oil, and make up the phosphorus, while hot, into sticks for use.

Boerhaave gives us other ways of preparing phosphorus. Recent urine, he observes, digested three or four days in a tall glass, with a heat no greater than that of a healthy man, grows ruddy, fetid, and cadaverous; this digested urine, being put to distil in a retort, yields a clear, fetid liquor, then a yellow volatile salt, which evaporated to the consistence of a soap, and mixed with four times its weight of dry sand, and the distillation continued in a covered retort, there successively comes over, by greater and greater degrees of fire, a fetid brown oil, blueish fumes, and, finally, a gross shining matter, which sinks in water, and is the solid phosphorus.

To make it more easily, and to the best advantage, it may be proper to take a sufficient quantity of human urine, afforded by a person not much given to drink wine, and exhale it away in an open vessel to a rob, or the consistence of honey; then set it to putrefy for half a year, and, upon distillation, it will afford a large proportion of salt, after which, if six times its own quantity of sand, or brick dust, be added to the remainder, and the distillation be continued, as in the case last mentioned, the phosphorus will fall into the water. Or it may commodiously be prepared, by suffering the rob of urine to digest for two years in an open vessel in the open air; during which time, a slimy, feculent, unctuous, earthy matter, will fall to the bottom; which, being frequently washed with pure water, wherein it will not dissolve, will leave a white matter behind it, neither of an alkaline, acid, saline, or terrestrial, nor scarcely of an unctuous nature: and this is of itself a proper matter for the making of phosphorus by distillation with sand.

In order to preparing the phosphorus, and indeed most of the other preparations of urine, the first step is to reduce that liquor to the consistence of a rob or thick extract; those who have worked on this subject sufficiently know how abominably nauseous and disagreeable a task this is. The operator alone is not the person who is almost poisoned by it, but the whole neighbourhood is affected; and it is well known, that our Godfrey, who used to prepare large quantities of this substance, was always obliged to keep a house in the fields to perform this part of the process in.

There is an easy and excellent method proposed by Stahl for the performing of this troublesome business, by means of condensation by cold or freezing. There needs no more than to expose the proper quantity of urine to some frosty nights in winter; or at any time of the year to our ice-houses, or other places where ice is preserved all the year round. The frost will, in this case, affect a large part of the urine, but not the whole; and the liquid part being separated from the solid ice, it will be found that the watery parts alone have suffered the freezing, and that all the unctuous and saline ones are left behind in the unfrozen part, which is, by repeated freezings of its yet remaining aqueous parts, at length reduced to that sort of rob which is required for all the purposes of distillation, and that without any trouble or offensiveness, either to the operator or any body else. The power of condensation by freezing in this manner, extends to wine, vinegar, and all fermented liquors;

PHOSPHORUS.

liquors; but it operates differently on the several different ones, and is to be regulated according to their natures. The natural cold of our climate is seldom too great for any of the liquors we desire to condense; that is, it is never so great as to condense the whole into ice. It often is not sufficiently great to condense the aqueous part, even after ever so many repetitions. In this case, it may be proper to bring in the use of the common freezing mixtures, made with ice, or snow and salt. To suit the artificial degree of cold, in these cases, requires care and experience, and is almost as nice a point as the suiting of the degrees of heat in the operations of chemistry.

In 1743, Mr. Margraaf published, in the Memoirs of the Academy at Berlin, a new and excellent process for obtaining more easily and expeditiously, and at less expence than had hitherto been done, a considerable quantity of phosphorus. In his process, a kind of plumbum corneum is previously prepared, by distilling a mixture of four pounds of minium with two pounds of powdered sal ammoniac; the residuum after the distillation, or the plumbum corneum, is to be mixed with nine or ten pounds of extract of putrefied urine, boiled to the consistence of honey. This mixture is to be made slowly in an iron cauldron set upon the fire, and by frequently stirring the contents. Half a pound of powdered charcoal is then to be added, and evaporation is to be continued till the whole is reduced into a black powder, which is to be put into a retort, in order to extract from it, by a moderate and gradual heat, all the volatile products of urine, that is, volatile alkali, fetid oil, and an ammoniacal matter which adheres to the neck of the retort. In this distillation the heat is only to be raised so as to make the matter red-hot. After the distillation a black and friable residuum is left, from which the phosphorus is to be extracted by a second distillation, and a stronger heat. Before it is exposed to another distillation it may be tried by throwing some of it upon hot coals. If the matter has been well prepared, a smell of garlic exhales from it, and a blue phosphorical flame is seen undulating along the surface of the hot coals. This matter is to be put into a good earthen retort, capable of sustaining a violent fire, and which may be secured with a covering of clay and hair. Three quarters of the retort are to be filled with the matter which is to yield the phosphorus. It is to be placed in the common furnace for distillation with a retort; excepting that instead of being terminated by an ordinary reverberatory or dome, this ought to be terminated by the upper piece of an air-furnace, to which a tube is to be applied, the diameter of which ought to be from four to six inches, according to the size of the furnace, and the height from eight to nine feet. This apparatus, which Mr. Beaumé uses, is necessary for raising a sufficient heat, and for the convenience of throwing in a sufficient quantity of fuel through the door of the upper piece of the furnace. The retort ought to be well luted to a receiver of moderate size, pierced with a small hole, and half full of water. For this purpose ordinary fat lute may be bound on with strips of linen, dipped in a lute prepared with lime and whites of eggs. The hole in the furnace through which the neck of the retort passes ought to be well stopped with furnace-earth. Lastly, a small wall of bricks is raised betwixt the furnace and the receiver, to guard this vessel against heat as much as is possible.

All these preparations being made the evening before the distillation is to be performed, we are then capable of proceeding to this operation, which is very easy. The retort is to be heated by slow degrees during an hour and a half; and then the heat is to be increased till the retort be red-

hot, and the phosphorus begin to pass in luminous vapours; when the retort is almost of a white-red heat, the phosphorus passes in drops, which fall and congeal in the water at the bottom of the receiver. This degree of heat is continued till no more passes into the receiver. When a retort contains eight pints or more, this operation continues about five hours.

Mr. Margraaf's apparatus is somewhat different from that above described. He divides the whole quantity of matter from which the phosphorus is to be obtained into six small retorts, which he places in a furnace that he describes. The advantage of this division is, that if any accident happens to one retort, the whole matter is not lost; and as the retorts are smaller, a less heat is required. If, indeed, much phosphorus was to be made, this practice would be safe and excellent; but Macquer affirms, that the method above described of Mr. Beaumé is very convenient when a large quantity of phosphorus is not wanted, and that he has never seen it fail.

Phosphorus does not pass pure in this distillation, but is blackened by soot or coal, which it carries along with it: it may be easily purified, and rendered white and fine by a second distillation or rectification. This rectification is made in a small glass retort, to which is adjusted a small receiver half full of water. A very gentle heat is sufficient, because phosphorus once formed is very volatile: and as the fuliginous matters with which it is soiled were raised merely by the violence of the heat, they remain at the bottom of the retort in this distillation, and the phosphorus passes very pure.

The phosphorus is then usually divided into small cylindrical rolls, for the conveniency of using it. This is done by putting it in glass tubes immersed in warm water. This very gentle heat is sufficient to liquefy the phosphorus, which is almost as fusible as suet. It takes the form of the glass tubes, from which it may be taken out when it is cold and hardened. That it may be more easily taken out of the tubes, these must be somewhat of the form of frustums of cones. All these operations ought to be made under water, to prevent the inflammation of the phosphorus.

Phosphorus is now usually procured by the following process. Calcine a quantity of bones till the whole of their inflammable matter is consumed, which will be indicated by their whiteness. After they are reduced to a fine powder, let 100 parts, by weight, be mixed with 500 parts of water, in a vessel of stone ware, or any other which sulphuric acid will not act upon. To the above mixture add, by degrees, 40 parts of sulphuric acid, constantly stirring the mixture with a stick or a glass rod. After the effervescence has subsided, let the mixture stand for a day or two, then decant off the clear liquor, which is to be preserved. Let the residuum be agitated with a quantity of fresh water, and thrown upon a filtre, adding the clear liquor which runs through to that decanted in the first instance. Let more water be poured upon the filtre till it comes through tasteless. This being added to the last, the whole will contain a super-phosphat of lime, with great excess of acid. In order to separate the phosphoric acid from the lime, the nitrat of lead is to be added. Phosphat of lead precipitates in the state of white powder, while the lime is dissolved in the nitric acid. The phosphat of lead being very ponderous, may be separated by decantation and repeated washing. When the powder is dried, mix it with one-eighth its weight of charcoal powder, and put it into an earthen retort. The common earthen retorts are seldom fitted for this process, being very liable to crack. The clay of which they are formed should be mixed with coarsely powdered

PHOSPHORUS.

cibles, to render the texture of the substance when baked more open. The outside must be coated with white lead and flint, to form a glazing during the distillation of the phosphorus. Without this precaution the vapour of the phosphorus would escape through the pores of the vessel. The retort, with its contents, must be placed in an air-furnace, with a slit in the side to admit the neck of the retort. The fuel should be well burnt coaks, and the fire raised very gradually. The neck of the retort should be luted to an adopter, which is fitted to a glass receiver, previously filled with azotic gas. A small tube should proceed from another opening in the receiver, terminating in a pneumatic trough. This serves to carry off the elastic fluids which are disengaged in the process. During the first stage of the process carbonic acid is disengaged, which is afforded by the carbon combining with the oxygen of the phosphoric acid and the oxyd of lead. The charcoal always contains a portion of moisture, which is decomposed by the carbon. In the last stage of the process, when the phosphorus rises in the elastic form, a portion of it combines with the hydrogen of the water, forming phosphoretted hydrogen gas, which takes fire when it comes in contact with oxygen of the atmosphere. This spontaneous inflammation of the escaping bubbles, is a certain sign that the phosphorus is coming over. It is seen running down the adopter into the receiver, which contains a small portion of water for it to drop into. The mass which drops into the water is generally of a brownish, and sometimes a darker colour, and consists of phosphorus, containing some carbon, and is otherwise impure. When the apparatus is quite cold, it may be taken out, and placed in a glass funnel provided with a long cylindrical neck, about one-fourth of an inch in diameter, closed at one end with a cork. It is first filled with cold water, so as to cover the phosphorus. The whole is now immersed into hot water, which melts the phosphorus which is caused to occupy the interior of the tube, assuming a pale yellow colour, while that in the top part of the tube is of a darker colour, and contains the impurities. The pure part is broken into pieces, in which state it is sold. If the phosphorus after distillation be very impure, it should be distilled a second time from a glass retort, observing the same precautions in the receiver as in the first process. After this it may be strained through chamois leather under hot water.

The phosphat of lead may also be procured by adding nitrat of lead to urine. The latter substance contains a quantity of the phosphats of soda and ammonia, each of which give up their acid to the lead, forming phosphat of lead, which falls to the bottom of the vessel in the state of an insoluble white powder. This is doubtless the cheapest way of getting phosphorus.

Stahl supposed phosphorus to be a compound of muriatic acid with phlogiston; but it was afterwards proved by the researches of Margraaf, that muriatic acid could not be produced by burning phosphorus, nor could he succeed in forming phosphorus by treating muriatic acid with inflammable bodies. He found in the course of his experiments, what has since led to the overthrow of the phlogistic doctrine. The phosphorus gained weight by burning, and he called the substance resulting from the combustion phosphoric acid. Lavoisier, in a satisfactory manner, confirmed the facts of the above chemist, by burning phosphorus in oxygen gas. The diminution of the oxygen he found just equal to the increase of weight in the phosphorus after burning. Hence it was established, that phosphoric acid was a compound of phosphorus and oxygen.

Phosphorus, when perfectly pure, is of a pale yellow colour, having some resemblance to white wax. Like the

latter substance it softens by heat, and is so ductile as to be cut with a knife.

It is called "phosphorus fulgurans" from its corruscations; and "phosphorus smaragdinus," because its light is frequently green or blue, especially in places that are not very dark.

It is also called "solid phosphorus," from its consistence. It dissolves in all kinds of distilled oils; and, in that state, is called the "liquid phosphorus."

It may be ground in all kinds of fat pomatums; in which case it makes a luminous unguent.

So that the phosphorus fulgurans, smaragdinus, solid and liquid phosphorus, and luminous unguent, are all the same preparation, under different circumstances. See *FULGURATING Phosphorus*.

The specific gravity of phosphorus is about 1.77; the fusing point is 90° Fahr.; and it assumes the form of vapour at a little short of 600°.

When phosphorus is heated to 148 in the open air, it takes fire and burns with great brilliancy, owing to the rapidity with which it combines with oxygen. Very dense white fumes are produced, so as ultimately to nearly obscure the flame. If the combustion be made in a vessel, the fumes adhere to its sides, and become liquid, by attracting moisture from the atmosphere. A portion of red matter is left after the burning has ceased, which is probably a compound of phosphorus and carbon. The liquid which is formed upon the sides of the vessel has an acid taste, and consists of phosphoric acid, water, and probably a small quantity of phosphorus which has escaped combustion. When phosphorus is burnt in pure oxygen, the light produced is of such dazzling splendour as to give pain to the eyes. The combustion is by this means complete, and if the oxygen is in sufficient quantity, the whole is converted into phosphoric acid.

Lavoisier found that 100 grains of phosphorus took up 154 grains of oxygen, supposing the atom of oxygen to be 7, hydrogen being 1, agreeably to the numbers of Dalton. And considering the phosphoric acid as an atom of phosphorus

with two atoms of oxygen, we have $\frac{154}{100} = \frac{14}{9.1}$. Dalton

has fixed the atom of phosphorus at 9. From these data the atom of phosphoric acid will be $9 + 2 \times 7 = 23$.

When phosphorus is exposed to the air in small bits, it gives out a white smoke for some time, and is ultimately changed into a clear vivid oily liquid, which has an acid taste. In this process it combines slowly with oxygen, and consists of one atom of phosphorus with one of oxygen, or $9 + 7 = 16$. When phosphorus is made to undergo slight combustion, by melting it over the interior of a phial, with the presence of small quantities of air, the phosphorus assumes a reddish colour. By this change it is found to take fire with much greater facility, so much so that this process is resorted to in the construction of the common fire bottles.

From this and other facts it is probable that an oxyd of phosphorus exists with less oxygen than is contained in phosphorous acid. It doubtless is constituted by 2 atoms of phosphorus to 1 of oxygen, or $2 \times 9 + 7 = 25$. See *PHOSPHOROUS and PHOSPHORIC Acids*.

The action of the acids upon phosphorus is treated under the respective acids, but what has been omitted under *OXYMURIATIC Acid*, we shall introduce here.

The muriatic acid does not act upon phosphorus when the acid is in the gaseous form, but when presented in combination with some other bodies, it forms very curious combinations, which have been little noticed. We are indebted

PHOSPHORUS.

indebted to sir Humphry Davy for our knowledge of these facts.

When phosphorus is immersed in oxymuriatic acid gas, it burns with a pale flame, producing a white substance, which adheres to the sides of the vessel. The above chemist found that one grain absorbed nine cubic inches of the gas, and hence concludes that 1 of phosphorus combines with 6.8 of oxymuriatic acid, or, agreeably to the nomenclature of this philosopher, who considers the latter a simple body, *chlorine*. The number he gives to represent one proportion of chlorine is 67, that of oxygen being 15 and phosphorus 20; so that he concludes the compound formed by burning phosphorus in chlorine gas to consist of two proportions of chlorine equal 134, to one proportion of phosphorus equal to 20, or $134 + 20 = 154$, the number representing the compound. To this substance he has given the name of phosphorana. The advocates of the old hypothesis consider this compound as constituted by two atoms of muriatic acid, free from water, united to one atom of phosphoric acid, and agreeably to the common nomenclature it will be called a supermuriat of phosphorus. Dalton's number for muriatic acid is 22, for oxygen 7, and for phosphorus 9. Hence this substance will be constituted by $2 \times 22 + 2 \times 7 + 9$, or 58 oxymuriatic acid to 9 of phosphorus, but in fact 44 muriatic acid to 23 phosphoric acid.

The compound in question is described by its discoverer as being a snowy white substance. It is volatile at a temperature less than that of boiling water. It is capable of being fused under pressure, and then crystallizes in the shape of prisms which are transparent.

He states that "it acts violently upon water, which it decomposes." Its phosphorus combines with the oxygen, producing phosphoric acid, and its chlorine with the hydrogen, forming muriatic acid. The advocates for the old opinion equally well explained the action of water upon this substance, by supposing the same quantity of water to combine with the muriatic acid, which sir Humphry would state to be decomposed.

Another compound of this kind has been discovered by the same chemist, by distilling phosphorus through the powder of corrosive sublimate in a glass tube. A limpid fluid is obtained, which he states to be a compound of one proportion of chlorine with one proportion of phosphorus, or $67 + 20 = 87$. The properties of this compound are stated by sir Humphry as follows: it emits and fumes when exposed to the air, decomposing the aqueous vapour, and is converted into acid in the air without inflammation. In its pure state it does not redden dry litmus paper. The vapour from it burns in the flame of a candle. When poured into water, it is converted into muriatic and phosphorous acid, the hydrogen combining with the chlorine to form muriatic acid, and the oxygen with phosphorus forming phosphorous acid. This solution, being evaporated to the consistence of syrup, affords a very pure phosphorous acid combined with water, the muriatic acid having escaped. It becomes solid on cooling.

Sir H. Davy has called the above compound phosphorana.

By those of the common opinion, this substance is considered as a compound of pure muriatic acid and phosphorous acid. The phosphorus, on passing through the superoxymuriat of mercury, took an atom of phosphorus from the mercury forming phosphorous acid, which, combining with an atom of muriatic acid, formed the compound in question, leaving behind an atom of muriat of mercury (calomel), which consists of an atom of muriatic acid, with an atom of the first oxyd of mercury. By Dalton's numbers this substance is constituted by one atom of muriatic acid, 22

added to one of phosphorous acid, equal to $9 + 7$ or 16, the whole being equal to $22 + 16 = 38$. All the phenomena stated above, which have been explained by sir Humphry's hypothesis, will be equally well explained by the old theory. The above ingenious chemist has pointed out a third compound of chlorine with phosphorus, which he supposes to consist of one proportion of chlorine with two of phosphorus, or $67 + 2 \times 20 = 107$. This, by the old doctrine, would be considered as composed of 1 of muriatic acid, 22 to 2 of phosphoric oxyd, equal 32, the whole being 52.

This substance was first obtained by Guy Lussac and Thénard, by distilling phosphorus and calomel. If its constitution be as above stated, 9 of phosphorus should be distilled with 196 of calomel.

Phosphorus combines with hydrogen, forming a gaseous compound called by some phosphoretted hydrogen, and by others more properly phosphoret of hydrogen. Several circumstances shew the affinity between phosphorus and hydrogen to be very slight, particularly its liability to be decomposed even by agitation with water. The following is the process recommended by Dalton for procuring it. To two ounces of dry hydrat of lime, or lime which has just taken as much water as is required to slack it, add 50 grains of phosphorus in small bits. Let these be put into a glass retort, which has been previously filled with nitrogen gas. Without the latter precaution the presence of oxygen would decompose the gas intended to be obtained. Let the neck of the retort be connected with an hydromuriatic trough, and apply the heat of a lamp, which brings over the gas. The lime is here more than is necessary, which is no inconvenience. The absolute quantities which are engaged in the process are, 1 atom of hydrat of lime = $8 + 24$, and 2 atoms of phosphorus = $2 \times 9 = 18$. The water of the hydrat of lime is decomposed. The oxygen combines with one atom of phosphorus, forming phosphorous acid, which afterwards combines with the lime. The hydrogen combines with the other atom of phosphorus, forming phosphoret of hydrogen, which comes over in the form of gas. In this state it takes fire spontaneously in the open air, or in contact with oxygen. The phosphorus is easily separated by the electric spark, and even by standing over water, leaving the hydrogen pure, and occupying the original volume of the gas. This latter effect taking place partially, has given rise to the opinion of phosphorus combining with hydrogen in different proportions. We can hence explain the assertion made by sir H. Davy, in which he says he has obtained phosphoretted hydrogen gases of different specific gravities, from 4 to 7; hydrogen being 1.

The composition of this gas is easily inferred from its specific gravity, which Dalton states to be 10.5, hydrogen being 1. Hence if 1 of hydrogen takes up 9.5 of phosphorus without any change of volume, it will make the specific gravity as above. By theory, 9 of phosphorus should combine with 1 of hydrogen, when 1 atom of the former combines with 1 of the latter. We may hence conclude that an atom of this gas in a state of purity is $1 + 9 = 10$.

To confirm this, Mr. Dalton found that 1 measure of this gas to 1.5 oxygen produced phosphoric acid; and 1 measure to 1 produces phosphorous acid. We are indebted to sir Humphry Davy for the discovery of a new compound of phosphorus and hydrogen, which he obtained by exposing the solid hydrat of phosphorous acid to heat in a retort. An elastic fluid is produced, having a less disagreeable smell than the phosphoret of hydrogen, already described. It does not, like the latter, explode spontaneously. When heated to 300° Fahrenheit with oxygen, it detonates with violence.

PHOSPHORUS.

violence. It also explodes in oxymuriatic gas with a white flame. This chemist supposes its specific gravity to be about 12, hydrogen being 1.

When heated in potassium, its volume is doubled, and the gas produced is pure hydrogen. When sulphur is sublimed in it, the volume is doubled, and sulphuretted hydrogen gas produced.

He found that 3 in volume of this gas took up more than 5 of oxygen. He concludes its composition to be nearly 2 of hydrogen to 10 of phosphorus, by weight. According to Dalton's numbers it will consist of an atom of phosphorus to 2 of hydrogen, or $9 + 2 = 11$. If its volume be doubled by taking away its phosphorus, which is the case in the experiment with potassium, its specific gravity will be increased by 1 compressed into $\frac{1}{2}$, which will give a specific gravity equal to 2: this added to 9, the weight of the phosphorus, will give $9 + 2 = 11$, which is very near to Sir Humphry's experiment. In the experiment where it combines with the sublimed sulphur, the volume is doubled, and two atoms of sulphuretted hydrogen are formed, one of which being equal to the original volume, will make the specific gravity of this gas equal to that of sulphuretted hydrogen, which is about 14, hydrogen being 1. The mean of these will be $\frac{11 + 14}{2} = 12.5$, which comes very near to Sir Humphry's statement of the specific gravity, and strongly confirms the rest of the facts relative to it.

The oxygen required for its total absorption will be 28 to 11 by weight, and $\frac{28}{11} \times \frac{12}{14} = \frac{24}{11}$, or 2 to 1 by measure nearly. This is obtained by multiplying their ratios of weight by the inverted ratio of their specific gravities.

Phosphorus combines with sulphur by melting them together in a glass tube, from which oxygen is excluded. The compound is more fusible than either of the elements. Sir Humphry Davy found that a compound of these bodies in the proportion of 3 of sulphur to 4 of phosphorus, is fusible at 40° Fahrenheit. When solid, its colour was of a yellowish-white. These bodies, like all others, must produce most complete compounds in certain definite proportions dependent on the ratio of the weight of their ultimate atoms. Atom to atom, their proportions will be 9 to 13. The compound above alluded to will be 2 atoms of phosphorus to 1 of sulphur, or $18 + 13 = 31$. The most remarkable properties possessed by these compounds are their increased fusibility, and their taking fire at a lower temperature than phosphorus. This latter property has been taken advantage of in making the common fire-bottles. Their proportions for this purpose are generally about 2 phosphorus and 1 sulphur. This is nearly 3 atoms of phosphorus to 1 of sulphur, which would be 3×9 to $13 = 27$ to 13.

Dr. Priestley has made many experiments with phosphorus, in different kinds of air; and has found, that it smoked and gave light in the acid air, just as it would have done in common air confined, without being sensibly wasted for twelve hours, and with a very inconsiderable diminution of the bulk of the air; in alkaline air it gave no light and made no lasting change in its dimensions; in nitrous air, it gave no light, nor did it lessen its power by diminishing common air, and the phosphorus remained unchanged; and after having remained a day and two nights in vitriolic acid air, it produced no sensible effect, and gave no light.

Dr. Fordyce has suggested the following easy method of reducing phosphorus to powder: take phosphorus of urine two drachms; put it into a four-ounce phial; pour upon it three ounces of water; heat it gently by immersion in warm water, till the phosphorus melts; shut the phial with a cork;

take it out of the water, and shake it briskly till it be cold; and the phosphorus will be found in powder. A receiver may be lined with this powder by adding a very small quantity of water to it, and then making the powder to adhere to its internal surface, by gently inclining and turning the receiver round. Macquer's Chem. Dict. art. *Phosphorus*, and Priestley's Experiments and Observations on Air, &c. Phil. Transf. vol. lxi. part ii. p. 504, &c.

PHOSPHORUS, Properties of Solid. 1. With this phosphorus one may write on paper as with a pencil, and the letters will appear like flame in the dark; yet, in the light, nothing will appear but a dim smoke. This is occasioned by the oxygen of the atmosphere combining slowly with the phosphorus.

If the letters written with this phosphorus are warmed by the fire, they presently become dark lines, which continue upon the paper like ink.

2. A little piece, rubbed between two papers, takes fire instantaneously, and if care be not taken in the management of it, there is danger of burning the fingers, the phosphorus being exceedingly inflammable.

3. Its burning is very vehement, and penetrates deeper into the flesh than common fire; and it is very difficult to be extinguished.

Dr. Slare, in order to determine whether air contains the pabulum of flame, as some have supposed, placed a large piece of phosphorus in a receiver; but upon exhausting it, he found that it became more luminous, and that upon admitting the air it returned to its former state. This property was also ascertained by several experiments of Mr. Haukbee.

M. Cassini happening to press a piece in a cloth between his fingers, the cloth immediately took fire; he endeavoured to put it out with his foot; but his shoe caught the flame, and he was obliged to extinguish it with a brass ruler, which cast forth rays in the dark for two months after.

The solid phosphorus ceases to shine and never spoils, provided it be kept in a phial full of water; but if any part of it emerge, it will shine, though the glass be hermetically sealed; and will continue shining in a large glass without water for several days, with very little diminution of its light or weight; and even when immersed in water, it will sometimes make very bright and vigorous corrufcations in the air; that in form of an unguent, does not keep so well; and the liquid phosphorus worst of all.

The liquid phosphorus is best made by digesting in horse-dung, a little bit, or some scrapings of the solid kind, for two days, in oil or essence of cloves, oil of turpentine, or the like. After the dissolution, the oil will be so impregnated with it, that, upon opening the bottle, the matter will appear on a flame.

PHOSPHORUS, Experiments with Liquid. By washing the face, hands, or the like, with liquid phosphorus, Dr. Slare tells us they will be made to shine very considerably in the dark, and the lustre thereof will be communicated to adjacent objects, yet without any offence to the skin.

As soon as the candle is brought in, the shining disappears, and no change is perceivable.

This phosphorus emits frequent flashes like lightning, even when close stopped, especially in warm water. Hence Mr. Boyle takes occasion to draw a parallel between lightning and phosphorus. Phil. Transf. Abr. vol. iii. p. 348, &c. Haukbee's Physico Mech. Exper. p. 122. In some cases animal sweat, which is similar to urine, has been observed to be phosphoraceous, without any preparation. An instance of this kind is related of a person who used to eat great quantities of salt, and who was a little subject to the gout, after sweating with violent exercise. Stripping himself in the

PHOSPHORUS.

the dark, his shirt seemed to be on fire, and a urinous smell was perceived, similar to that which issues from cabbage much falted and strongly fermenting. Act. Cæsariensis, vol. v. p. 334.

PHOSPHORUS, Bolognian, or Bononian. The second kind of artificial phosphorus, is a preparation of stone called the Bononian stone, from Bologna, a city in Italy, near which it is found.

The first who undertook to make this stone luminous, was a chemist of that city, called Vincenzo Casciarolo. Poterus, Licetus, &c. have described the process; but mistakenly. M. Homberg, who made a journey to Italy, expressly to learn the preparation, first communicated the same to M. Lemery, who published it in the seventh edition of his chemistry. (See *BONONIAN Stone*.) Under that article, the reader will find some account of the discovery of this stone, and of the method of preparing it. We shall here subjoin some farther particulars on this subject, chiefly extracted from the dissertations of M. Margraaf. The Bolognian stone, he says, is soft, friable, heavy, crystallized, and incapable of effervescing with acids, before it has been calcined in contact with fuel, and with a free access of air. These qualities have induced him to class it among the heavy fusible spars, which, by a preparation similar to that for the Bolognian stone, are rendered phosphoric. After analysing these substances, he concludes that all contain a vitriolic acid, united to an alkaline or calcareous earth. In order to render these stones phosphoric, such of them ought to be chosen as are the clearest, but crystallized, most friable, most heavy, which exfoliate when broken, and which contain no heterogeneous parts. They are to be made red-hot in a crucible, and reduced to a very fine powder in a glass mortar, or upon a porphyry, and not in a copper mortar, which will obstruct the success of the operation. The powder thus obtained, is to be formed into a paste with gum tragacanth, and divided into cakes as thin as a knife. These are to be dried by a gradual heat. An ordinary reverberatory furnace is to be filled to three quarters of its height with charcoal, and the fire to be kindled; upon this charcoal the flat surfaces of the cakes are to rest; and more charcoal is to be placed above them, so as to fill the furnace, which is then to be covered with its dome, the tube remaining open: all the coal is to be consumed, and the furnace left to cool. The cakes are then calcined, and are to be cleaned from the ashes by blowing upon them with bellows. He farther observes, that after this calcination through the coals, if the stones be exposed to a stronger calcination during a full half hour under a muffle, their phosphoric quality will be rendered stronger. Ac. Berlin, 1749, and 1750.

This phosphorus has not any sensible heat, and only becomes luminous after being exposed to the sun, or the daylight; in which state it resembles a burning coal, and preserves its light five or six minutes in the dark, especially if the person observing it has been some time in the dark, or has shut his eyes, that the pupils may be sufficiently expanded; during which time the light gradually dwindles; and, to recover the shining, it must be exposed afresh to the light.

PHOSPHORUS, the Hermetic, or Phosphorus Balduini, which makes the third kind, and properly belonging to the same class with the former, is a preparation of English chalk, with aquafortis, or spirit of nitre, by the fire. See *BALDWIN'S Phosphorus*.

This makes a body considerably softer than the Bolognian stone; but it has all the qualities of it. It has its name from its inventor Baldwin, a German chemist, called *Hermes*, in the society of the *Naturæ Curiosorum*; whence

its other name *Hermetic*. It was discovered a little before the year 1677.

This phosphorus of Baldwin is exactly similar to those made with Bolognian stone and phosphoric spars, differing only in the kind of acid which it contains. It is evidently a nitre with a calcareous basis, and in calcination acquires its phlogiston from the nitrous acid, the chalk also containing some of this inflammable principle. It is observed, however, that this is not so good a phosphorus as the Bolognian; it is not so luminous, it does not retain the light so long, it soon loses its virtue, and never recovers it again. Acad. Par. 1693, p. 271.

The process for making this phosphorus, though Baldwin gave no direction for it, nor so much as mentioned the materials, was communicated to the Royal Society, in 1679, by Dr. Slare, and published by Grew, in his *Mus. Reg. Soc.* p. 353; and is as follows: Take good firm chalk, ignite it in a crucible, and then powder it; put into a pint, or half a pint of strong spirit of nitre, *cochlearim*, as much of the powdered chalk as will serve well to satiate it, *i. e.* till it becomes sweetish, and makes no effervescence upon the injection of the chalk. Then dilute this liquor with fair water, filtre it through a paper, and so evaporate it in a large glass, or glazed vessel, or good Hessian crucible, to a dry salt. The preparation may be performed in four hours.

To this class we may also refer some other phosphori, enumerated in the sequel of this article. As the

PHOSPHORUS, Ammoniacal, composed of sal ammoniac and lime, which Mr. Homberg first discovered.

The method of preparing it is this: Take one part of sal ammoniac in powder, and two parts of lime extinguished by lying in the air: mix them exactly together and fill a crucible with the mixture; set it in a small melting heat. As soon as the crucible grows red-hot, the matter in it will melt, and it must be stirred with an iron rod, lest it swell over the edges of the crucible: as soon as the whole is melted, pour it into a copper basin; it will appear of a greyish colour and vitrified, and if it be struck upon with any hard body, there will be seen a fire all over the place where the blow was given. As this matter is brittle, however, and the same mass will not serve often for the experiment, the best method is to dip iron rods in it while melting, and these will be covered with the matter, and will answer the purpose easily and often. Mem. Acad. Par. 1693.

This is a combination of quick-lime with the acid of sal ammoniac.

PHOSPHORUS, Antimonial, is the name of a substance having the qualities of the phosphorus discovered by Mr. Geofroy, in his experiments on antimony. This gentleman had prepared a soap from pot-ashes, quick-lime, and oil, with which he made several experiments on antimony; among others, he was desirous, by means of this, to reduce some diaphoretic antimony, which he had before made from two parts of the regulus of antimony, and three parts of nitre; but, instead of the reduction which he was labouring after, his operation afforded him a much more singular phenomenon: the result of them being a phosphorus, which he had never thought of; a matter which, after having remained perfectly quiet while close stopt down, took fire as soon as ever it was exposed to the air; and that with a violent detonation, and darting every where a shower of fire.

It is easy to see, that there are in the preparation all the requisites for such an effect; nitre, charcoal furnished by the burnt soap, and sulphur both from the soap and from the regulus of antimony; and to all these a sort of calx, either

PHOSPHORUS.

either from the soap, or from some earthy parts of the antimony. It is easy to conceive, that all these substances, coming into a mixture together, should be ready to catch fire and blaze, upon a proper application; but it is not less difficult to account for the effects being produced merely by the air, after the whole had been for a long time in a state of rest.

The method of preparing this new species of phosphorus is this: Mr. Geoffroy mixed two ounces of his soap with one ounce of this diaphoretic antimony; this mixture, being put by little and little into a red-hot crucible, took fire, and swelled very much; after it had done flaming, the mass subsided, and became a red or fire-coloured substance, of an even surface, but still throwing up a vast quantity of blueish-green luminous vapours; and all this regularly happened on every fresh throwing in of the matter, without the least variety. When the whole quantity was thrown in, and had ceased to give any flame or luminous vapour, it remained in the crucible in the form of an inverted mushroom, being hollow, very porous, and of a black colour. When the crucible was taken out of the fire, the edges of this substance were beaten down into the middle, and the whole covered with an ounce of fresh soap; when this last soap was burnt, and a small blueish flame appeared upon the surface of the mass, the crucible was covered with a lid, and a large quantity of charcoal laid upon it, and the fire blown up very briskly by an hundred blasts of the bellows, or thereabouts; but, notwithstanding the fierceness of the fire, there was no fluid scoria formed, but the whole mass remained spongy and porous; the fire was then suffered to go out, and the crucible placed in the corner of the laboratory at rest for five hours. In the evening, when the crucible was perfectly cold, Mr. Geoffroy went to examine the matter, and a servant went to uncover the mass, by removing its surface with an iron instrument; but the moment the air was admitted, the whole mass took fire, burning with a very considerable noise, and darting its flames every way to a great distance.

Mr. Geoffroy repeated the process several times, and always with the same success, whether he used his own diaphoretic antimony, or that made in the common manner. The great caution to insure the success, seems to be taking care of not carrying the fire too far before the addition of the last quantity of soap. Mem. Acad. Scien. Par. 1736.

PHOSPHORUS of the Bern-stone, is a name given to stone (which, when heated, becomes a sort of phosphorus) from Bern, in Switzerland, the place where it is found.

This substance was sent to the members of the Royal Academy at Paris, by M. Bourguet, and referred by them to the examination of M. du Fay, whose account of it is published in Mem. Acad. Paris, 1724.

The Bern-stone is of a moderate hardness, considerably pellucid, and usually colourless, or whitish, though sometimes with a tinge of green, yellow, or some other colours: it is composed of a number of plates or flakes, laid over one another in the manner of the island crystal; and, therefore, like that body is plainly a spar. It breaks into several faces, and has different angles; but of a somewhat determinate measure, the acute ones being of sixty degrees, and the obtuse ones of one hundred and twenty.

This stone, when heated at one of its angles with the flame of a lamp or candle, splits by means of the flame's insinuating itself into the interstices of the plates that are less firmly united; and these separate, and some fragments usually fly off with considerable violence. One of these pieces, carried into an obscure place, appears surrounded

with a blue flame, which lasts about a minute. And it is to be observed, that these pieces which fly off have all the shape of an irregular pyramid, with an uneven base. If this stone be put into a crucible and surrounded with coals, it becomes a very beautiful phosphorus. The whole bottom of the crucible is seen, even though it be in broad daylight, shining with a bright and beautiful blueish white; and if it be carried into a dark place, the light is seen much more beautifully. If, after it is cold, it be again heated in a crucible, in the same manner, it shews the same bright appearance. After this, if it be tried a third time, it does not shine at all. According to all these phenomena, the effects of fire upon this stone seem to depend on a sulphur contained in it, probably of the same nature with that which enters the composition of the metals. This may, by means of a heat, such as that given by the candle or in the crucible, disengage itself so far from the body of the stone as to take fire; and when it has burnt so long as to consume itself, the luminous property of the stone seems to cease.

The coloured gems are crystals of a peculiar kind, tinged with what has been called the sulphur or phlogiston of metals: this sulphur gives them their colour, and consequently it ought to give them the properties of the Bern-stone, if it were not too fixed to be dissipated in the same easy manner, and to take fire in the dissipation. And it appears, on trial, that the battard emeralds of Auvergne and other places, the matrix of the amethyst, the fragments of some of the accidental jaspers, the hyacinths, and some sort of rubies, are all phosphoruses of the nature of the Bern-stone, but with different degrees of brightness. The mother of the emerald, the yellow jasper, the water sapphire, the malachite, the opal, and the garnet, have none of them any of this property.

Since the same sulphurs, which take fire in the Bern-stone, are what give colour to these other stones, it should seem, that those, which are not of this phosphorus kind, nor give a light after being heated, should not lose their colours in the fire; and this is found to be true in the garnet, which does not lose any part of its colour, nor is it at all luminous; whereas the hyacinth, and some of the jaspers and other stones, which lose a part of their colour, not the whole, in the fire, become also in part luminous, or more so, in degree, according to the quantity of colour which they lose. This, however, is no certain rule, since the mother of the emerald, the topaz, and some other stones, lose all their colour, and yet are not at all luminous. The reason of this seems to be, that the sulphurs are driven out of these stones so slowly, and in such minute quantities, that they are not at any time collected into body enough to be capable of flame. There is nothing to be objected as to the Bern-stone shining; though they are usually white, they may possess no smaller portion of sulphurs than the coloured stones; only in those the sulphurs may be colourless, or white in themselves. It may be possible also, that the sulphurs in a stone of this kind may be dispersed in such small molecules, as not to form a body sufficient to give any colour; but when collected, in order to be driven off in the fire, they may then be sufficient in quantity to give a blue tinge to the flame.

The island crystal, which is also a species of spar, and which greatly resembles this Bern-stone in many particulars, flies to pieces also in the same manner, on being heated; and when carried into the dark, this also gives some sparks of light, but they are few in number, and loosely scattered over the surface: when this stone is burnt a little in the crucible, there is some small appearance of flame, with a
smell

PHOSPHORUS.

smell of sulphur, and the matter in the bottom of the crucible is found shattered to pieces; but all the pieces are regular parallelepipeds, as was the original mass.

It is to be observed, that the Bern-stone, and others of the same kind, which only shine in the dark, and that only for a few minutes, when first taken out of the fire, are, properly speaking, endued with no other luminous quality than that of a burning coal; but their light, having been generally unobserved, and requiring darkness to shew it, has obtained for them the specious title of *phosphori*.

PHOSPHORUS, *Canton's*, is an artificial phosphorus, the method of preparing which was discovered by the late ingenious Mr. Canton, and published in the *Phil. Trans.* for 1768, vol. lviii. p. 337, &c.

This is much superior to any single natural substance, and has the advantage of being very easily and cheaply prepared. The process is as follows: calcine some common oyster-shells, by keeping them in a good coal fire for half an hour; let the purest part of the calc. be pulverized, and sifted; mix with three parts of this powder one part of the flowers of sulphur; let this mixture be rammed into a crucible of about an inch and a half in depth, till it be almost full; and let it be placed in the middle of the fire, where it must be kept red-hot for one hour at least, and then set by to cool: when cold, turn it out of the crucible, and cutting, or breaking it to pieces, scrape off, upon trial, the brightest parts; which, if good phosphorus, will be a white powder, and may be preserved by keeping it in a dry phial with a ground stopple. The quantity of light which a little of this phosphorus gives, when first brought into a dark room, after it has been exposed for a few seconds, on the outside of a window to the common light of the day, is sufficient to discover the time by a watch, if the eyes have been shut, or in the dark, for two or three minutes before. By this phosphorus celestial objects may be very well represented; as Saturn and his ring, the phases of the moon, &c. if the figures of them, made of wood, be wetted with the white of an egg, and then covered with the phosphorus. And these figures appear to be as strongly illuminated in the night, by the flash from a near discharge of an electrified bottle, as by the light of the day. This phosphorus receives no injury from being exposed to the direct rays of the sun, which is the case of some of the more delicate kinds, as Beccarius has remarked, and Lemery supposed with all. However, it cannot be exposed to moisture without losing its property of imbibing and emitting light, and also its whiteness. Mr. Canton found, that it was more affected by mixture with spirit of wine than with ether. It had been long known, that heat promotes the expulsion of the light, which has been formerly imbibed by these phosphori. Mentzel, who wrote soon after the discovery of Baldwin's phosphorus, asserted, that it had the property of becoming luminous by heat only; the same fact was observed by M. du Fay; but the principle on which it depended was discovered by Beccarius, M. Margraaf, and Mr. Canton, independently of one another. Beccarius was first of opinion with Mentzel, that the light was produced by heat; but finding by repeated trials, that, without previous exposing to the light, heat had no effect, he relinquished that opinion. M. Margraaf fell at first into the same mistake with Beccarius; but he afterwards observed, that the phosphorus would not shine by being placed upon a hot furnace, unless it had been exposed to the light two or three days before. Upon the whole, he concludes, that the light is held in this substance by attraction, and afterwards expelled by heat. Mr. Canton also, without any knowledge of the observations of Beccarius

and Margraaf, found by a variety of experiments, that, when his phosphorus had imbibed light, and had emitted all that it could in the common state of the atmosphere, it would emit more upon the application of heat, but that a continuance of the same degree of heat would only make it luminous for a certain time. Whence he infers, that there is a strong attraction between light and the particles of natural bodies: and that the strong vibrations into which heat throws them, compels them, as it were, to quit their hold of each other; and the light, which this phosphorus gives, by being heated to a certain degree, appears to be caused by its throwing off adventitious particles, and not by any of its own; since its light will decrease, and be entirely gone, before the phosphorus be hot enough to shine of itself, or to emit particles of light from its own body. Lemery and Muschenbroeck have observed, that the Bolognian phosphorus imbibes less light when hot than cold; because it appears less bright when carried into a dark room; but this circumstance is accounted for by Mr. Canton, by its parting with its light faster when hot than when cold, and, therefore, parting with more in the time of the conveyance from one place to another: and this, he also says, seems to be the cause why the Bolognian phosphorus never appears so bright after it has been illuminated, and, consequently, in some measure heated, by the direct rays of the sun, as after it has been only exposed in the shaded open air to the common light of the day. However, there is reason to imagine, that the same degree of heat, which disposes the phosphorus to throw off the light after it has been imbibed, must likewise render it indisposed to receive it. For an account of the result of Mr. Canton's experiments on this substance in favour of the materiality of light, see LIGHT.

PHOSPHORUS, *Wilson's*, a substance belonging to the class of solar phosphori, which Mr. B. Wilson discovered, and which is one of the simplest and most powerful of all the phosphori belonging to this class. The method of preparing it is as follows: Select twenty oyster-shells, the thicker the better; then take from a fire that is briskly burning, most of the flaming coals, but not all of them; strew the shells over the surface, and replace the coals that have been taken off. In about an hour's time take out the calcined shells, breaking them as little as possible; and after exposing them for a few minutes to the light, they will be found to have acquired a high degree of phosphorescence, glowing in the dark, in a very beautiful manner, with most of the prismatic colours. If the shells are sufficiently heated in a close crucible, they will exhibit prismatic colours, chiefly blue and green, though not so bright as by the former method. If the calcination is effected in an iron crucible, all those parts of the shells that are in contact with the sides of the crucible will glow with a red light. The contact of inflammable matter, and particularly charcoal, with the shells during calcination, appears very much to contribute to the brilliancy of the phosphorus: hence it is, that if the shells are calcined in a crucible in contact with thin plates of steel, the phosphorus thus produced will be much more bright, and of more various colours, than where plates of iron are employed; and, on the other hand, if flat pieces of charcoal are made use of, the intensity of the colours, especially the blue, green, and red, is far greater than in those produced by steel.

The colour of the light, in most phosphori that have been presented to the light, and that are then carried into the dark, is white or reddish-white; but in Wilson's phosphorus, not only white colours, but all those of the prism make their appearance, sometimes being all united in a single

PHOSPHORUS.

single specimen, at other times each piece exhibiting only one or two colours. In every species of solar phosphorus, the light, after having been extinguished, may be increased for any number of times, without the smallest apparent diminution of brilliancy, by simple exposure for a few seconds to the light. If the phosphorus be moderately heated, when it is presented to the light, its luminousness will be very sensibly augmented. If a common box smoothing-iron, heated as usual, be placed for half a minute on a sheet of dry white paper, and the paper be then exposed to the light, and afterwards examined in a very dark closet, the whole paper will be luminous, and the part on which the iron box had stood will be much more shining than the rest. It is observed that the variation of the temperature produces remarkable effects on phosphori, *after* having been exposed to the light. If a thin glass tube be filled with Canton's or Wilson's phosphorus, and as soon as it is brought into a closet made very dark, be plunged half way into a freezing mixture for a few minutes, it will be found, on again withdrawing the tube, that the cold portion is much less luminous than the other; and if the freezing mixture has been sufficiently powerful, it will be entirely extinguished. The luminous property in this case is suspended, and not exhausted: for as the dark part of the tube begins to acquire the temperature of the surrounding air, its light will revive, and it will remain longer than that of the other part of the tube, in proportion to the time of its being kept in the freezing mixture. From hence it would seem to follow, that at a very low temperature the present class of solar phosphori would cease to exist. As cold retards, heat quickens the emission of light from phosphoric substances. If the tube just mentioned be dipped half way into boiling water, the immersed part will exhibit a great increase of lustre, which in a minute or less time will be succeeded by total darkness; while the unheated part will shine for a much longer time, though with less splendour. If any one of these phosphori, kept in the dark till it is totally extinguished, be placed, without being again exposed to the light, in the warm hand, its luminousness will for a short time be renewed; and if, when the hand fails to produce the effect, it be placed in boiling water, a further emission of light will take place; and, finally, it may be entirely exhausted of its light, by being placed on a metallic plate, heated nearly to redness. Hence it appears, that there are two causes of the extraordinary brightness exhibited by solar phosphorus, when strongly heated immediately on being introduced into the dark room: in the first place, there is a greater quantity of light actually given out; and, secondly, the whole is discharged in perhaps a twentieth of the time in which even a part would be exhausted at the common temperature.

Two theories have been proposed, in order to account for the origin of light in these substances. One theory ascribes it simply to the solar light, which they had previously imbibed; and the other attributes it to the inherent light of the phosphorescent substance itself. The advocates of the first theory allege, that previous exposure to the light is necessary to the phosphorescence of these substances, and that the period of its greatest brilliancy is the moment of its being placed in the dark, where it regularly and rapidly diminishes till it becomes extinct. Beccaria's experiment is also urged in favour of this theory: he found that those phosphori, which in the usual circumstances emit a white light, give out coloured rays in the dark, corresponding to those which they receive from the sun, with the interposition of a plate of coloured glass. The accuracy of this fact has been doubted. Du Fay's experiments, made before those of

Beccaria, tend to a directly opposite result; the light emitted by the phosphorus being of the same tint, whatever was the colour of the glass through which the rays passed to the phosphorus. Others have failed in repeating Beccaria's experiments. Mr. Wilson, in particular, had made many experiments in reference to this point, which, with their results, he has detailed in his *Treatise on Phosphorus*. His facts would lead us to conclude, that the phosphorescent light is not merely that which was previously imbibed from the sun; and yet they do not prove that it is properly inherent in the phosphoric substance itself.

The solar phosphori may be excited not only by the rays of the sun, but by any other light that is sufficiently powerful; and those phosphorescent substances which are most brilliant, in consequence of exposure to the light of day, are most easily excited, as we might naturally expect, by other luminous bodies. However, the rays of the moon, even when concentrated in a lens, appear to be incapable of illuminating even the most sensible kinds of phosphori. The light of a single candle, or the momentary flash from the explosion of a little gunpowder, or from an electrical discharge, are sufficient to render Wilson's phosphorus, when well prepared, very visibly luminous. It is not very certainly known what is the effect of the different gases on the luminous property of these bodies. Aikin's *Dict. of Chem. and Min.*, art. PHOSPHORUS. See LIGHT.

PHOSPHORUS, *Fœcalis*, a very fine kind of phosphorus, exhibiting many wonderful phenomena, and prepared from human dung mixed with alum.

Mr. Homberg, who was the inventor of it, gives the method of preparing it in the following manner: take four ounces of human dung newly made, mix it with the same quantity of roach alum grossly powdered; put the mixture into a small iron ladle, capable of holding about a pint; set it over the fire in a chimney, and it will melt together, and become as fluid as water; let it boil gently over a small fire, continually stirring it with an iron spatula till it is dry; it will then be difficult to stir, but it must be kept stirring about, and all the lumps it runs into must be broken, and what adheres to the sides of the ladle stirred in and blended with the rest; this must be continued till it is perfectly dry, and the ladle must be now and then taken from the fire, and the matter stirred about in it, that it may now grow red-hot. When the whole is thus perfectly dried, it will still be in little lumps, and when cold it must be rubbed to powder in a metal mortar; it must then be put into the ladle, and set over the fire again; it will then become a little moist again, and run into clods and grumes, but it must be again stirred till dry; when cold it is to be powdered again, and a third time put into the ladle; and when perfectly dried this time, it is to be laid by in a paper in a dry place: thus is the first or preparatory operation finished.

Take two or three drams of this powder, put it into a small matras, capable of holding an ounce and a half of water, and which has a neck six or seven inches long; put a paper stopper lightly into the neck of the matras; then take a small crucible of three or four fingers breadth high, put two or three spoonfuls of sand into it, then set the bottom of the matras on the sand, and take care that no part of it touches the sides of the crucible; fill up the rest of the crucible with sand, and let the whole body of the matras be covered with it; then set the crucible in one of the common little earthen furnaces, and make a charcoal fire about it; for the first half hour let the coals only reach up to the middle of the crucible, but afterwards lay them up to the rim in it; continue this fire about half an hour, or till the powder within the matras is red-hot; then pile up more charcoal

PHOSPHORUS.

charcoal above the rim of the crucible, and continue this fire an hour, after which let the whole cool. There will arise a large quantity of fumes during the operation, and they will often throw out the stopper of the matras; but this must be replaced, and the fire a little abated in that case; when these fumes cease, the fire may be raised without hurting the process, when the crucible is so cool that it may be taken out of the furnace without burning the hands. This is to be done, and the matras is to be half raised out of the sand, to make it bear the cold by degrees, and its mouth must then be stopp'd closely with a cork, instead of its paper stopper. If, on shaking the matras about, the matter falls into powder, it is a proof that the operation has been well performed; but if it hang together in form of a cake, it is a sign that the matter was not well roasted in the ladle before the putting it into the matras.

When the operation has been well performed, and the matter is in powder in the matras, pour out a small quantity of it on a piece of paper, and immediately stop the matras again; the powder upon the paper will immediately fume and take fire, burning the paper, and any other combustible matter that is in the way. If there has been too much of the powder poured out of the matras, it must not be returned in again; for though that should be done before it begin to smoke, yet it will certainly set fire to all that is in the matras: from this it may be easily seen also, that the matter cannot be emptied out of the matras into a phial, but must always be in the vessel in which the calcination was made.

If too much alum be used, the powder will not take fire at all: it will be of different colours, according to the vessel the first calcination was made in, and according to the degree of fire that was used; hence it is sometimes black, sometimes brown, sometimes red, green, yellow, or white.

It takes fire equally well in the day-time and in the night, and that without the mixture of any other substance, or without the least rubbing, or any other circumstance beside the mere exposure to the air. In this it differs from all the other known artificial phosphori; for that of urine requires a small degree of heat, in order to its burning; the smaragdine phosphorus requires a considerable degree; the Bononian stone does not shine, except after having been exposed to the day-light; and all the others require violent rubbing, or a smart blow, to produce their light.

If it be desired to keep this powder good for any time, it must be put in a dry place where there is not too much heat; the mouth of the matras must be kept close stopp'd, and its body covered with paper; and the place where it stands must not be in too strong a light; for the open day-light has been often known to weaken its power, and, in fine, wholly to spoil it through the glass. Mem. Acad. Par. 1711. See PYROPHORUS.

PHOSPHORUS, *Fulgurating*. See FULGURATING.

PHOSPHORUS *Metallorum*, a name given by some chemists to a preparation of a certain mineral spar, which is found in the mines of Saxony, and other places, where there is copper. The spar to be used on this occasion is that kind which is tinged green, and from its, in some degree, resembling the colour of the emerald, is called by some *pseudosmaragdus*, and by others *lapis smaragdi mineralis*. This is to be powdered very fine, and this powder is to be laid on a flat plate of copper, iron, or any other metal: this plate is then to be set over some lighted charcoal, and the whole placed in a dark place. The spar will receive its necessary degree of heat for shining long before the metal will, and, consequently, as soon as it begins to shine,

the fire is not to be made any bricker. While the plate of metal is held in this degree of heat, and does not appear at all red, the powder upon it will shine like a lighted coal, and will continue so for some time. If it be removed away, and suffered to cool, it will be fit to repeat the experiment a second time with, but its light will not be so strong as before. Phil. Trans. N. 244. p. 365.

PHOSPHORUS *of Sulphur*, the name given by the French academicians to a new-discovered species of phosphorus, which readily takes fire on being exposed to the open air. See PYROPHORUS.

The invention was M. Le Fevre's, and the process is this: the ingredients are two drams of common sulphur, half an ounce of steel filings, ten grains of colophony, and six drams of common water. These things being all weighed and set apart, powder about half a dram of the sulphur in a small mortar, then add the colophony, and afterwards the remainder of the sulphur. When this is all reduced to a fine powder, put in the filings of steel, and rub the whole together till it is so thoroughly mixed, that the steel does not appear, but the colour of the whole looks every where uniform and regular; then add about twenty drops of the water; and after beating the whole together add as much more, and continue to do so till the mass is of the substance of a paste, but not too moist. Put this paste into a small matras that will contain about three ounces, and pour on it more of the water till it swim above the surface of the paste near a quarter of an inch. The matter of the paste will then break, and appear in form of a granulated powder under the water; put the matras on a sand-furnace, but give it no greater heat than that the hand can bear to lie upon the matras. When it begins to heat, the mixture will ferment and swell, and become black; it is then to be stirred with an iron rod, and a little more water must be added every quarter of an hour, till the whole is used. The matter will then be very black and liquid; and it is to be then taken from the fire, and set by for the whole night. This is the first and most essential part of the operation, and in this great care is to be taken that the fire be not too violent; for if the sulphur be burnt the operation will be spoiled; and the matter would ferment so high as to run over at the mouth of the vessel.

To finish the operation, a little water must be added to the matter, so as to swim over it, and the vessel must be again set in the sand, and a stronger fire given than before; this is known to be strong enough when there is any humid vapour observed to arise out of the mouth of the vessel. This fire is to be continued about two hours, that the greater part of the humidity may be evaporated; which is known by the iron rod finding some resistance when put into the vessel, and the matter it brings up being granulated and solid, or no longer moist, it must then be immediately taken from the fire, and the whole is then finished. It is necessary to be very exact in this last and critical minute; for a very little longer standing on the fire will burn the sulphur, and render all the former care of no effect. The black matter remaining in the matras is to be taken out, and the sides scraped clean with an iron rod; any piece of this that happens to fall upon a paper takes fire in a very little time, and burns away like the other phosphorus. The process is a very nice one, but, by observing all the rules here laid down, several persons have succeeded in making the phosphorus to perfection: the whole intent of the operation seems to be to join together the minute particles of steel and sulphur, which when thus joined cannot fail to be very inflammable, and to take

fire on receiving the smallest humidity from the air to make them ferment.

It cannot but be observed, that this phosphorus is founded on Lemery's experiments of steel and sulphur taking fire together; but this is a much more nice and accurate operation, and a fine improvement on the original plan, which was only by mixing large quantities of steel filings and sulphur together into a paste with water, and burying this in the earth to make it take fire of itself, and thus represent the natural phenomena of volcanos, thunder, lightning, &c. Mem. Acad. Par. 1728.

John Baptist Beccaria has shewn, Phil. Trans. vol. lxi. part i. art. 25. that the phosphorus composed of sulphur and calcareous earth, imbibed the peculiar coloured rays to which it had been exposed. Thus, having exposed different phosphoric pieces to rays of the sun transmitted through green, yellow, and red crystals, he observed, that each of them, when afterwards viewed in the dark, exhibited that colour to which it had been exposed. This observation is decisive in favour of the opinion, that phosphorus of this kind emits the same light that it receives, and no other; and that the light is not produced, but expelled by heat.

This experiment, which has often failed, for want of employing good glasses, or on account of the weakness of the solar rays, has been repeated by professor Allamand of Leyden; who says, that having exposed a prepared (probably by calcining it with some sulphureous substance) piece of the Bononian calcareous phosphorus to the coloured rays of the sun, after their being separated by one of his prisms, and looking to it in the dark, he found the phosphorus gave the colour of the separated rays to which it had been exposed.

PHOSPHORUS, *Aquatic*, a name given by Dr. Leigh, in his History of Lancashire, to a water found near Wigan in that county, which takes fire on holding a lighted candle to it. It is not properly the water, however, that takes fire in this case, but a steam which bursts out of the ground with it. The author also calls it a sulphurated water; but that very improperly, for it contains no sulphur, but only issues out with this bituminous vapour.

PHOSPHORUS, in *Astronomy*, is the morning star, or the planet Venus, when she goes before the sun.

The Latins call it *Lucifer*; the French *etoile de berger*; the Greeks *phosphorus*, from *φως*, light, and *φέρω*, I bear, or bring.

PHOSSA, in *Ornithology*, a name understood by some to express the whole genus of pigeons, but more properly it is the name of one species only, the *palumbus torquatus*, or ring-dove. See COLUMBA *Palumbus*.

PHOTIÆ, in *Ancient Geography*, an episcopal town of Asia, in Phrygia Salutaris.

PHOTINIANS, in *Ecclesiastical History*, a sect of ancient heretics, in the fourth century, who denied the divinity of Jesus Christ.

They took their name from Photinus their chief, who was bishop of Sirmium, and a disciple of Marcellus. This prelate published, in 343, his opinions concerning the Deity, which were equally repugnant to the orthodox and Arian systems. He maintained, that Jesus Christ was born of the Holy Ghost and the Virgin Mary; that a certain divine emanation (which he called the Word) descended upon this extraordinary man; that on account of the union of the divine word with his human nature, Jesus was called the son of God, and even God himself; and that the Holy Ghost was not a distinct person, but a celestial virtue proceeding from the Deity. He was condemned by both parties in the

councils of Antioch and Milan, held in the years 345 and 347, and by the council of Sirmium in 351. He was afterwards degraded from the episcopal dignity, and died in exile, in the year 372 or 375. His opinion was afterwards revived by Socinus.

PHOTINUS, in *Biography*. See the preceding article.

PHOTINX, or crooked flute: an Egyptian instrument. Its shape was that of a bull's horn, as may be seen in many gems, medals, and remains of ancient sculpture. Not only the form of this instrument, but the manner of holding it, is described by Apuleius, in speaking of the mysteries of Isis: "Afterwards," says this author, "came the flute players, consecrated to the great Serapis, often repeating upon the crooked flute turned towards the right ear, the airs commonly used in the temple." All the representations in sculpture which we have seen of this instrument, have so much the appearance of real horns, that they encourage a belief of its great antiquity; and that the first instruments in use of this kind, were not only suggested by the horns of dead animals, but that the horns themselves were long used as musical instruments, at least those founded by the Hebrew priests at the siege of Jericho, we are repeatedly told, were trumpets made of ram's horns.

PHOTIUS, in *Biography*, a patriarch of Constantinople in the ninth century, was of a noble Constantinopolitan family. His wealth and interest raised him to the highest offices of the state, while he enjoyed the reputation of being the most learned and accomplished man of his age. When he was a captain of the guards he was sent on an embassy to the caliph of Bagdad, and he employed his leisure in reading and literary composition. He afterwards became secretary of state under the emperor Michael III. In this situation he contracted an intimacy with the emperor's uncle, who, after he had procured the exile of the patriarch Ignatius, persuaded the emperor to raise Photius to that dignity. At this time he was a layman, but in the space of six days he went through the gradations requisite for priest's orders, and on Christmas day, 858, he was consecrated patriarch of Syracuse. Photius was recognized by the metropolitans of his patriarchate, and proceeded to the solemn deposition of Ignatius. The elevation of Photius caused a great schism, and he exercised severities on those who adhered to his rival. The emperor Basil expelled him in 869, an act that was confirmed by a council summoned for the purpose, who pronounced an anathema, as well as deposition, against the fallen patriarch. Afterwards he obtained the emperor's favour, and on the death of Ignatius he resumed his dignity with a strong hand. Basil obtained from pope John VIII. his consent to the measure, which was ratified at a council holden in presence of the pope's legates in 879. In 886 Leo caused him again to be deprived, and confined in a monastery, where he died in 891. His principal works are; 1. "Myriobiblon or Bibliotheca," composed on his embassy to Bagdad, consisting of an abstract and critical judgment of 280 different writers in the departments of history, oratory, grammar, philosophy, theology, &c. of many of whom no other relic remains: this was printed by Heshelius in 1601, but the best edition is that of Rouen, Gr. and Lat. 1653. The book which at present bears that name, is not the real production of Photius; and it has been supposed that not more than half of it can be safely attributed to this learned and turbulent bishop. 2. "Nomocanon," or a collection of the canons of the church, printed with the commentaries of Balsamon at Paris in 1615. 3. "Epistolæ," or a collection of Letters, printed by R. Mountagu in 1651. 4. His celebrated

celebrated Lexicon, which, imperfect and mutilated as it is, is more valuable to the critical scholar than ten myriobibla. The various MSS. of this Lexicon, in different libraries on the continent, are mere transcripts from each other, and originally from one, venerable for its antiquity, which was formerly in the possession of the celebrated Thomas Gale, and which is now deposited in the library of Trinity college, Cambridge. This MS., which is on parchment, bears such evident marks of antiquity, that it may not unreasonably be supposed to have been a transcript from the author's copy. It is written in various hands. The compendia, which are used in some parts of it, are extremely difficult to decipher, though, on the whole, they are less so than the contractions which occur in many MSS., and particularly those in the library of St. Germain. A copy of this Lexicon, at Florence, was transcribed about the end of the 16th century, by Richard Thomson, of Oxford, who probably intended to publish it. (See Scaliger Epist. p. 503. printed 1715.) Professor Porson had transcribed and corrected this valuable Lexicon for the press, and after it had been consumed by fire, he began the task afresh, and such were his incredible industry and patience, that he completed another transcript in his own exquisite hand-writing. Mr. Porson's copy of the Codex Galeanus is said to be among the papers of that incomparable scholar, which are preserved by the learned society of which he was long a distinguished ornament. But whilst the publication of it was anxiously expected and delayed, an edition appeared at Leipzig in 1808, by Godfrey Hermann, from two MSS., both of them extremely inaccurate.

PHOTOMETER, or *Measurer of Light*, as the name, derived from $\varphi\omega\varsigma$, *light*, and $\mu\acute{\epsilon}\tau\rho\omega$, *I measure*, imports, in *Optics*, an instrument contrived for measuring the different intensities of light. That some luminous bodies give a stronger and others a weaker light, and that some reflect more light than others, are facts that have been always known, and that are sufficiently obvious. But it is not easy to estimate with accuracy the comparative intensity of light afforded by any two, or more, luminous objects. For this purpose, it is necessary to assume as a principle, that the same quantity of light, diverging in all directions from a luminous body, remains undiminished at all distances from the centre of divergence. Thus, we must suppose, that the quantity of light falling on every body is the same as would have fallen on the place occupied by its shadow; and if there were any doubt of the truth of the supposition, it might be confirmed by some simple experiment. It follows that, since the shadow of a square inch of any surface occupies, at twice the distance of the surface from the luminous point, the space of four square inches, the intensity of the light diminishes as the square of the distance increases. We can judge with tolerable accuracy of the equality of two lights by the estimation of the eye; but we cannot form any idea of the proportions of light of different intensities. If, however, we remove two sources of light to such distances from an object, that they may illuminate it in equal degrees, we may conclude that their original intensities are inversely as the squares of their distances. To this subject Mr. Bouguer seems to have first directed his attention. The methods which he used for measuring the proportion of different lights, are described by Dr. Priestley in his "History of Light, &c." as follow. He took two pieces of wood or pasteboard, in which he made two equal holes, over which he drew pieces of oiled or white paper. Upon these holes he contrived that the light of the different bodies he was comparing should fall, while he placed a third piece of pasteboard, to prevent the two lights from mixing with one

another. Then placing himself sometimes on one side and sometimes on the other, but generally on the opposite side of this instrument, with respect to the light, he altered their position, till the papers in the two holes appeared to be equally enlightened. This being done, he computed the proportion of their light by the squares of the distances at which the luminous bodies were placed from the objects. If, for instance, the distances were as 3 and 9, he concluded the light they gave were as 9 and 81.

When any light was very faint, he sometimes made use of lenses, in order to condense it, and he enclosed them in tubes or not, as his particular application of them required. To measure the intensity of light proceeding from the heavenly bodies, or reflected from any part of the sky, he contrived an instrument resembling a kind of portable camera obscura. He had two tubes, of which the inner was black, fastened at their lower extremities by a hinge. At the bottom of these tubes were two holes, three or four lines in diameter, covered with two pieces of fine white paper. The two other extremities had each of them a circular aperture, an inch in diameter; and one of the tubes consisted of two, one of them sliding into the other, which produced the same effect as varying the aperture at the end. When this instrument is used, the observer has his head, and one end of the instrument so covered, that no light can fall upon his eye, besides that which comes through the two holes above mentioned, while an assistant manages the instrument, and draws out or straightens one tube, as the observer directs. When the two holes appear equally illuminated, the intensity of the lights is judged to be inversely as the squares of the lengths of the tubes. In using this instrument, it is necessary that the object should subtend an angle larger than the aperture of the tube from its other end; for, otherwise, the lengthening of the tube has no effect. To avoid, in this case, making the instrument of an inconvenient length, or making the aperture too narrow, he has recourse to another expedient. He constructs an instrument, consisting of two object-glasses, fixed in the ends of two tubes, six or seven feet, or, in some cases, ten or twelve feet long, and having their foci at the other ends. At the bottom of these tubes are two holes, three or four lines in diameter, covered with a piece of white paper; and this instrument is used exactly like the former. If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object-glasses; and then the remaining surface of the two glasses will give the proportion of their lights. But, for this purpose, the central parts of the glass must be covered, in the same proportion with the parts near the circumference; because the middle part of the glass is thicker, and less transparent than the rest. If all the objects to be observed lie nearly in the same direction, our author observes, that the two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficing for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a heliometer, or astrometer. (See HELIOMETER.) For some results of the application of these methods for determining the comparative intensities of the light proceeding from different luminous bodies in different circumstances, see LIGHT. Count Rumford has used the first of Bouguer's methods, and contrived an instrument for this purpose, called the "Photometer," of which he has given a description and drawing in the Philosophical Transactions for 1794, vol. lxxxiv. art. 9. The principle upon which it is grounded is, that if two lights shine upon the same surface, at equal obliquities, and an

PHOTOMETER.

opaque body be interposed, the two shadows it will produce must differ in blackness or intensity in the same degree. For the shadow formed by intercepting the greater light will be illuminated by the smaller light only, and reversely, the other shadow will be illuminated by the greater light: that is, the stronger light will be attended with the deeper shadow. But it is easy, by removing the greater light to a greater distance, to render the illumination it produces at the common surface equal to that afforded by the less. Experiments of this kind may be conveniently made by fastening a sheet of white paper against the wall of a room; and placing the two candles or lights intended to be compared, so that the ray of light from each shall fall with nearly the same angle of incidence upon the middle of the paper. In this situation, if a book or other object be held to intercept part of the light which would have fallen on the paper, the two shadows may be made to appear, on separate surfaces, and also a third or perfect shadow, from which both lights are excluded, may be exhibited. If one or both of the lights be removed directly towards or from the paper, as the appearances may require, until the two shadows near the upper angular point of the perfect shadow have the same intensity, the quantities of light emitted by each will be as the squares of the distances from the paper. By some experiments made in this way, in the year 1785, Mr. Nicholson (see his Journal, vol. i.) was satisfied that the degree of illumination could be thus ascertained, to an 80th or 90th part of the whole.

Count Rumford, in his "Account of a Method of measuring the comparative Intensities of Light," directs two burning candles, lamps, or other lights that are to be compared, to be placed at equal heights upon two light tables, or moveable stands in a darkened room; let a sheet of clean white paper be equally spread out, and fastened upon the wainscot or side of the room, at the same height from the floor with the lights, and let the lights be placed over-against this sheet of paper, at the distance of six or eight feet from it, and six or eight feet from each other, in such a manner, that a line drawn from the centre of the paper, perpendicular to its surface, shall bisect the angle formed by lines drawn from the lights to that centre; in which case, considering the sheet of paper as a plane speculum, the one light will be precisely in the line of reflection of the other.

This may be easily performed, by actually placing a piece of a looking-glass, six or eight inches square, flat upon the paper, in the middle of it, and observing by means of it the real lines of reflection of the lights from that plane, removing it afterwards as soon as the lights are properly arranged.

When this is done, a small cylinder of wood, about a quarter of an inch in diameter, and six inches long, must be held in a vertical position, about two or three inches before the centre of the sheet of paper, and in such a manner, that the two shadows of the cylinder corresponding to the two lights may be distinctly seen upon the paper.

If these shadows should be found to be of unequal densities, which will almost always be the case, then that light whose corresponding shadow is the densest, must be removed farther off, or the other must be brought nearer to the paper, till the densities of the shadows appear to be exactly equal; or in other words, till the densities of the rays from the two lights are equal *at the surface of the paper*; when, the distances of the lights from the centre of the paper being measured, the squares of those distances will be to each other as the real intensities of the lights in question at their sources.

If, for example, the weaker light being placed at the distance of four feet from the centre of the paper, it should

be found necessary, in order that the shadows may be of the same density, to remove the stronger light to the distance of eight feet from that centre, in that case, the real intensity of the stronger light will be to that of the weaker as 8 to 4; or as 64 to 16; or 4 to 1; and so for any other distances.

It is well known, that the intensity of any quality proceeding from a centre in straight lines in all directions, like the light emitted by a luminous body, at any given distance from that centre will be as the square of that distance inversely; and hence it is clear, that the intensities of the lights in question at their sources, must be to each other as the squares of their distances from that given point *where their rays uniting, are found to be of equal density*. For putting x = the intensity of B; if P represents the point where the rays from A and from B meeting, are found to be of equal density or strength, and if the distance of A from P be = m , and the distance of B from the same point P = n ; then, as the intensity of the light of A at P is = $\frac{x}{m^2}$, and the intensity of the light of B at the same place = $\frac{y}{n^2}$, and as it

is $\frac{x}{m^2} = \frac{y}{n^2}$ by the supposition, it will be $x : y :: m^2 : n^2$.

That the shadows being of equal density at any given point, the intensities of the illuminating rays must of necessity be equal at that point also, is evident from hence, that the total absence of light being perfect blackness, and the shadow corresponding to one of the lights in question being deeper or fainter, according as it is more or less enlightened by the other, when the shadows are equal, the intensities of the illuminating rays must be equal likewise.

In removing the lights, in order to bring the shadows to be of the same density, care must be taken to recede from, or advance towards the centre of the paper in a straight line, so that the one light may always be found exactly in the line of reflection of the other; otherwise the rays from the different lights falling upon the paper, and consequently upon the shadows, at different angles, will render the experiment fallacious.

When the intensity of one strong light is compared with the intensities of several smaller lights taken together, the smaller lights should be placed in a line perpendicular to a line drawn to the centre of the paper, and as near to each other as possible; and it is likewise necessary to place them at a greater distance from the paper than when only single lights are compared.

In all cases, it is absolutely necessary to take the greatest care that the lights compared be properly trimmed, and that they burn clear and equally, otherwise the results of the experiments will be extremely irregular and inconclusive.

To ascertain by this method the comparative densities, or intensities of the light of the moon, and of that of a candle, the moon's direct rays must be received upon a plane white surface, at an angle of incidence of about 60°, and the candle placed in the line of the reflection of the moon's rays from this surface; when the shadows of the cylinder corresponding to the moon's light, and to that of the candle, being brought to be of equal density, by removing the candle farther off, or bringing it nearer to the centre of the white plane, as the occasion may require, the intensity of the moon's light will be equal to that of the candle *at the given distance of the candle from the plane*.

To ascertain the intensity of the light of the heavens by day or by night, this light must be let into a darkened room through a long tube, blackened on the inside, when its intensity

tensity may be compared with that of a candle or lamp, by the method above described.

To determine the intensity of the direct rays of the sun, compared to the light emitted by any of our artificial illuminators, it may perhaps be necessary, considering the almost inconceivable intensity of the sun's light, to make use of some further contrivances and precautions, but I am convinced, however, (says the author,) that it may be done, and that even with a very considerable degree of precision. And when the relative intensity of the sun's light at the surface of the earth, compared with the intensity of the light of a given lamp, placed at a given distance, and burning with a flame of given dimensions, shall be known; it will then be easy, from the known size and distance of the sun, to compute the relative density of his light at his surface, compared to the density of the light of the flame of the lamp at the surface of that flame.

The intensity of the light emitted in the combustion of iron or of phosphorus in dephlogisticated air, as also that of all other burning, or red-hot bodies, may be compared and determined by this method with the greatest facility and exactness.

Count Rumford afterwards found it expedient to make some alterations in the instruments with which he conducted his experiments; and he thus describes them in their finished state, when he denominated the whole apparatus combined a "photometer." For an account of the construction of this instrument, of the purposes to which it is capable of being applied, and of the author's experiments with it, we refer to the *Phil. Trans. ubi supra*.

Professor Lesley has invented an instrument for the same purpose, and under the same name, which he describes as being constructed in the same manner with his *hygrometer*, only that the upper ball is blown of black glass, or is blackened, and the lower one is quite diaphanous, and free of specks. The former detains the incident light, while the latter transmits it freely. But light, in proportion to its absorption, causes heat, whether uniting with bodies it really constitutes the matter of heat, or only excites heat in the act of combination. But though the black ball acquires constant additions of heat, its temperature will not uniformly and perpetually increase; for the accumulated heat will at last be conducted off by the surrounding air exactly as it is received. The depression of the liquor, therefore, will measure the momentary afflux of light. To prevent the irregular effects of winds, which might accelerate that dispersion, the instrument is inclosed within a glass case. But this case serves also an important purpose, for, by confining the circulation of the ambient air, which alone transfers the continual augmentation of heat, it doubles the performance of the instrument. The cylindrical case should be made of clear glass neatly rounded over, and hermetically sealed at the end. Its width is not of much importance, only it should leave a free space not less than $\frac{1}{10}$ th of an inch round the balls, and at least half an inch at the top. Indeed both the size and form may be regulated by convenience, for I found (says the professor) a receiver of 2200 inches to afford quantities scarcely one-tenth less than those given by a case of the ordinary dimensions.

Since this instrument was first constructed, in the autumn of 1797, Mr. Lesley has been delighted with the nicety of its performance. It not only measures the direct rays of the sun, but the reflected light of the sky, for which it is principally designed. It is sensible to every fluctuation of the atmosphere, marks the progress and decline of the light of day, and the periodic increase and diminution of the brightness of the year. It enables us likewise to estimate other lights, such as the flame of a candle. By comparing two photometers,

it is easy to determine the relative properties of different coloured substances, in reflecting, absorbing, and transmitting light. In the same manner, they will determine the question, whether the particles of light are spread over the prismatic spectrum with equal intensity. By help of this instrument, too, we can measure the quantity of light transmitted through various diaphanous bodies, and that reflected or absorbed at different angles of incidence from polished or rough surfaces; in short, perform with the utmost facility all those ingenious experiments which have exercised the sagacity of Bouguer and Lambert. Another set of inquiries, for which the photometer is nicely calculated, is to discover the conducting powers of different fluids for heat. If the glass case, for instance, be filled with a gas of higher conducting power than common air, the instrument will be proportionally less affected by the same afflux of light, since those are the two balancing conditions. With air, too, of different densities, the effects are materially different. In that way the author has examined various liquids and gases, nay jellies and ice. His experiments on these and other points are completed, and afford results which are satisfactory and important. For a farther account of this instrument, and of a curious and valuable collection of facts established by means of it, we refer to Lesley's "Short Account of Experiments and Instruments on the Relation of Heat to Air and Moisture," 8vo. See *Differential THERMOMETER*.

PHOTOSCIATERICA, a term which some authors use for the art of dialling.

The name is derived hence, that the art not only shews the hours by the shadow of a gnomon, whence it is called *sciaterica*, from *σκια*, shadow; but sometimes also by means of the sun's light, as in spot dials, reflecting dials, &c. from *φως*; lux, light.

PHOVIBAGINA, in *Ancient Geography*, a town of Asia, in Galatia, belonging to the Trocmi. It is called by Ptolemy Carissa and Dudusa.

PHOXINUS, in *Ichthyology*, a species of *Cyprinus*; which see.

PHOXOS, *Φοξος*, one with an acuminated or fastigiated head, that is, sharpened toward the top; the eminences of the forehead or occiput, or both, being depressed, or one or both of those parts beyond measure prominent. But phoxoi are properly those who have the top of their head very much fastigiated and turbinated, and consequently deformed. Therites is described in Homer with such a head.

PHRAATA, in *Ancient Geography*, a town of Asia, which belonged to the Medes, according to Appian.

PHRAATIS GAZA, an island of Asia, in the course of the Euphrates, which was of great extent, and fortified by a wall; situated W.N.W. of Anatho.

PHRADRA, a town of Drangiana, called also Prophthasia. Steph. Byz.

PHRÆNIAN, in the *Botanical Writings of the Ancients*, a name given to a kind of anemone, used in making garlands and other ornaments.

PHRAGANDÆ, in *Ancient Geography*, a people of Thrace, on the confines of Macedonia.

PHRAGONIS, an episcopal town of Egypt, according to the acts of the council held at Alexandria in the year 562.

PHRANGI, a people of Italy, in the vicinity of the Alps. Steph. Byz.

PHRANZA, PHRANZES, GEORGE, in *Biography*, a modern Greek historian, was from his youth employed in the service of the Byzantine court, and was the favourite chamberlain of the emperor Manuel Palæologus, who died A.D. 1427, when Phranza was 24 years of age. He was
master

master of the wardrobe to his successor John, and also to Constantine, the last emperor of the East, by whom he was sent ambassador to the courts of Georgia and Trebifond, for the purpose of negotiating a marriage for the young sovereign. When the Turks took Constantinople, Phranza with his family were made slaves. In a few months, he and his wife were ransomed; but his two children, a son and a daughter, were seized for the seraglio, and lost to their unhappy parents. After this, Phranza became domestic to prince Thomas, brother of the deceased Constantine, who employed him in various embassies. He assumed the monastic habit before his death, which took place at an advanced age. At the request of some noble Corcyreans, he drew up a chronicle of the affairs relating to Constantinople and the Morea, to most of which he had been an eye-witness. This work is brought down to 1461; but though there are many MSS. of the Greek original extant in libraries, it has been published only in the Latin version, or abstract of Pontanus, which, according to Gibbon, is very deficient in accuracy and elegance.

PHRASE, PHRASIS, Φραση, of Φραζω, *I speak*, in *Grammar*, an elegant turn or manner of speech, peculiarly belonging to this or that occasion, this or that art, or this or that language.

Thus we say, an Italian phrase, an eastern phrase, a poetical phrase, or a rhetorical phrase.

A few elegant phrases, pertinently applied, are an ornament of discourse; but, if they come too thick, they have an ill effect, and make the style favour of affectation.

PHRASE is sometimes also used for a short sentence, or small set or circuit of words, constructed together.

In this sense, father Buffier divides phrases into *complete* and *incomplete*.

Phrases are *complete*, where there are a noun and verb, each in its proper function; *i. e.* where the noun expresses a subject, and the verb the thing affirmed of it. They are *incomplete*, where the noun and the verb, together, only do the office of a noun, as consisting of several words, without assuming any thing, and which might be expressed in a single word.

Thus, *that which is true* is an incomplete phrase, which might be expressed in one word, *truth*: as, that which is true satisfies the mind, *i. e.* truth satisfies the mind.

PHRASE, Phrase, Fr., in *Music*, denotes the continuance of an air or harmony, which forms, without interruption, a sense more or less complete, and which is terminated by a cadence more or less perfect. In melody the phrase is constituted by the air; but in harmony, it is a regular series of concords, united together by dissonances expressed or understood.

Phrase is frequently used as synonymous with *passage*, in music. It is in the invention of musical phrases, in their proportion and texture, that the true beauties of music consist. A composer who accents and phrases his passages well, is, according to Rousseau, a man of wit. Upon this principle, Haydn's music is full of *bons mots*. A singer who feels, who marks and accents his phrases well, is a man of taste; but he who only sees crotchets and quavers, keys, measure, and intervals in music,—in short, who only sings in time and tune, however ready and certain he may be, if he feels not the accents and phraseology of what he executes, is nothing more than a vulgar ballad-singer.

PHRASEOLOGY, PHRASEOLOGIA, Φρασιολογια, a collection of the phrases, or elegant expressions, in any language.

PHRAT, the name anciently given to the river *Euphrates*; which see. Phrat is mentioned in scripture, and is

said to have two derivations from the Hebrew, *phar* or *pharatz*, to spread, and *pharah*, to produce fruit or flowers. Vincent.

PHRATRIARCHUS, Φρατριάρχος, among the Athenians, a magistrate that presided over the *phratrria*, or third part of a tribe. He had the same power over the *phratrria*, that the phylarchus had over the tribe.

PHREATA, in *Ancient Geography*, a town of Cappadocia, in Galatia. Ptolemy.

PHREATIS, or PHREATTIUM, in *Greek Antiquity*, a court pertaining to the civil government of Athens, which was situated upon the sea-shore in the Piræus, and derived its name *απο το Φρεατος*, because it stood in a *pit*, or, as others suppose, from the hero Phreatus. The causes heard in this court were such as concerned persons that had fled out of their own country for murder, or those that fled for involuntary murder, and had afterwards committed a deliberate and wilful murder. The first person that was tried in this place was Teucer, upon a groundless suspicion, that he had been accessory to the death of Ajax. The criminal was not permitted to come to land, or so much as to cast anchor, but pleaded his cause in his bark; and, if found guilty, was committed to the mercy of the winds and waves, or, as some say, suffered there condign punishment; if innocent, he was only cleared of the second fact, and, according to custom, underwent a twelvemonth's banishment for the former. Potter's *Gr. Antiq.* vol. i. p. 111.

PHRENES, Φρενη, in *Anatomy*, the diaphragm.

It was thus called by the ancients, from *Φρηνη*, *mind*; because they imagined this to be the seat of the rational soul. Hence,

PHRENESIS, PHRENSY, or Distraction. See **PHRENITIS** and **PARAPHRENITIS**.

PHRENETIC NERVES, called also *diaphragmatic* and *stomachic nerves*, in *Anatomy*, are nervous branches derived from the cervical nerves, which, joining in a trunk, run through the mediastinum undivided, till, arriving near the diaphragm, they again divide, and send off divers branches, some into the muscular, others into the tendinous part thereof.

PHRENIC, an epithet applied to parts belonging to the diaphragm, as the nerve, artery, &c. See **NERVE** and **ARTERY**.

PHRENITIS, in *Medicine*, from *Φρηνη*, *the mind*, sometimes written *phrenesis*, *a phrensy*, or a disorder of the understanding, (*sapientie agritudo*, as Pliny denominates it, *Hist. Nat. lib. vii. cap. 51.*) has been understood, however, in a limited sense from the time of Hippocrates; namely, as a continued ferocious delirium, accompanied by an acute fever, and arising from inflammation of the brain, or its membranes. In the language of modern nosologists, *phrenitis* signifies literally *inflammation of the brain*; the termination *itis* implying inflammation of the organ alluded to, as in *hepatitis*, *enteritis*, &c.

Some writers derive the word from *Φρηνη*, *the diaphragm*, in which organ the mind was anciently supposed to be seated. See **PARAPHRENITIS**.

The symptoms which characterize acute inflammation of the brain are a vehement fever, a violent deep-seated pain in the head, a redness and turgescence of the face and eyes, intolerance of light and noise, continued watchfulness, and an impetuous and fierce delirium. (Cullen, *First Lines*, § 293.) Some writers, indeed, have attempted to establish a distinction, as in the inflammations of other viscera, between the affections of the investing membranes, and of the substance of the brain; and have maintained that the symptoms just enumerated were peculiar to inflammation of the membranes, whilst some degree of coma, instead of wakefulness,

PHRENITIS.

fulness, characterised the inflammation of the cerebrum itself. The fact is, in this, as in other visceral inflammations, that both parts of the organ are commonly involved in the disease; but it is probable that the symptoms are more violent, in proportion to the predominant affection of the membranes; and more obtuse and chronic, as the malady prevails more extensively in the parenchyma or substance.

But, in truth, the symptoms of inflammation of the common sensorium, the centre of sensation and voluntary motion, are not always so simple and uniform as the signs of a similar affection of other organs. The other parts of the body, which are so intimately connected with the source of the nervous power, and some of which are linked to it by direct and particular sympathies, are necessarily more or less involved in the derangements of the brain. Instead of a mere local disease, therefore, this inflammation becomes more peculiarly a general affection of the system. Hence it is justly remarked by most writers on the subject, that pure idiopathic phrenitis is a very rare disease, at least in this climate; in other words, that the congeries of symptoms, constituting the nosological character of the local inflammation above laid down, very seldom occur without great modifications. It sometimes puts on merely the ordinary character of common continued fever, when dissection has demonstrated not only the existence of inflammation, but of suppuration in the brain. Indeed so common is its occurrence in this form, though to a less degree than is followed by the suppurative process, that an ingenious writer has attempted to prove, that all idiopathic fevers are, in fact, cases of inflammation of the brain (see Clutterbuck on Fever); an opinion which we have discussed at length under its proper head. (See FEVER.) It is universally admitted, however, that, except where external mechanical violence has been suffered, a pure idiopathic phrenitis is rarely observed; but that a secondary or symptomatic inflammation of the brain, of a less determined character, is frequently the result of other diseases, and then partakes more of an atonic or passive form; arising, for instance, during the progress of general fever from any cause, or from metastasis in gout, rheumatism, erysipelas, and other acute disorders. It is justly remarked, indeed, by an intelligent writer, that whenever the velocity of the circulation is much increased, there must always be, from the nature of the circulation in the head, a tendency to this complaint, or to congestion in the larger vessels: hence headache, flushing of face, inflammation of the eyes, bleeding from the nose, and other symptoms denoting preternatural distension of the vessels of the head, are among the most frequent symptoms of continued fever of the more acute kind. Wilson on Febrile Diseases, vol. iii. chap. 6.

History of the Symptoms.—Phrenitis often makes its attack with a sense of fullness in the head, flushing of the countenance, and redness of the eyes, the pulse being full, but in other respects natural. As these symptoms increase, the patient becomes restless, his sleep is disturbed, or wholly forsakes him. Sometimes it comes on with tremors of the limbs, and intolerable pains of the hands, feet, and legs; sometimes with stupor and rigidity of the whole body; and sometimes with anxiety, and a sense of tension in the breast, which is often accompanied with palpitation of the heart. Sometimes, again, the stomach is early affected, (by its close sympathy with the brain,) and nausea, and a painful sense of weight in that viscus, sometimes heart-burn and vomiting, are among the earliest symptoms.

The pain in the head soon becomes considerable, and sometimes very acute. The seat of it is various: sometimes it seems to occupy the whole head; sometimes, although

more circumscribed, it is deep-seated and ill defined; and, in other cases, it is felt principally in the forehead or occiput. The redness of the face and eyes generally increases with the pain, and there is often a sense of heat and throbbing in the head, the countenance acquiring a peculiar fierceness.

These symptoms, for the most part, do not last long, before the patient begins to talk incoherently, and to shew other marks of delirium: sometimes, however, delirium does not come on till the fifth, sixth, or seventh day. It gradually increases till it often arrives at a state of phrensy. The face becomes turgid, the eyes stare, and seem as if starting from their sockets, tears, and sometimes even blood, flowing from them; and the patient sometimes resembles a furious maniac, from whom he is principally to be distinguished by the shorter duration of his complaint.

We should, *a priori*, expect in phrenitis considerable derangement in the different organs of sense, which so immediately depend upon the state of the brain; and such is the fact. The eyes are incapable of bearing the light, and false vision, particularly that termed *muscæ volitantes*, or floating motes and flashes of light seeming to dart before the eyes, are frequent symptoms. The hearing is often so acute, that the least noise is intolerable: sometimes, on the other hand, the patient becomes deaf; and it has been even observed, that the deafness and morbid acuteness of hearing sometimes alternate. Affections of the smell, taste, and touch, are less observable.

The pulse is not always so much disturbed at an early period, as might be expected from the violence of the other symptoms, compared with what is observed in idiopathic fevers. In many cases, however, the fever runs as high as the delirium, and the pulse is harder than in common fever; indeed the hard and small pulse is often one of the best diagnostics of the complaint: it is sometimes, though rarely, intermitting. The respiration is generally deep and slow, sometimes difficult, now and then interrupted with hiccup, seldom humid and frequent, which last is a very unfavourable symptom. The deglutition is often difficult, sometimes convulsive. The stomach is frequently oppressed with bile, which is an unfavourable symptom; and complete jaundice, the urine and skin being tinged yellow, sometimes supervenes. Instead of a superabundance of bile, however, there is sometimes a deficiency of it, which seems to afford even a worse prognosis. The fæces being of a white colour, and a black cloud in the urine, have been regarded as fatal symptoms. The black cloud in the urine is owing to an admixture of blood; when unmixed with blood, the urine is generally pale.

Among the most unfavourable symptoms of phrenitis the following may be enumerated; namely, tremors of the joints, convulsions of the muscles of the face, grinding of the teeth, sudden changes of the colour of the face from florid to pale, involuntary tears, a mucous discharge from the nose, the urine being of a dark red colour, or yellow, or black, or covered with a pellicle, the fæces being either bilious or white and very fetid, profuse sweat of the head, neck, and shoulders, paralysis of the tongue, general convulsions, much derangement of the internal functions, and the supervention of the symptoms of other visceral inflammations, particularly of peripneumony. If the delirium changes to coma, and the pulse at the same time becomes weak and the deglutition difficult, the approach of death may be generally expected.

With respect to the *causes of phrenitis*, we have already observed that it is a rare disease in our temperate climate, but is more frequently observed in warm latitudes. The predif-

predisposition seems to consist in the irritability of youth, and of the sanguine temperament, as well as in a passionate temper of mind. The exciting causes are such circumstances, internal and external, as tend to produce an accumulation of blood in the head; among which are the direct influence of a vertical sun in tropical climates, or long exposure to it in hot weather in more moderate heats, especially under great bodily exertions; violent fits of anger; intoxication; concussion, fracture of the skull, or other mechanical violence; long and intense exertion of the mind; certain narcotic poisons, miasmata, and perhaps contagion.

The appearances which are observed on dissection after death vary considerably in different instances, according to the actual seat of the inflammation, and to the duration and violence of the disease. Sometimes the *dura mater* is found reddened by a number of extremely fine vessels, filled with florid blood, which pass between it and the cranium; but this membrane, when inflamed, exhibits less of this crowded state of vessels than many other membranous parts, which are naturally more vascular. Sometimes a layer of coagulable lymph is found adhering upon its under surface, like an adventitious membrane; and sometimes adhesions are formed to a considerable extent between it and the other membranes of the brain. It is not unusual, when the *dura mater* has been inflamed, especially in consequence of some external violence, for suppuration to take place, and pus to be found covering a portion of the membrane. Inflammation of the *pia mater* is more difficult to distinguish for a contrary reason; namely, that in its natural state it is crowded with a great number of minute vessels: when inflamed, however, these small vessels are much more numerous, are filled with a florid blood, and form by their anastomosis a beautiful network: at the same time, there is a stronger adhesion between the under surface of the membrane and the brain than usual. It very rarely happens, that any layer of coagulable lymph is formed in the inflammation of the *pia mater*, which is so very common in that of the *pleura* and the *peritoneum*. When the *pia mater* is inflamed to a high degree, pus is formed, and is sometimes found diffused over the whole surface of the brain. When inflammation has existed in the substance of the brain, it is rarely found extended over any large portion of it, but is rather confined to one or more distinct spots. In this state of disease the inflamed portion becomes of a red colour, although this is seldom very intense. When cut into, the colour is found to arise from a great many small vessels, which are filled with blood; and the part inflamed has no peculiar hardness, but yields nearly the same sensation to the touch, as it would do in a healthy state. If the inflamed portion be upon the surface of the brain, the membranes in the neighbourhood are also commonly inflamed. Inflammation of the brain frequently advances to suppuration, and abscesses are formed in it. When these are of a large size, the weight of the pus breaks down the structure of the neighbouring parts, and they look simply as if they had been destroyed, or very much injured by the pressure. When the abscesses are small, there is an ulcerated appearance of the cavities in which the pus is contained. Portions of the brain become gangrenous occasionally, especially after violent injuries of the head; but this appearance is extremely rare, where inflammation of the brain has originated from any other cause. See Baillie's *Morbid Anatomy*, chap. xxiv.

The cure of *phrenitis* must be conducted upon the same general principles as that of other acute visceral inflammations; and from the particular importance of the organ in-

flamed, the antiphlogistic and evacuant plan must be pursued with the utmost vigour and expedition.

Blood-letting is to be considered as the principal dependence of the practitioner, and the more early it is employed, the more efficacious in general it will prove. It fortunately happens, that, in this complaint, the advantages of general and local blood-letting may be combined; inasmuch as a large quantity of blood can usually be procured from the vessels immediately connected with the inflamed organ. When this advantage can be obtained, it should never be overlooked. It is advisable, therefore, to open the temporal artery, or the jugular vein, and to take a large quantity of blood, according to the violence of the symptoms, and to the age and strength of the patient. Some authors recommend the opening of the artery, and some (especially Dr. Cullen and Hoffmann) prefer the section of the jugular vein. The frantic state of the patient sometimes renders either of these operations difficult, otherwise perhaps the choice is of little importance. We have seen a few instances, in which a free bleeding from the temporal artery was followed by the most speedy and permanent relief, where the *phrenitis* had followed intoxication and a metallic poison. Dr. M'Bride recommends that the blood-letting be carried to the extent of producing syncope or fainting; and when that effect follows, the relief is perhaps more generally complete; it is, however, rather a precarious rule of practice, and most practitioners prefer the safer mode of repeating the blood-letting at a short interval, than pushing it so far.

The effects of the blood-letting, in diminishing the morbid determination of blood to the head, should be seconded by all other means in our power. The application of cold to the scalp, such as washing it, after shaving, with cold water, vinegar and water, or with æther and spirits, (which last produce a great degree of cold by their rapid evaporation) is often exceedingly beneficial. To assist in lessening the flow of blood to the head, the patient should be kept as near the erect posture as can be borne. At the same time, every irritation, especially those of light and noise, of which the inflamed sensorium becomes peculiarly susceptible, should be carefully withdrawn. Some writers, especially of the old school, have recommended warm bathing to the lower extremities, and the application of blisters and rubefacients to them, for the purposes of revulsion. But Dr. Cullen justly regards them as very ambiguous remedies, which are likely to be productive of injury by increasing the general excitement of the circulation. It has been proposed to immerse the trunk and limbs in the warm bath, while cold applications are made to the head; a practice of which the theory is ambiguous, and a sufficient experience has scarcely been obtained to warrant the recommendation. *Blisters* have been generally applied over the shaven scalp, after the excitement has been somewhat reduced by blood-letting; but, on the whole, the active abstraction of heat, by means of the cold and evaporating fluids, above-mentioned, seems to afford a more decided relief.

In addition to these direct means of diminishing the inflammatory action in the head, the indirect effect, which is produced by copious evacuations from the bowels, obtained by the use of *purgatives*, is of great importance, and should be carefully attended to. Even syncope itself has been produced by profuse evacuations from the intestines, which implies the complete influence over the circulation in the brain, which such operations produce. The free use of cathartic medicines, therefore, should be resorted to in all cases of *phrenitis*; and if a spontaneous diarrhœa should supervene, the practitioner will be careful not to check it.

As in all other cases of inflammatory fever, every external source of excitement should be carefully excluded; the apartment should be cool and well ventilated; the bed-clothes light; the food liquid and chiefly of milk and farinaceous matters; the drink aqueous, cold, and acidulated. Antimonial and neutral diaphoretics may be exhibited as medicine, with the view of keeping a soft and moist state of skin, and diminishing febrile action.

When phrenitis occurs as a secondary affection in common fever, or by metastasis, it seldom assumes that violent character which idiopathic phrensy puts on; and consequently it demands a less vigorous treatment. Nevertheless the principles of the treatment must be the same. The removal of the determination of blood to the head must be attempted by the same measures, used in a more moderate degree. Thus the more local evacuations, such as bleeding by leeches applied to the temples, by cupping and scarifying the neck, and the application of cold, and of blisters to the shaven scalp, must be resorted to, and repeated according to the violence of the symptoms. The bowels should be evacuated by moderate cathartics, and similar diet and regimen should be adhered to as in the more acute species. And it should be cautiously observed, that, even should symptoms of typhoid fever supervene, yet while there is evident congestion in the brain, with flushed face, ferrety eyes, delirium, or coma, wine and all other stimulants must be withheld, as having a direct tendency to aggravate the symptoms, and to accelerate the fatal termination of the disease. See FEVER. See Wilson on Febrile Diseases, vol. iii. chap. 6. Cullen's First Lines.

PHRENSY, a violent delirium, originating from inflammation of the brain. See PHRENITIS.

PHRETOMANORUM URBS, in *Ancient Geography*, a town of Italy, in Samnium, of which Q. Fabius took possession, according to Diodorus Siculus.

PHRICODES, from *φριξω*, horror, shivering, in *Medicine*, a fever described by the ancients, of a remittent, semitercian form, in which the paroxysms are not only ushered in by shiverings, but accompanied by them through the greater part of their duration. See Galen, Comment i. in lib. i. Epidem.

PHRIDIESGAM, in *Geography*, a town of Russia, in the government of Viborg, on the N. coast of the gulf of Finland; 60 miles W. of Viborg. N. lat. 60° 35'. E. long. 26° 34'.

PHRIXIUM, in *Ancient Geography*, a town of Asia, on the confines of the Colchide and Iberia, according to Strabo; who says that, in his time, it was called Ideessa, and that it was well fortified.

PHRIXUS, a town of Asia Minor, in Lycia. Steph. Byz.—Also, a port of Asia, in the Thracian Bosphorus, near its mouth in the Euxine sea. Steph. Byz.—Also, a river of the Peloponnesus, in Arcadia, which received the waters of the Erasinus, and ran into the sea between Temenium and Lerna, according to Pausanias.

PHROLICHINO, in *Geography*, a lake of Russia, in the government of Irkutsk; 60 miles N. of Bargazinik.

PHRONTIS, a word used by Hippocrates as the name of a peculiar disorder of the general nature of the melancholy affections. In this case the patient, he says, feels, as it were, a thorn pricking the abdominal viscera; he is extremely restless and uneasy, and always avoids light and company. He dreads being touched, and becomes timorous and afraid of every thing; he is molested with troublesome dreams, and imagines that he frequently sees spectres and frightful objects.

PHRUGUNDIONES, in *Ancient Geography*, a people

of European Sarmatia, near the source of the Viistula, between the Sulones and the Avarini. Ptolemy.

PHRURÆSUM, mountains of Africa, in the interior of Mauritania Cæfariensis, S.E. of the mountains Malathubolus. Ptolemy.

PHRURI, a people of Scythia, in the vicinity of the Caspian sea.

PHRURIUM, a promontory on the S. coast of the isle of Cyprus, near Curtum, and N.E. of the promontory Curias. The term denotes a fortress.—Also, a town of India, on this side of the Ganges, placed by Ptolemy in the interior of the territory belonging to the Arvarni.

PHRYGANEÆ, in *Entomology*, a genus of insects of the order Neuroptera. The generic character is, mouth with a horny short curved mandible; four feelers; three stemmata; the antennæ are setaceous, longer than the thorax; wings equal, incumbent, the lower ones folded. There are fifty-five species, divided into two sections. The genus Phryganeæ consists of insects, which, in point of habit or general appearance, bear a considerable resemblance to some of the PHALENÆ, (which see,) and particularly to those belonging to the division entitled Tineæ. They may be distinguished from moths by their feelers, as well as by the stemmata situated at the top of the head. The Phryganeæ proceed from six-footed aquatic larvæ of a lengthened shape, residing in tubular cases, which they form by agglutinating various fragments of vegetable substances, particles of gravel, &c. These cases are lined within by a tissue of silken fibres, and are open at each extremity. The included larvæ, when feeding, protrude the head and fore-part of the body, creeping along the bottom of the waters which they inhabit by means of six short and slender legs; on the upper part of the back, in most species, is situated an upright papilla or process, serving as a kind of prop or stay, preventing the case from slipping too forward during the time the animal is feeding. The perfect insects are seen in a summer's evening floating in the air in large masses, and are eagerly devoured by swallows. The Phryganeæ are easily distinguished from the smaller moths by their wanting the spiral tongue.

A. Tail with two truncate Bristles.

Species.

MARGINATA. Wings immaculate; body brown, with yellowish spots on the head, sides of the abdomen yellowish. It is a large insect, and found in Germany. The thorax is grooved on the back; bristles of the tail yellowish, annulate with brown, and as long as the abdomen.

* BICAUDATA. Wings reticulate; body brown, with a yellowish line on the head and thorax. It inhabits this country and other parts of Europe.

* NEBULOSA. Wings pale cinereous; body brown. It inhabits also this and other countries in Europe.

VRIDIE. Wings greenish-hyaline, immaculate; body greenish. This is a small insect, and inhabits Germany. The antennæ are green tipped with black; the head and thorax are green, the latter faintly margined with black; the abdomen and legs are greenish.

B. Tail without Bristles.

Species.

* RETICULOSA. Wings sub-ferruginous, reticulate with black; body black. An inhabitant of Europe, as is also the next.

* STRIATA. Wings testaceous, with darker nerves.

PHRYGANEÆ.

ANALIS. Wings brown, with a white spot near the tail; the nape is covered with golden hair. Found in Sweden.

* **FUSCA.** Upper wings brown, immaculate; legs yellow. An inhabitant of this and other countries in Europe.

DISCOIDES. Wings brown, with a pale margin, and spots on the disk; the body is grey. It is found in Germany.

PILOSA. Wings testaceous, immaculate; the head and thorax hairy. This is a Swedish insect.

PALLIPES. All the wings black, immaculate; the legs are pale. A native of Italy, and is very small.

SIGNATA. Wings grey, spotted with yellow, the hind margin is striate with yellow.

* **GRANDIS.** Wings brown-testaceous, with cinereous spots. This is one of the largest of the European phryganæ, usually measuring an inch or more in length, and having very much the general aspect of a phalæna; the upper wings are grey, marked by various darker and lighter streaks and specks, and the under wings are yellowish-brown and semi-transparent. The larva, which measures nearly an inch and three-quarters in length, is of a flesh-coloured grey, with brown head and legs, and inhabits a tube composed of pieces of bark, small fragments of grass-stalks, or other substances. Like other larvæ of this genus, it is known by the name of *Cadew-worm*, and is frequently used by anglers as a bait. When arrived at its full growth it fastens the case or tube to the stem of some water-plant, or other convenient substance, in such a manner as to project a little above the surface of the water, and casting its skin, changes to a chrysalis of a lengthened shape, and displaying the immature limbs of the future phryganeæ, which in the space of a fortnight emerges from its confinement.

* **VARIA.** Wings varied with dark-grey and black, and spotted with white in the middle. This has been described and figured by Mr. Donovan. The legs are testaceous, and annulate with black.

IRRORATA. Wings grey-brown, with numerous whitish spots and specks. It is found in South America. A specimen of it is in Sir Joseph Banks's museum.

* **PHALÆNOIDES.** Wings white, with scattered black spots; the body is black. It inhabits the northern parts of Europe.

FLAVICORNIS. Wings grey; abdomen greenish; antennæ and legs yellowish. It inhabits Kiel.

* **RHOMBICA.** Wings grey-brown, with rhombic whitish spots. This is a much smaller species than the *grandis*, and is of a yellowish-brown colour, with two obliquely transverse rhomboidic semi-transparent white spots on each upper wing; the lower wings being whitish, with a tinge of yellowish-brown towards the upper edge. The larva is of a greenish-brown colour, and like that of the *grandis* is found in rivulets and stagnant waters. The larvæ of the phryganæ in general feed not only on the smaller water insects, but on the spawn of fishes, and even on the young fry itself.

* **GRISEA.** Upper wings clouded, with a black marginal spot. This is found in England and other European countries.

ATOMARIA. Wings pale-grey, with numerous black dots. This is a native of Kiel; is rather a large insect; the antennæ are yellowish; the head and thorax hairy; the body cinereous.

FENNICA. Wings striate, cinereous, with a testaceous dot near the tail; the body is black; the antennæ are white at the base. It inhabits Denmark. The antennæ of this species are black at the tip.

ATRATA. Black; wings immaculate; antennæ short. It inhabits France. The body is villous.

NOTATA. Upper wings yellowish-grey, with a brown marginal spot. It inhabits North America. A specimen is in the museum of Sir Joseph Banks.

* **BIMACULATA.** Wings brown, with a double yellow lateral spot. It inhabits Europe. The larva is found in a tapering cylinder, composed of sand and mud.

* **NIGRA.** Wings black; antennæ twice as long as the body. It is found in the northern parts of Europe, as is the next.

* **AZUREA.** Wings black; the hinder part violet. The lower wings are likewise obliquely violet.

VARIEGATA. Wings brown, speckled with testaceous. It is found in divers parts of Germany.

* **BILINEATA.** Wings brown, with two transverse white lines on each margin. It inhabits northern Europe.

* **INTERRUPTA.** Wings black, with four white bands, the anterior ones are interrupted, the hind one is marginal and composed of dots. This is a native of our own country, as is the next. The body is black.

* **HIRTA.** Brown; upper wings hairy; antennæ as long as the body. The antennæ are white, annulate with brown.

* **LONGICORNIS.** Wings brown, with two darker waved streaks; antennæ are very long. It is found, as well as the next, in this country and other parts of Europe.

* **QUATUOR-FASCIATA.** Black; wings testaceous, with four black bands; antennæ very long.

PUNCTATA. Wings fringed, pale-yellowish, dotted with white; the abdomen is green. It is a native of Paris, and very much resembles a moth.

* **FILOSA.** Wings rounded, brown, immaculate; antennæ thrice as long as the body. This is a native of England.

TRI-PUNCTATA. Wings fringed, cinereous, with three brown dots. It inhabits Saxony. The antennæ are longer than the body.

* **MINUTA.** Variegated with brown and cinereous; feelers villous. It inhabits Europe.

PUSILLA. Wings fringed, brown-testaceous; antennæ moderately long, annulate with white and black. It is a native of Italy.

ATRATA. Black; wings whitish, with numerous black spots, and two bands. It inhabits Siberia.

CILIARIS. Black; abdomen with a white line on each side; the hind shanks paler; antennæ moderate. It is found in various parts of Europe, but not in England.

WENERI. Cinereous; lower wings paler, the inner margin whitish and hairy. It inhabits Sweden, as does the next.

ALBIFRONS. Black; wings with four white linear streaks on the outer part.

FLAVA. Wings reticulate with yellow; antennæ moderately long. This and all the following are found in some or other of the countries of Europe.

UMBROSA. Black; upper wings with yellowish clouds.

SALTATRIX. Wings hyaline, with a green and white spot; the antennæ are longer than the body.

VIRESCENS. Wings white, with ferruginous spots at the future, and inflected margin; abdomen greenish; legs yellowish.

ARGENTATA. Wings varied with brown and silvery, with a brown dot behind the middle at the anterior margin, and three at the posterior; the lower ones tipped with brown.

FASCIATA. Wings pale-yellow, with four white bands, one entire, the others composed of spots.

STRIGOSA.

STRIGOSA. Testaceous; lower wings with a long white streak towards the tip.

MACULOSA. Wings brown, hairy, spotted with white, two of the spots solitary towards the tip at the outer margin.

LACINIOSA. Testaceous; wings with three white bands united at the base, and each divided at the tip, with an oblique spot in the middle.

ATOMARIA. Testaceous; wings grey, with numerous whitish solitary and confluent dots.

TESTACEA. Wings and body brown-testaceous; lower ones whitish.

INCONSPICUA. Brown; antennæ and fore-feelers long; wings grey, glabrous at the tip; legs yellowish.

CILIATA. Black; wings subtestaceous, fringed, the veins at the margin very much branched, the four fore-legs testaceous.

ANNULATA. Brown; antennæ long, annulate with white; wings fringed at the inner and hind margins.

PHYRGANICUS, in *Botany*, a term used by Dioscorides, and many other of the ancient Greeks, to express such herbaceous plants as have hard and woody stalks; such are the garden-thyme, and several others of that kind. They also call these plants *xylodes*, ξυλωδες, and ξυλωδεῖα ποτα.

PHYRGES, or **PHYRYX**, in *Ancient Geography*, a river of Asia Minor. It discharged itself into the Hermus, gave its name to Phrygia, and separated this province from Caria, according to Pliny.

PHYRYGI, a people of Illyria, in the vicinity of the Ceraunian mountains. Strabo.

PHYRGIA, a country of Proconular Asia, concerning the name of which there are two different opinions: the one ascribing it to the country, whence it passed to the people; and the other attributing it to the people, who gave it to the country. According to the former opinion some have derived it from the river Phryges or Phryx (now Sarabat;) others from Phrygia, the daughter of Afopus and Europa, an etymology which is founded in mere fable. Bockart supposes, that this tract was called Phrygia from the Greek verb φρυγισιν, to burn or parch, which, according to him, is a translation of its Hebrew name, derived from a verb of the same signification. This etymology bears relation to the nature of its soil, which was dry in many parts of it, and which, in its mountains, exhibited traces of volcanos. Another opinion ascribes the name of Phrygia to Phryges, the people who inhabited it; and it is said that they had at a former period borne the name of Bryges or Breges; and these, according to Strabo, were the same people: Herodotus says, that whilst they remained in Europe they were called Breges, but after their passage to Asia, their name was changed into Phryges.

With regard to the boundaries of Phrygia, Strabo informs us, that those of the Phrygians and Mysians were distinct; but that it was scarcely possible to ascertain them. He adds, that the Trojans, Mysians, and Lydians, are all, by the poets, blended under the common name of Phrygians, which Claudian extends to the Pisidians, Bithynians, and Ionians.

Phrygia Proper, according to Ptolemy, was bounded on the north by Pontus and Bithynia; on the west by Mysia, Troas, the Ægean sea, Lydia, Mæonia, and Caria; on the south by Lycia; and on the east by Pamphylia and Galatia. It lies between the 37th and 41st degrees of N. lat., extending in longitude from 56 to 62 degrees. Phrygia is commonly divided into the *Greater* and *Lesser*, called

also Troas; but this division did not take place till Troas was subdued by the Phrygians; and hence it is more considered by some Roman writers as a part of Phrygia, than Bithynia, Cappadocia, or any other of the adjacent provinces. In subsequent ages, the Greater Phrygia was divided into two districts or governments, one called Phrygia Pacatiana, from Pacatianus, who, under Constantine, bore the great office of the præfectus prætorio of the east: the other Phrygia Salutaris, from some miraculous cures said to have been performed there by the archangel Michael.

This country, as well as the whole of Asia Minor lying in the 5th and 6th northern climates, was, in ancient times, highly celebrated for its fertility. It abounded in all sorts of grain, being, for the most part, a plain country covered with a deep rich soil, and plentifully watered by small rivers. In some parts it furnished bitumen and other combustible substances. Having large plains and pasture grounds, it was well stocked with cattle. The air was anciently deemed very pure and salubrious, though it is now, in some parts, thought to be extremely gross, as a great part of the country lies in an uncultivated state. The most remarkable cities in Phrygia Major were the following, viz. Apamea or Apamia, the metropolis of all Phrygia, till the above-mentioned division of Constantine took place: this is commonly called Apamea Cibotos.—Laodicea, now Eskihissar, seated on the banks of the river Lycus, not far from Apamea; the inhabitants of which carried on a very considerable trade in wool, which was much admired for its softness, and who were reckoned the most wealthy people in Asia Minor. Laodicea was one of the seven churches mentioned in the Apocalypse; but at present only its ruins are to be seen. At Eskihissar, as it is now called, there are still to be seen four theatres of white marble, as entire as if they had been lately built; near one of them is an inscription in honour of the emperor Titus.—Hierapolis, famous for its mineral waters, which, according to Strabo, when exposed to the air, petrified in the space of a year, and yet possess such a virtue as to render the fields watered by them to be exceeding fruitful, and to afford a present remedy against innumerable distempers. Near this city was a deep cavern, which was always overspread with a thick fog, and which exhaled such a pestilential stream, that it stifled any living creature who approached it. Strabo and Pliny except the Galli or eunuchs of Cybele; Ammianus and Dio Nicæus except all eunuchs. Hierapolis is now called Bambuk-kalasi, and some vestiges of its ancient magnificence may be still seen in heaps of ruins and fine pillars.—Gordium, situated on the borders of Phrygia towards Cappadocia.—Colosse, now Chonos, on the S. side of the Meander.—Sipyilus, the residence of king Tantalus, and hence called Tantalus.—Synnada, noted for its marble quarries; built by Constantine the Great, and declared the metropolis of Phrygia Salutaris, after his division took place. Besides these, and other cities of less note, there were some in later times of no small account; such as Saqua, Chara-Chifar, Cillexuga, Einegiol, &c. taken by the Ottomans from the Christian princes, at the first rise of the Ottoman empire.

The rivers of this country are the Mæander, now Madre or Mendre, which rises in the hill Celænæ, passes through Phrygia, divides Caria from Lydia, and after, as it is said, 600 windings, by which it seems to flow back to its fountain-head, empties itself into the Archipelago between Priene and Miletus.—Marsyas, rising near or at the spring of the Mæander, and rushing down from a considerable height between rugged rocks, and after flowing through the town of Celænæ, in the same channel with

PHRYGIA.

the Mæander, separating into two branches, which form these two rivers; Marfyas pursuing a direct course with an incredible rapidity, and near Apamea being again received into the Mæander. Sangarius or Sangaris, springing from the hill Dindymus, washing Phrygia and Bithynia, and discharging itself into the Black sea.—Phryx or Phryges, (which see).—Hermus, celebrated by the poets for its gold sands, which rises near Dorylæum, and falls into the Archipelago near Smyrna.—Myſias, Orga, OIrima, &c.

The Phrygians claim high antiquity; but their origin is uncertain. Josephus and St. Jerom suppose that they are descended from Togarmah, one of the sons of Gomer. Herodotus, Strabo, Pliny, and Eustathius deduce their origin from the Brygians, a people of Macedonia, who, passing into Asia Minor, were called Phrygians. Bochart agrees with those who trace their origin to Gomer, the eldest son of Japhet. Whatever was their origin, they were superstitious, voluptuous, and effeminate, without prudence, and so fervile in their temper, that they could be induced to comply with their duty only by stripes and ill usage. This character, under which they are described, gave rise to several trite and well-known proverbs: "Phryges sero sapiunt;" "Phryx verberatus melior;" &c. Their music was suited to their effeminate temper, and tended, as some have said, to enervate the mind. The Phrygians are said to have been the first inventors of divination by the singing, flying, and feeding of birds. Their government was monarchical, and they were for some time under one sovereign. But some time before the Trojan war, this country was divided into several petty kingdoms, and several princes reigned at the same period. Apollodorus mentions a king of Phrygia, who was contemporary with Ilus, king of Troy. Cedrenus and others speak of Teuthrans, king of a small part of Phrygia, whose territories were ravaged by Ajax, and his daughter Tecmessa carried away captive by the conqueror. Homer mentions Phorcyas and Afcaneus, both princes and leaders of the Phrygian auxiliaries, that came to the relief of Troy. Tantalus was king of Sipylus, and he is said to have been no less famous for his great wealth, than infamous for his avarice, and other detestable vices. It is also reported, that with a view of appeasing internal discords, the Phrygians consulted an oracle, which directed them to commit the government to a king; upon which they placed Gordius on the throne.

As to their commerce, we merely know, that Apamea was the chief emporium of all Asia Minor, which was the place of resort for merchants and traders from all parts of Greece, Italy, and the neighbouring islands. From Syncellus we also learn that the Phrygians were for some time masters of the sea, and none but trading nations ever prevailed in that element. The country produced many rare and useful commodities, which afforded considerable exports. They had a safe coast, convenient harbours, and other advantages which warrant our concluding that they carried on a considerable trade. Of their laws we have no knowledge; and in favour of their learning it may be alleged, that, as they enjoyed the sovereignty of the sea, they must have had a competent skill in geography, geometry, and astronomy; to which we may add that they had a more than ordinary knowledge of music.

It has been the opinion of some writers, that the Phrygian language bore a great resemblance to the Greek, but others have alleged to the contrary. The few Phrygian words which have been transmitted to us, are carefully collected by Bochart and Rudbeckius. Strabo also says, that it is difficult to discover any similitude between the barbarous

words of the Phrygian language and the Greek. The Egyptians looked upon the Phrygian tongue as the most ancient language of the world: but other nations, and particularly the Scythians, will not admit this fact.

The ancient Phrygians were much addicted to superstition. They had many idols: but their principal deity seems to have been Cybele. (See CYBELE.) They also worshipped several other idols, viz. Bacchus, Adagyus, and the Cabiri. In solemnizing the festivals of their gods, and on other occasions, they had dances and songs, which they called "lityerfes," from Lityerfes, son of Midas, king of Phrygia. Hefychius mentions certain Phrygian dances, called by him "bricigmata," derived without doubt from the word Bryges, the ancient name of the Phrygians.

The kings of Phrygia whose names are recorded were, Nannacus, Annacus, or Cannacus, who is the first king mentioned in history, Midas, Marcis, Gordius, Gordius II., Otreus, Lityerfes, Midas II., Gordius III., Midas III., and Midas IV., with whom ended the royal family of Phrygia, which became a province of the Lydian monarchy, and continued in that state till Cræsus was conquered, and all Lydia was reduced by Cyrus.

PHRYGIA *Minor*, or *Lesser Phrygia*, was divided into two parts, the maritime, called "Helleſpontica," and the Mediterranean, termed "Epiçtetus." The former borrowed its name from the Helleſpont, and extended along the coast from the town of Percote to the promontory Lectum or Lecton, opposite to the N. side of the island of Lesbos. This part was properly called Troas, or Troia, though the Trojan kingdom extended from the river Afopus, to the banks of the Caicus, including not only Troas, but also the greater and lesser Myſia. Epiçtetus, or the inland part of Phrygia Minor, extended to the neighbourhood of mount Olympus, in the greater Myſia. This part at first belonged to Prusias, king of Bithynia, who yielded it, by agreement, to Eumenes, king of Pergamus, whence it was called Epiçtetus, that is, acquired. However, these appellations are frequently confounded, and both attributed to Phrygia Minor.

Phrygia Minor lay between the 40th and 42d degrees of N. lat., and in longitude was of small extent. In general it may be said, that Phrygia Minor, as comprehending both the Helleſpontica and Epiçtetus, was bounded by the Propontis on the N., by the Ægean sea on the S., by Myſia Minor on the E., and the Helleſpont on the W. On the sea-coast were the cities of Percote, Abydus, Aſiaba, Dardanum, Rhetum, Sigeum, Troy or Ilium, Lariffa, Colonzæ, Alexandria, and Troas.

Of the rivers that watered Troas, or Phrygia Minor, we need only mention the Scamander and Simois, which see respectively. The only mountain of this country that deserves notice was mount Ida, being a ridge of hills extending from the city of Zeleia, near the borders of Myſia Minor, to the promontory Lectum.

The soil of this district was anciently reckoned extremely fertile; and it has even now signs of fertility, though in a great measure neglected and uncultivated. Modern travellers describe the Asiatic coast of the Helleſpont, as a most beautiful and fertile tract of land; the hills being covered with vineyards and olive plantations, and the vales productive of all sorts of grain.

The inhabitants of Lesser Phrygia, or Trojans, so called from Troy, the metropolis of that country, were undoubtedly a very ancient people; but authors are not agreed about their origin. Some represent them as by descent Samothracians; others say they were Greeks; some again derive them from the island of Crete, whence they suppose Phrygia

Minor

Minor to have been peopled; others say, that they were descended from the Arcadians, and there are writers who maintain that they originally came from Italy, in which opinion Virgil concurs.

Bochart thinks that Lesser Phrygia was planted by Ashkenaz, Gomer's eldest son, because some appellatives of lakes, rivers, islands, cities, and men of that country, bear a resemblance to this name. But the blood of the first inhabitants of this country, whoever they were, was mixed in process of time with that of foreigners, namely, of Myrians, Samothracians, Greeks, and Cretans, who settled among them, and were reckoned of the same descent with the ancient proprietors.

As to their government, it was unquestionably monarchical and hereditary; for from Dardanus to Priam, the father was constantly succeeded by the son, or the elder brother by the younger. Their country was at first parcelled out into several small kingdoms: but the sovereigns of all these were, in length of time, either expelled or made tributary by the Trojan kings; inasmuch that Strabo enumerates nine small kingdoms, or principalities, subject to Troy, besides the island of Lesbos. On this account the Trojan war was so protracted; because all these countries were to be subdued before Troy could be invested. Of their laws no particular system remains. Their religion was substantially the same with that of the inhabitants of Greater Phrygia. Their principal deities were Cybele, "the grand-mother of the gods," as they styled her, Apollo, Minerva, and Pallas, (see PALLADIUM,) Venus, and Apollo Sminthius. The Trojans are celebrated as one of the most polite and civilized nations of those days; and in the reigns of their later kings they rose to a very considerable pitch of splendour and magnificence. Their language was probably the same that was spoken by the inhabitants of Greater Phrygia. Their trade can only be guessed at from their situation, which probably drew merchants from all the neighbouring parts to traffic in their country, as well for their own growth as for foreign productions. Their country abounded with the necessaries of life, as we may conclude from their having supported two very considerable armies for many years. Their settlements in Thrace, Peloponnesus, Sicily, Italy, Egypt, and Africa, afford sufficient proof, that they applied themselves at an early period to trade and navigation, which, most probably, were the sources of the riches, splendour, and power, in which they far excelled all the neighbouring states.

Troas, or Phrygia Minor, was, in all probability, governed by kings before the reigns of Teucer and Dardanus; but the Trojan history of that period is either fabulous or uncertain. Teucer, as some say, was the first sovereign; he was the son of Scamander and Ida, that is, born in Phrygia, near the river Scamander and mount Ida, and ruled over all Troas, or Phrygia Minor. From him the country was called Teucra; and the inhabitants were denominated Teucris. He was succeeded by Dardanus, who extended the boundaries of his kingdom by considerable acquisitions, and built two cities, one called Dardana, or Dardania, from his own name, and the other Thymbra, from Thymbraeus, one of his intimates. Having reigned in Phrygia 64 or 65 years, he was succeeded by his son Erichthonius, who after a long, honourable, and prosperous reign of 46, as some say, or according to others, 75 years, left the kingdom of Phrygia in a flourishing condition. Tros, the founder of Troy, was his successor, from whom Phrygia Minor borrowed the name of Troas, as its metropolis did that of Troy. He was succeeded by his son Ilus, who drove Tantalus out of Asia, and annexed his kingdom

to the crown of Phrygia; and having enacted many useful laws for the regulation of public affairs, he died in the 40th year of his reign. On the death of Ilus, his son Laomedon was placed on the throne; he built the citadel of Troy, but having treated Jason and the Argonauts, who had landed on the coasts of Troy, in an inhospitable manner, Hercules, who was one of them, avenged their cause by taking Troy, and afterwards killing Laomedon. Podazers, his only surviving son, was his successor. In his reign happened the war which terminated in the capture of Troy, which see; the city of Troy being utterly ruined, and most of the inhabitants of Troas put to the sword. Some writers say, that the neighbouring Phrygians and Lydians possessing themselves of that country, settled there; and that Troas from that time began to be called Phrygia; others are of opinion, that Æneas, having gathered together the scattered remains of the Trojans, rebuilt the city; and that his descendants, and the descendants of Hector, reigned there till the country was subdued by the Lydians, who became so powerful as to over-run all Asia Minor. If the Trojans had any kings of their own, after their city was destroyed by the Greeks, they probably made but an indifferent figure, since they are not even named in history. Anc. Un. Hist. vol. iii.

PHRYGIAN MODE, in *Music*. See *Grecian MODE*. This mode and its effects are so frequently mentioned in ancient authors, that we must collect into a point its pretended properties. The Phrygian mode is one of the principal and most ancient modes of the Greek music. Its character was ardent, fierce, impetuous, vehement, and terrible. So that, according to Athenæus, trumpets and other military instruments, founded in the Phrygian mode. All this, however, might be said of our trumpets in sounding the charge, signals of battle, and even in playing marches; and that our kettle-drums and side-drums are beaten in the Phrygian mode; in which all music seems at present transposed by the eternal din of double drums and trumbone.

PHRYGIAN Stone, *Phrygius Lapis*, in *Natural History*, the name of a stone described by the ancients, and used in their time in dyeing; probably from some vitriolic or aluminous salt contained in it, which served to enliven or fix the colours used by the dyers.

It was a light spongy mass, resembling a pumice, and the whitest and lightest were esteemed the best. Pliny gives us an account of their preparing it for use for dyeing, which was by moistening it with urine, and then heating it red-hot, and suffering it to cool again: this calcination was repeated three times, and the stone was then fit for use; and Dioscorides recommends it in medicine after burning; he says it was drying and astringent.

PHRYGIANS, **PHRYGES**, or **PHRYGASTES**, as St. Epiphanius calls them, in *Church History*, were a branch of the Moataniits; so called from Phrygia, a country where they abounded.

They esteemed Montanus their prophet; and looked on Maximilla and Priscilla as great prophetesses.

This spirit of prophecy, or rather enthusiasm, was their distinguishing character. See **CATAPHRYGIANS**.

PHRYMA, in *Botany*, a Linneæan name, whose meaning or derivation nobody has ventured to guess, nor can we throw any light upon the subject. Linn. Gen. 303. Schreb. 399. Willd. Sp. Pl. v. 3. 179. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 431. Juss. 117. Lamarck Illustr. t. 516. Gærtn. t. 75. (Leptostachia; Mitchell Eph. Nat. Cur. v. 8. 212.)—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Personate*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cylindrical,

drical, striated, gibbous at the base on the upper side, two-lipped; its upper lip narrow, and longest, with three awl-shaped converging teeth; the lower obtuse, cloven. *Cor.* of one petal, ringent; tube the length of the calyx; upper lip shortest, nearly ovate, emarginate, straight; lower larger and more spreading, three-cleft, the middle segment most prominent. *Stam.* Filaments four, two at each side, the upper ones shortest; anthers roundish, approximated, in the throat of the corolla. *Pist.* Germen oblong; style thread-shaped, the length of the stamens; stigma obtuse. *Peric.* none, except the permanent, furrowed, closed calyx. *Seed* solitary, oblong, nearly cylindrical, with a furrow at one side.

Ess. Ch. Calyx two-lipped, five-toothed. Seed solitary.

1. *Ph. leptostachya.* Slender-spiked Phryma. Linn. Sp. Pl. 838. Suppl. 277. Amoen. Acad. v. 3. 19. (Circææ foliis, amaranthi sculi Boccone spicâ, floribus parvis purpureis propendentibus, herba Florida; Pluk. Amalth. 59. t. 380. f. 5.)—Leaves ovate, serrated. Calyx of the fruit deflexed.—Native of close woods in North America; “from Canada to Carolina.” *Mitchaux.* It is said to have been sent to Kew in 1802, by the late Mr. Masson, and is marked as a hardy perennial, flowering in July and August. The herbage resembles a *Verbena* or *Veronica*, and the flowers, disposed in long slender terminal spikes, are too small and unattractive to obtain much favour. It is to be wished however that a good figure of so little known a plant and genus might be given to the public.

2. *Ph. debilescens.* Splitting Phryma. Linn. Suppl. 277. Willd. n. 2. (Buchnera cuneifolia; Linn. Suppl. 288. Willd. Sp. Pl. v. 3. 335. Thunb. Prodr. 100.)—Leaves wedge-shaped, sharply toothed at the summit. Calyx of the fruit erect, splitting lengthwise. Gathered by Thunberg at the Cape of Good Hope. (See *BUCHNERA.*) The younger Linnæus was not aware of having mentioned this plant under two different names, in his *Supplementum*, nor did Willdenow detect the mistake, though he justly objected to its being a *Phryma*. We must rely on Thunberg's authority in supposing it a *Buchnera*. The stem is shrubby, much branched, of humble growth. Leaves opposite, stalked, wedge or fan-shaped, fleshy, rough with minute points or bristles; terminating in about seven strong sharp teeth. Clusters terminal, solitary, simple, three or four inches long, of numerous flowers, which Linnæus the elder has very carefully described on his specimen before us, as follows. “Calyx of one leaf, cylindrical, with five angles; abrupt, with five teeth; finally splitting along one side. Corolla of one petal; tube cylindrical; limb in five, nearly equal, small, rounded segments. Stamens two long and two short. Germen superior, oblong; style short; stigma simple. Seed (rather capsule) almost as long as the calyx, obscurely quadrangular, compressed, smooth, rugged in the upper part; abrupt at the base; of two cells. Seeds solitary, somewhat club-shaped.” The fewness of the seeds is the chief objection to our considering this plant as an indubitable *Buchnera*. Perhaps it ought to constitute a new genus, but its habit closely agrees with the Linnæan *Buchnera cernua*, an imperfect specimen of which is actually laid into the Linnæan herbarium as a nondescript *Phryma*. We are unacquainted with the number of its seeds.

PHRYNICUS, surnamed *Arbafus*, in *Biography*, a Greek sophist or orator, was a native of Bithynia, and flourished in the reigns of Marcus Antoninus and Commodus. Two works are attributed to him, viz. “Apparatus Sophisticus,” and “Dictiones Atticæ.” There is extant an abridgment of the latter, which was printed at Rome, with the title of “*Eclogæ Nominum et Verborum Atticorum*,”

Gr. et Lat. 1517. The best edition of this work is that of Pauw in 1739. Of the same name were a composer of a tragedy, the disciple of Theopis, and a comic poet, who flourished about a century later.

PHRYNIUM, in *Botany*, a name borrowed by Willdenow from the ancient Greeks, whose *φρυνίον* was so called from *φρυνη*, a red kind of land toad, reputed venomous, to which the plant in question, being armed with spines, was thought to be hostile. Our *Phrymium* is a smooth herb, growing in damp shady places, and rather affording shelter to various reptiles, than dangerous to any. Willd. Sp. Pl. v. 1. 17. Rofcoe Tr. of Linn. Soc. v. 8. 341. (Phyllodes; Loureir. Cochinch. 13.)—Class and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Brown Prodr. Nov. Holl. v. 1. 307.

Gen. Ch. Cal. Perianth superior, of three awl-shaped, erect, equal leaves. *Cor.* of one petal, tubular; its limb in seven segments; the three outermost acute, nearly equal, reflexed; the four innermost obtuse, erect, unequal. Nectary a long, channelled, upright lip. *Stam.* Filament solitary, awl-shaped, short, united to the base of the nectary at one side; anther oblong, irregular, simple. *Pist.* Germen inferior, ovate, triangular; style thick, short, scarcely exceeding the stamen; stigma concave, bent towards the anther. *Peric.* Capsule bluntly triangular, of three cells. *Seed* solitary, ovate, smooth.

Ess. Ch. Calyx of three leaves. Inner segments of the corolla four, obtuse, unequal. Stamen awl-shaped. Anther simple. Style thick, short, inclined towards the anther. Capsule with one seed.

Obs. It appears by the descriptions of authors, for we have not seen the fruit or germen, that the latter is of three cells, with the rudiments of three seeds, only one of which comes to maturity. Yet Willdenow mentions “three nuts.”

1. *Ph. capitatum.* Willd. as above. (Phyllodes placentaria; Loureir. Cochinch. 13. Naru kila; Rheede Malab. v. 11. 67. t. 34.)—Native of moist shady places in Cochinchina China, and the coast of Malabar. Root perennial, knotty, creeping horizontally. Stem none. Leaves radical, on long, simple, upright smooth stalks four feet high, ovate-oblong, acute, entire, flat, smooth, coriaceous, a foot long, obliquely furrowed. Flowers white, in a large sessile hemispherical cyme, from a lateral cleft below the middle of the leaf-stalk, accompanied by two large bractæ, embracing several smaller ones, each common to many flowers. Loureiro observes that the germen is generally abortive, and that the leaves are used for wrapping up cakes, in the oven, to give them an agreeable taste as well as colour. The young unfolded leaves are infused in rum or arrac, with thrice as much water, to make vinegar.

This may perhaps not be the only species of its genus. We have two nondescript plants gathered at Sierra Leone, by Dr. Afzelius, which that excellent botanist judged to belong to *Phrymium*. Their inflorescence however seems to be terminal, and we are rather more inclined to refer them to *Thalia*, or perhaps *Maranta*.

PHRYNUM, in *Zoology*. See *RANA Bufo*.

PHTHALEON, in *Ancient Geography*, a town of Greece, upon the Pegasean gulf.

PHTHAS, in *Mythology*, a name given among the Egyptians to the Greek Vulcan, whom they considered as the Supreme Divinity, or at least as an attribute of that active principle, or intelligent power, eternally united, in their opinion, with the chaotic mass, by whose energy the elements were separated, and bodies were formed, and who continually presides over the universe, and is the efficient cause of all effects. For this we have not only the autho-

rity of Plutarch (Isis et Osiris), who may be suspected of having exhibited the Egyptian philosophy in a Grecian dress, but the united testimony of many writers, who give such accounts of the Egyptian gods, Phthas or Vulcan, and Cneph or Agathodæmus, as render it probable that these were only different names expressing different attributes of the Supreme Divinity. The Egyptians, says Eusebius, call the maker of the universe by the name of Cneph, and relate, that he sent forth an egg from his mouth; which in their symbolical language denotes that he produced the universe. (See CNEPH.) Diodorus Siculus (l. i.) speaks of the Egyptian Vulcan as the first king among the gods, and Manetho ascribes to him unlimited duration, and perpetual splendour. The name itself, Phthas, signifies, according to Jablonski, in the Coptic language, one by whom events are ordained, or the disposer of things. When the Egyptians mean to represent the ruler of the world as good, they called him by the appellation Cneph, denoting a good genius; and they represented him under the symbol of a serpent. Upon a temple dedicated to Neithas at Sais, the chief town in Lower Egypt, was this inscription; "I am whatever is, or has been, or will be, and no mortal has hitherto drawn aside my veil; my offspring is the sun." Plutarch and Proclus mention this inscription, though with some difference of language; and it is so consonant to the mythological spirit of the Egyptians, that notwithstanding the silence of more ancient writers, who treat of this theology, its authenticity may be easily admitted. If this be allowed, and if, at the same time, it be granted, as the learned Jablonski maintains (Pantheon Egypt.), that Neithas and Phthas were only different names for the same divinity, this inscription will be a strong confirmation of the opinion, that the Egyptians acknowledged the existence of an active intelligence, the cause of all things, whose nature is incomprehensible. On the obelisk of granite, transported from Egypt to Rome, amongst the hieroglyphics of which Hermaphion has given the interpretation, is the following remarkable passage, on the subject of Ramesses, king of Heliopolis: "This is he, whom Phtha, the father of the gods, has elected." These words, the father of the gods, point out the stars, which the Egyptian sages regarded as the most striking emblems of the divinity, and which the people really adored.

Upon the whole we may conclude, that Phtha was regarded, in remote antiquity, as the ordaining spirit, and the great architect of the universe. The inhabitants of Memphis raised a temple to him where he was principally worshipped. Herodotus and Diodorus Siculus have described this temple; and Suidas adds, the inhabitants of Memphis adore Vulcan under the name of Phtha. From Phtha we ought not to separate the god whom the Egyptians adopted under the name of Neith, since he also is the creating spirit. Neith, in fact, signifies, according to Jablonski, him who disposeth all things. By the first of these attributes, God was understood to be taken in a general sense, and by the second, his wisdom was particularly characterised. He had a temple at Sais; and Plato, who frequented it says, Neith, to whom the Greeks have given the name of Minerva, is its tributary deity. Neith and Phtha are therefore the same divinity. The Phœnicians, who received their religion and their knowledge from their brethren the Egyptians, likewise acknowledged Minerva, or Neith, for the artist of nature. Cadmus, the Phœnician, who carried this worship into Greece, gave the name of Neith to one of the seven gates of Thebes, in Bœotia; and there the Egyptian theology was taught. The Egyptians adoring the power of the creator under the name of Phtha,

and his wisdom under that of Neith, honoured his beneficence, by calling him Cneph, or good, by way of excellence.

In fine we may conclude, notwithstanding what has been advanced to the contrary by Porphyry, and others, that it appears highly probable, that the ancient Egyptians acknowledged an active as well as a passive principle in nature, and as Plutarch asserts, worshipped $\tau\omega\ \tau\epsilon\tau\alpha\rho\alpha\ \Theta\epsilon\omega$, the supreme deity. Brucker's Phil. by Enfield, vol. i. Savary's Travels in Egypt, vol. i.

PTHĒMBUTI, in *Ancient Geography*, a nome of Egypt, the capital of which was called "Tava" by Ptolemy.

PTHENOTES, a nome of Egypt, the capital of which was Butos. Ptolemy.

PTHIA, a port of Africa, in Marmarica, between the great Chersonesus and Paliurus.—Also, a town of Asia, in the vicinity of the Euxine sea.

PTHINTHIA, a town situated in the interior of Sicily. Ptolemy.

PTHIOTIS, a country of Greece, in Thessaly; it lay to the S.E. near Magnesia.

PTHIRA, or **PTHIRO**, a mountain of Asia Minor, in Caria. Steph. Byz. and Suidas.

PTHIRIASIS, $\pi\theta\iota\rho\iota\alpha\sigma\iota\varsigma$, in *Medicine*, from $\pi\theta\iota\rho\iota$, a louse, signifies the lousy disease, *morbus pedicularis*, and *pediculatio*, of authors.

Of these well-known insects, which infest the human body, there are two species; the one more commonly affecting the hairy scalp, and the other the pubes. Of the former species, however, (the pediculus humanus,) there is a variety usually termed body-lice, concerning which Linnæus remarks, "Varietas capitis durior, coloratio, vestimentorum laxior, magis cinerea." These pediculi are bred abundantly among the inhabitants of fordid dwellings, of gaols, and work-houses, &c. and in such situations prey upon persons of all ages indiscriminately. There is, however, also a peculiar state of skin in people advanced in years, and connected with the disease, which has been denominated Prurigo senilis by Dr. Willan, in which they are generated, notwithstanding every attention to cleanliness or regimen, and multiply so rapidly, that the patient endures extreme distress from their perpetual irritation. The nits or eggs are deposited on the small hairs of the skin; and the pediculi are only found on the skin or on the linen, and not under the cuticle, as some of the old authors have represented. Many marvellous stories, indeed, are related by Forestus, Schenckius, and others, respecting lice bred under the skin, and discharged in swarms from abscesses, strumous ulcers, and vesications; and many individuals of great note are stated to have died, in ancient times, from the multitude of these devouring pediculi. Thus Plutarch relates of Sylla: "It was long before he perceived that he had an ulcer within his body; but at last the flesh putrefied, and produced such a quantity of lice, that though many persons were employed day and night in destroying them, yet they increased much faster than they could be removed; and to such a degree did the distemper prevail, that his clothes, baths, basins, and food, were polluted with that perpetual flux of corruption and vermin. He went many times in the day into the water, to scower and cleanse his body, but all in vain; the vermin multiplied so fast as to baffle every attempt to destroy them." The biographer adds, "it is said, that among the ancients, there died of this disease Acastus the son of Pelias, and nearer our own times Alcæon the poet, Pherecydes the philosopher, Callisthenes the Olynthian, during the time of his imprisonment, and

Mutius

Mutius the lawyer: and if it be proper to add to these a person not distinguished by any merit or virtue, Eunus, a fugitive slave, who was author of the war in Sicily, called the "fervere war," and who was taken and carried prisoner to Rome, died likewise of this sickness." (See Plutarch's Life of Sylla; also, Plin. Hist. Nat. lib. xxvi. cap. 13, who, speaking of phthiriasis, observes, "quæ Sylla dictator consumptus est.") Herod, Ennius, and by some Plato is said also to have been destroyed by the lousy disease.—In more recent times, Amatus Lusitanus has affirmed, that he was witness to the case of a gentleman, who perished miserably in this disease: "for to universally did these insects swarm over his body, that two negro servants were entirely employed in collecting baskets full from his person, and carrying them to the sea." Amat. Lusit. Contur. iii. Cur. 58. See also Forest. Obs. Med. lib. viii. obs. 14. Johan. Schenck. Obs. Med. lib. v. obs. 2.

The mode in which pediculi are generated being now well ascertained, and such fatal swarms of them being altogether unknown in modern experience, we can scarcely give credit to these accounts. They are not only in all probability much exaggerated, but have actually originated in mistake. We have shewn in a former article (see INSECTS infesting the human body), that the larvæ or grubs of several winged insects, especially those of the common fly (*Musca domestica*, Linn.), and of the black beetle (*Tenebrio molitor*), not unfrequently breed, both in the internal passages, and in external wounds, of the human body. And in warm climates, the flies are so numerous about the persons of the sick, that the utmost care is requisite to prevent the generation of larvæ from the eggs which they deposit, not only in superficial wounds, but in the nostrils, mouth, gums, &c. sometimes even penetrating to the brain itself, and producing death. (See Dr. Lempiere's Observat. on the Diseases of the Army in Jamaica, vol. ii. p. 182.) In the same way maggots are sometimes generated in the patches of cutaneous eruptions, as described by professor Murray of Gottingen in the case of leprosy. (See his Obs. de Vermibus in Lepra obviis. p. 25.—See also Bateman's Pract. Synopsis of Cutaneous Diseases, p. 21. and Edin. Medical and Surg. Journal, for January 1811, p. 41.) From this view of the subject, therefore, little doubt can remain, that the fatal cases of antiquity, above alluded to, occurring in the warmer regions of Europe, were in reality cases of ulceration, arising from scurvy or some other cachectic condition, which afforded a nidus for the breeding of the maggots of flies, and were not true instances of the morbus pedicularis.

The generation of lice, however, in connection with the prurigo of elderly people, though not fatal, is frequently a very troublesome and obstinate malady, and many external applications have been resorted to from ancient times to destroy these loathsome and irritating parasites. But the destruction of them is commonly a mere alleviation; since their reproduction is extremely rapid. A decoction of the seeds of stavacre, or of the cocculus indicus, or the powder of either of these substances, alone or mixed with lard in the form of an ointment, are very effectual destroyers of the pediculi of the head, and even of the body-lice. The mercurial ointments, such as that of the white precipitated oxyd, are also very efficacious in the same instances. For the *morpiones*, or crab-lice, as they are called from their round and flattened form, which fix themselves firmly in the skin, about the pubes, axillæ, and in fact on every part of the trunk and extremities where there is hair, are instantly and completely destroyed by inunction with the common blue mercurial ointment. The spike-oil, as it has

been called, which is the essential oil of lavender, mixed with oil of turpentine, has been deemed the most efficacious poison for these *morpiones*: its virtue depends perhaps principally upon the oil of turpentine, which is doubtless the most ready instrument of destruction to all the insect tribe. Sir Edward Wilmot is said by Dr. Heberden to have used, with complete success, in a case of morbus pedicularis, a composition somewhat similar to the spike-oil; viz. of rectified oil of turpentine, and spirit of wine, each four ounces, camphor six drachms. A solution of the corrosive muriate of mercury in spirit is also often efficacious in the pedicular prurigo of the body, and tends to remove the pruriginous affection of the skin, which seems to give rise to the tendency to generate lice. It is to be observed, however, as a matter of caution, that none of these pungent stimulating substances can be applied to the skin, without inflicting extreme pain, unless its surface be unbroken: for where the cuticle is abraded by scratching, or by the breaking of pustules and vesicles, or by the formation of rhagades or chaps, the irritation and smarting excited by them is intolerable, and is followed by considerable inflammation.

PTHIRION, in *Botany*, a name used by some authors for the *pedicularis*, or red rattle.

PTHIROPHAGI, in *Ancient Geography*, the name of a people who inhabited the coasts of the Euxine sea. Mela.

PTHISIS, in *Medicine*, from *θηω*, to corrupt, signifying corruption or emaciation in general, is commonly limited to that species of emaciation, which arises from a disease of the lungs; whence the epithet *pulmonalis* is usually conjoined with it, denoting *pulmonary consumption*. See CONSUMPTION.

PTHUTH, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana. Ptolemy.

PHU, in *Botany*, a name by which some authors call the great garden valerian.

PHUCAGROSTIS, *φυκαγροστις*, from *φυκος*, a sea-weed, and *αγροστις*, grass, a name which has been applied to the *Zosteræ*, or Grass-wrack. Cavolini, an eminent Neapolitan naturalist, has given it a temporary adoption, to distinguish one of the genera, of which he has found several confounded under *Zosteræ*. His *Phucagrostis* is, however, well shewn by Mr. König, in Ann. of Bot. v. 2. 92, to be itself the true Linnæan *Zosteræ*; and the name is, moreover, inadmissible, as being compounded of two already established, *Agrostis* and *Fucus*; in which respect it is no less faulty than the *Calamagrostis* of some writers.

PHUMANA, in *Ancient Geography*, a town of Asia, in Babylonia, in the vicinity of Arabia deserta, according to Ptolemy, who marks it between Chuduca and Coesa.

PHUPHAGENA, a town of Asia, in Lesser Armenia, in the interior of the country towards the mountains between Arana and Mardara, according to Ptolemy.

PHUPHENA, a town of Asia, in the interior and near the mountains of the Lesser Armenia, between Ispa and Arana, according to Ptolemy.

PHUSIANA, a town of Asia, in the interior of Assyria, between Gomara and Hone, according to Ptolemy.

PHUSIPARA, a town of Asia, in Lesser Armenia, between Cienica and Eufimara. Ptolemy.

PHUT, a country and river of Africa, in Mauritania Tingitana. Pliny.

PHYCIS, in *Ichthyology*, the name of a species of blennius, called *linca marina*, or sea-tench: the lesser hake of the British zoology.

PHYCIS is also a name given by Artedi, after Aristotle, Pliny, and the rest of the ancients, to a fish nearly allied

to the genus of the *blenni*, and called by some *trebius* and *fuca*; and, according to Rondeletius, the *tinca marina* of the Italians. Salvia, however, denies that it is the *tinca marina*, and the matter is yet undecided among the writers on this subject.

PHYCITES, in *Natural History*, the name given by the ancients to a stone which had the impression of a sea-plant of the fucus or alga kind; probably in the manner in which our black coal slate is frequently found to contain the impressions of fern and other vegetables.

PHYCTEUM, in *Ancient Geography*, a town of Greece, in the Peloponnesus.

PHYCUS, a promontory and fortress of Africa, in Cyrenaica, between Aptuchi Fanum and Apollonia. Ptolemy.

PHYCUSSÆ, islands of Libya. Steph. Byz.

PHYGELA, a town of Asia Minor, in Ionia. Mela and Pliny.

PHYGETHLON, in *Surgery*, a carbuncle, or a phlegmon attended with considerable heat, pain, redness, &c.

PHYLA, in *Botany*, a genus of Loureiro's, named by him from *φυλα*, a tribe, or company, because a considerable number of flowers are produced from one common calyx. Loureir. Cochinch. 66.—Class and order, *Tetrandria Monogynia*.

Gen. Ch. *Common Calyx* ovate, imbricated, of numerous, crowded, spatulate, pointed leaves, containing many flowers. Perianth inferior, of two lanceolate, concave, erect leaves. *Cor.* of one petal, tubular, irregular; limb short, spreading, in four nearly equal segments, the uppermost emarginate. *Stam.* Filaments four, short, in two rows below the mouth of the tube; anthers roundish, two-lobed. *Pist.* Germen superior, roundish; style short; stigma thickish. *Peric.* none. *Seeds* solitary, naked, covering a thread-shaped, naked, common receptacle.

Ess. Ch. *Common calyx* imbricated; proper of two leaves, inferior. *Corolla* four-cleft, irregular. *Anthers* roundish, within the tube. *Seed* solitary.

1. *Ph. chinensis*.—Native of China, where it is called *Lien süen*. The stem is herbaceous, annual, creeping, with ascending branches. *Leaves* opposite, ovato-lanceolate, pointed, smooth, serrated towards the point only. *Flower* pale violet, lateral, on a long solitary stalk. The author suspected an affinity between this plant and *Protea*, guided, as it seems, by the artificial characters only, by which many an honest man, setting a false step in the beginning, has, like Gulliver's Laputian mathematicians, been led widely astray. Nothing indeed can less accord with *Protea*, than the plant indicated by the above description, which we strongly suspect to be no other than *Verbena nodiflora*! In that case however the seeds should have been described two to each flower.

PHYLACA, in *Ancient Geography*, a place in the Peloponnesus, where is the source of the river Alpheus. Pausanias.—Also, a town of Epirus, in the Molosside. Livy.—Also, a town of Macedonia, in Pieria. Ptolemy.

PHYLACISTÆ, among the *Ancients*, officers to whose keeping the slaves in prisons and work-houses were committed.

PHYLACTERY, *φυλακτήριον*, signifying a memorial or preservative, in *Ecclesiastical History*, a slip of parchment, wherein was written some text of holy scripture, particularly of the Decalogue; which the more devout people among the Jews inclosed in leather cases, and bound with thongs on the forehead, and on the left arm. (See **FRONTAL**.) On these phylacteries were written thirty passages out of Exodus and Deuteronomy. The phylacteries for

the head had four cavities, into each of which was put one of the four following sections of the laws, viz. Exod. xiii. 1—10. Exod. xiii. 11—16. Deut. vi. 4—9. Deut. xi. 12—13. The other has but one cavity, and into that four sections are put.

They derived their name from *φυλακτω*, *I keep*, either because they were supposed to preserve the law in memory, or rather, because they were looked upon as a kind of amulets or charms to keep them from danger. They were called *הפליין*, *tephillin*, by the Jews. The Pharisees, in order to maintain an appearance of greater sanctity, or to attract notice by their ostentation, wore broader phylacteries, and larger fringes to their garments than the rest of the Jews. (Matt. xxiii. 5.) Some authors have inferred from Exod. xiii. 9. and Deut. vi. 8. that these phylacteries were of divine institution. But these passages may be taken in a figurative sense, as they are by the Caraites, who wear no phylacteries at all. In our Saviour's time, however, they were worn by the Jews in general, by the Sadducees, who received only the law, as well as by the Pharisees, but with this difference, that those of the latter were larger than the others.

PHYLACTERY, in the general, was the name given by the ancients to all kinds of charms, spells, or characters, which they wore about them, as amulets, to preserve them from dangers or diseases.

The primitive Christians also gave the name phylacteries to the cases wherein they inclosed the relics of their dead.

PHYLARCHUS, *φυλαρχος*, among the Athenians. The phylarchi were magistrates, who had each of them the government of a tribe committed to his charge; and their business was to take care of the public treasures belonging to each tribe, to manage all their concerns, and call them together as oft as any thing happened that required the presence of the whole body.

PHYLATERIA, a name given by some botanical authors to the *polium*, or poly-mountain.

PHYLICA, in *Botany*, an ancient Greek name, occasionally written either *φυλικη* or *φυλικη*; but to what it properly belongs, commentators have not determined. Theodore Gaza supposed it our Holly, *Ilex Aquifolium*. It is acknowledged to have been a tree or shrub with evergreen leaves, and possibly the name may have originated from *φυλλικός*, *leafy*; in which sense it is well applied to the present Linnæan genus, consisting of shrubs with very copious evergreen foliage.—Linn. Gen. 105. Schreb. 142. Willd. Sp. Pl. v. 1. 1108. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 19. Thunb. Prodr. 44. Juss. 381. Lamarck Illustr. t. 127. Gært. t. 24.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumosa*, Linn. *Rhamnii*, Juss.

Gen. Ch. *Cal.* Common receptacle of the fructification scaly, collecting the flowers into a disk. *Perianth* superior, of one leaf, in five deep segments, turbinate, villous internally, permanent. *Cor.* none, except five minute, pointed, vaulted, converging scales, one at the base of each segment of the calyx. *Stam.* Filaments five, minute, under the five scales; anthers simple. *Pist.* Germen inferior, roundish; style simple; stigma obtuse. *Peric.* Capsule roundish, three-lobed, with three cells and three valves. *Seeds* solitary, roundish, gibbous at one side, angular at the other.

Ess. Ch. *Perianth* in five deep segments, turbinate. Scales five, covering the stamens. Capsule inferior, of three cells. *Seeds* solitary.

All the known species of *Phylica* are natives of southern Africa, chiefly about the Cape of Good Hope. Linnaeus defines six only in *Sp. Pl.* ed. 2, but the 14th ed. of *Syll. Veg.*

Fig., contains twelve. Willdenow has nineteen; Thunberg's *Prodromus* seventeen. The new edition of the *Hortus Kewensis* mentions twelve as cultivated in the gardens about London, most of them introduced by the late Mr. Masson. They are greenhouse shrubs, flowering for the most part in the winter or early spring, distinguished by a bushy heath-like habit; copious, minute, terminal, white or woolly *bloffoms*; and small, simple, numerous, scattered, linear or ovate *leaves*, whose upper surface is of a dark or shining green, the under pale, hoary, or woolly. Their *footstalks* are short, and in one instance at least accompanied by a pair of awl-shaped *stipulas*. As the species require no critical illustration, the following will be sufficient examples.

Ph. ericoides. Heath-leaved Phylica. Linn. Sp. Pl. 283. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 224. (*Alaternoides africana*, *ericæ foliis*, *floribus albicantibus et mucosis*; *Comm. Hort. v. 2. 1. t. 1.*)—Leaves linear, revolute, imperfectly whorled. Flowers woolly.—Miller, and Curtis after him, erroneously assert this species to be a native of Portugal, covering extensive tracts of ground about Lisbon, as heath does in England. It is not mentioned by Brotero, in his *Flora Lusitanica*, nor does any other writer speak of it but as a Cape plant, brought into England above seventy years ago, and still common in every greenhouse. The *stem* is very much and determinately branched. *Leaves* rather above half an inch long, crowded, spreading in every direction, bright green, somewhat hairy, linear-lanceolate, revolute, with a narrow hairy furrow beneath. *Flowers* in small terminal heads, conspicuous for the snow-white tufted woolliness which crowns their *calyx*, like what is seen on the *corolla* of a *LEUCOPOGON*; see that article.

Ph. bicolor. White and yellow Phylica. Linn. Mant. 208. Willd. n. 3. (*Ph. strigosa*; Thunb. Prodr. 44?)—Leaves linear, revolute, hairy, scattered; woolly beneath. Flowers hairy, longer than the floral leaves.—Found in sandy ground at the Cape, but a stranger to our gardens. Twice as large in every part as the former, with which its habit and *foliage* otherwise nearly agree; but the pubescence of the *calyx* consists in long straight silky hairs, not opaque white woolliness, and the *flowers* are accompanied by numerous crowded floral leaves, densely clothed with similar, but tawny, hairs. We have seen no specimen of Thunberg's *strigosa*, and therefore follow Willdenow in citing him with a mark of doubt, though his specific character leaves scarcely any room for hesitation:

Ph. stipularis. Horned Phylica. Linn. Mant. 208. Willd. n. 9. Ait. n. 7. (*Chamælea foliis angustis subtus incanis*, *floribus capitatis mucosis*; *Burm. Afr. 117. t. 43. f. 2.*)—Leaves linear, revolute. *Stipulas* acute. Segments of the calyx elongated, awl-shaped, externally woolly.—Introduced by Mr. Masson in 1786, but has not yet blossomed. This is distinguished by a pair of minute, awl-shaped, acute, brownish *stipulas*, situated rather within the insertion of the *footstalk*, as in the genus *Pultenæa*; and by the remarkably long woolly points of the *calyx*, which had induced Linnæus, at one period, to call the species *cornuta*.

Ph. pinifolia. Pine-leaved Phylica. Linn. Suppl. 153. Willd. n. 10. Ait. n. 8.—Leaves linear, flat on both sides, very smooth. Spikes paniced. Flowers smooth; each about as long as its solitary ovate bractea.—Native of lofty mountains. Remarkable for its great smoothness, and flat fir-like *leaves*. The smoothness and form of the minute *flowers* are such, that Burmann mistook it for a species of *Backea*, nor is its habit dissimilar from that otherwise very remote genus.

Ph. buxifolia. Box-leaved Phylica. Linn. Sp. Pl. 283.

Willd. n. 13. Ait. n. 10. (*Chamælea foliis subrotundo subtus incano*, *floribus in capitulum collectis*; *Burm. Afric. 119. t. 44. f. 1.*)—Leaves ovate, scattered or ternate; downy beneath.—Common in collections, flowering most part of the year. The *leaves* are rather elliptical, pointed, almost an inch long, and half an inch wide; rough with points, and of a dark shining green, above; covered beneath with dense white wool. *Flowers* numerous, in little round terminal white heads.

Ph. racemosa. Racemose Smooth Phylica. Linn. Mant. 209. Willd. n. 18.—Leaves ovate, dotted, smooth, or slightly fringed. Spikes paniced. Flowers smooth; each about as long as its solitary heart-shaped bractea.—Found about ditches at the Cape, but not yet brought to England. The *flowers* and *inflorescence* nearly resemble *pinifolia*, inasmuch that this species was likewise made a *Backea* by Burmann in his *Prodromus*. The short, broad ovate *leaves*, rough with minute dots, and often fringed with hairs, abundantly distinguish it from *pinifolia* and every other. The *branches* are hairy.

PHYLICA, in *Gardening*, contains plants of the shrubby, evergreen, exotic kind,—bastard alaternus,—of which the species cultivated are; the heath-leaved phylica (*P. ericoides*); the woolly-leaved phylica (*P. plumosa*); and the box-leaved phylica (*P. buxifolia*).

Method of Culture.—They are chiefly increased by cuttings and slips of the young shoots. In spring, as about March or April, a quantity of young cuttings, or slips of the small shoots, should be taken off, planting them in pots of rich earth, plunging them in a hot-bed, or in the bark-bed in the stove; giving frequent waterings, and occasional shade from the sun, when they will soon emit roots, and become proper plants fit for potting off separately in autumn: or the young cuttings or slips may be planted any time in summer, particularly in June and July, in pots as above, and placed under a hot-bed frame, or covered close with hand-glasses, being watered and shaded; when they will also grow, but not to be so forward as those of the spring planting.

These are somewhat tender plants, requiring shelter in winter in this climate: of course they must always be kept in pots, and placed among the greenhouse exotics, where they will effect a very agreeable variety at all seasons, and flower annually a great part of the autumn and winter, but do not produce seed in this climate.

PHYLITÆ, in *Ancient Geography*, a people of India, on this side of the Ganges; placed by Ptolemy with the Bittigi, near the river Nanaguna.

PHYLLACHNE, in *Botany*, received that appellation from Forster, in allusion to the slender chaffy aspect of its foliage and calyx, the word being derived from *φυλλον*, a leaf, and *αχνη*, a husk. *Forst. Gen. t. 58. Linn. Suppl. 62. Schreb. 672. Mart. Mill. Dict. v. 3. Swartz in Sims and König's Ann. of Bot. v. 1. 286. t. 5. Juss. 422. Lamarck Illustr. t. 741. — Class and order, Gynandria Diandria. Nat. Ord. akin, at least, to the Campanaceæ of Linn. and Juss. See FORSTERA, with which genus Swartz has united the above-mentioned.*

PHYLLAMPHORA, from *αμφορες*, a wine jar, and *φυλλον*, a leaf, a name given by Loureiro, in his *Cochinch. 606*, to the Linnæan NEPENTHES, see that article, in allusion to the pitcher-like appendage to the leaf. The author had a suspicion that his plant might be that of Linnæus, but he could not make it tally with the description. There is, however, no doubt of their identity.

PHYLLANTHUS, from *φυλλον*, a leaf, and *ανθος*, a flower, because the flowers, in one of the original species, grow

grow out of the leaves; but that species is now a *Xylophylla*. Pliny has a *Phyllanthus*, of which we know enough only to prove that it is different from our's. Linn. Gen. 484. Schreb. 628. Willd. Sp. Pl. v. 4. 573. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 333. Juffl. 386. Lamarck Illustr. t. 756. Gærtner. t. 108. Clafs and order, *Monoecia Monadelphica*. Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juffl.

Gen. Ch. Male, *Cal.* Perianth of one leaf, bell-shaped, coloured, in fix deep, ovate, obtufe, spreading, permanent segments. *Cor.* none, except the calyx be taken for fuch. *Stam.* Filaments united into a column; anthers three, two-lobed.

Female, on the fame plant, and in the fame fiteuation, as the male, *Cal.* Perianth as in the male. *Cor.* Petals none. Nectary a border with 12 angles, furrounding the germen. *Pist.* Germen fuperior, roundifh, with three blunt angles; ftyles three, spreading, cloven; ftigmas obtufe. *Peric.* Capfule roundifh, with three furrows, three cells, and fix elastic valves. *Seeds* folitary, roundifh.

Eff. Ch. Male, Calyx in fix deep segments. Corolla none. Filament columnar. Anthers three.

Female, Calyx in fix deep segments. Petals none. Nectary a border with twelve angles. Styles three. Capfule three-lobed, with fix elastic valves.

Obf. Willdenow describes *Ph. obovatus* with fix anthers.

Much uncertainty has exifted, and does ftill exift, refpefting the plants that ftictly belong to this genus. Linnæus has but fix fpecies in the 2d edition of Sp. Pl. and feven in the 14th ed. of Syft. Veg. He always confidered *Phyllanthus* as having three feperate ftamens, but this is certainly a miftake, at leaft as far as we have been able to examine. Willdenow has augmented the genus to 36 fpecies, and he wifhes to unite with it the whole of *Xylophylla*, Willd. Sp. Pl. v. 1. 1500, making feven fpecies more. We conceive the latter propofal to be inadmittible, and thefe genera are kept diftinct in the recent edition of Hort. Kew. though placed next to each other in the *Monoecia Monadelphica*. This laft point will be confidered hereafter, when we come to XYLOPHYLLA. Nine fpecies of *Phyllanthus* are enumerated as cultivated in the Britifh collections, where they are moftly ftove fhrebs, chiefly remarkable for their delicate pinnate foliage, refembling fome *Mimosa*, and turning red in decay. Many of them, however, have fimple leaves. The flowers are fmall, greenifh, axillary, copious, on fhort flender ftalks. Very few of the fpecies are figured in any botanical works, and none in our periodical ones. We fhall enumerate a few fpecies.

Ph. obovatus. Annual Carolina Phyllanthus. Willd. n. 3. Ait. n. 1. (*Ph. carolinensis*; Michaux Boreal-Amer. v. 2. 209.)—Leaves fimple, obovate, bluntifh. Flowers axillary, ftalked, in pairs. Stem branched, round, erect. Native of North America. It was introduced in 1803 by Robert Barclay, efq. to whom the gardens are indebted for feveral of the more curious, though lefs oftentatious, American plants, overlooked by vulgar collectors and admirers. The prefent is a hardy annual, flowering in July and Auguft. *Stem* much branched. *Leaves* ftalked, alternate, not an inch long, entire, fmoth; bright green above; paler beneath. *Stipulas* fmall, membranous. *Flowers* fmall, greenifh, one male, the other female. *Capfule* fcarcely fo big as hemp-feed.

Ph. bacciformis. Berry-shaped Phyllanthus. Linn. Suppl. 415. Willd. n. 25. Konig in Ann. of Bot. v. 1. 357. (*Agyneia impubes*; Venten. Jard. de Cels. t. 23; but not of Linnæus.)—Leaves two-ranked, elliptical. Branches two-edged. Flowers axillary; the upper ones fe-

male, folitary; the lower male, three together.—Native of Tranquebar. *Root* annual. *Stems* numerous, fpreading widely, befet with numerous leafy branches. *Leaves* broadly elliptical, hardly an inch long. *Stipulas* awl-shaped. *Flowers* green. Mr. Konig has fhewn the miftake of M. Ventenat, in fupposing this the true *Agyneia impubes* of Linnæus, who is thereby vindicated from the abundance of errors in the defcription, with which the learned, not uncandid, Frenchman rather too haftily charges him. The *Agyneia* in queftion is figured in the above Ann. of Bot. t. 7. f. 4.

Ph. Emblica. Shrubby Eaft Indian Phyllanthus. Linn. Sp. Pl. 1393. Willd. n. 36. Ait. n. 9. (*Myrobalanus Emblica*; Rumph. Amboyn. v. 7. 1. t. 1. Nilicamaram; Rheede Hort. Malab. v. 1. 69. t. 38.)—Leaves pinnate, bearing the flowers; leaflets oblong, rather acute; foot-ftalks round, downy. Flowers aggregate. Stem fhubby. Native of the Eaft Indies; long cultivated in our ftoves. No time for its bloffoming is marked in the Hort. Kew. but we had a flowering fpecimen from Mr. Salifbury's collection in 1788. The leaves are elegantly tinged with red. We can hardly believe them to be really pinnate and floriferous, but fhould rather confider as branches, what are termed their common foot-ftalks, and from the lower part of which copious axillary tufts of little yellowifh flowers come forth. The fruit is as large as an ordinary goofeberry, and is figured under the name of *Emblica*, in Gærtner t. 108. It does not appear to be more pulpy than that of other fpecies.

PHYLLANTHUS, in Gardening, furnifhes plants of the evergreen exotic tree and fhubby kind: the fea-fide laurel, of which the fpecies cultivated are, the annual phyllanthus (*P. niruri*); the great-leaved phyllanthus (*P. grandifolia*); and the fhubby phyllanthus (*P. emblica*).

Method of Culture.—Thefe plants, where feeds can be procured from their native fiteuations, may be raifed in that way. They fhould be fown in pots filled with light earth, and plunged in a hot-bed; and when the plants have acquired fome growth, they fhould be planted out into feperate pots filled with the fame fort of mould; being replunged in the hot-bed, due fhade and water being given, until they become perfectly rooted; after which they fhould be constantly kept in the bark-bed of the ftove, and have the management of other plants of the fame tender fort.

They may alfo fometimes be raifed by planting out flips, or by layers managed in the fame way as thofe from feeds.

They afford a fine variety in their beautiful foliage, and the flowery kinds have a fingular effect in their flowers.

PHYLLAUREA, in Botany, a hybrid Greek and Latin name, from *φυλλον*, a leaf, and *aureus*, golden, given by Loureiro to the *Croton variegatum* of other authors, of which he makes a diftinct genus; Lour. Cochinch. 575. We greatly doubt the propriety of the meafure, and the name is certainly inadmittible.

PHYLLEIUS, in Ancient Geography, the name of a country, a mountain, and a town of Macedonia.

PHYLLIREA, in Botany. See PHILLYREA.

PHYLLIS is, by Linnæus, in his Philofophia Botanica, reckoned among the poetic names, familiar in ancient ftory, like *Hyacinthus*, *Narciffus*, &c. But in his Hortus Cliffortianus, he mentions having particularly chofen this appellation for the plant which now bears it, becaufe the beauty of the fhreb chiefly confifts in its leaves. *Phyllis* would have been more peculiarly appofite for any fhreb or tree producing an exuberant foliage fuddenly from naked branches, like the Almond, into which the unfortunate Thracian queen was fupposed to be metamorphofed.

Linn. Gen. 126. Schreb. 177. Willd. Sp. Pl. v. 1. 1354. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 114. Juss. 198. Lamarck Illustr. t. 186. Gærtn. t. 25. Clafs and order, *Pentandria Digynia*. Nat. Ord. *Stellate*, Linn. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, obsolete, of two minute leaves. *Cor.* Petals five, lanceolate, obtuse, revolute, scarcely connected at the base. *Stam.* Filaments five, shorter than the corolla, capillary, flaccid; anthers simple, oblong. *Pist.* Germen inferior, obovate; style none; stigmas two, awl-shaped, downy, reflexed. *Peric.* none. Fruit oblong, somewhat turbinate, obtuse, angular. *Seeds* two, parallel, convex and angular at the outer side, flat at the inner, broader upwards.

Eff. Ch. Stigmas rough. Calyx of two leaves. Petals five. Seeds two.

Obf. Linnæus remarks that the stigmas resemble those of the grasses, the elm, and *Tetragonia*. He seems originally to have had, like Boerhaave, who called this plant *Bupleuroides*, an idea of its affinity to the umbelliferous order; but he has justly referred it subsequently to his *Stellate*; so that what regards the inflorescence in his *Genera Plantarum* is entirely misplaced.

1. *Ph. Nobla*. Bastard Hare's-ear. Linn. Sp. Pl. 335. (*Valerianella canariensis frutescens*, Simpla nobla dicta; Dill. Elth. 405. t. 299. *Bupleuroides*; Walth. Hort. 11. t. 6.)—Native of the Canary islands, where it is called *Simpla nobla*. It has been known for above a century in our gardens, where it is kept in the greenhouse, and flowers in June and July, but is valued rather for variety than beauty. The stem is shrubby, two or three feet high, with round smooth leafy branches; the lower part of a light corky aspect. Leaves opposite, on stalks, elliptic-lanceolate, acute, entire, smooth, two or three inches long. *Stipulas* between the footstalks, oblong, erect, strongly toothed and glandular, especially the upper ones. *Panicle* terminal, leafy, oblong, smooth, of numerous small green flowers. *Fruit* the size of a grape-stone.

This is the only known species of its genus, *Ph. indica*, Sp. Pl. 336, being struck out by Linnæus in his *Mantissa altera*, 349.

PHYLIS, in *Gardening*, contains plants of the shrubby, evergreen, exotic kind, of which the species cultivated is the bastard-hare's-ear (*P. nobla*).

Method of Culture.—The plants may be increased by sowing the seeds in the early spring months, as about March, in pots filled with light earth, and plunged in a hot-bed; and when the plants have attained some growth, they should be planted out in separate pots, replunging them in the hot-bed, due shade being given till they become well rooted. In the summer season they should be set out in a sheltered situation, so as to have the morning sun, and be frequently watered. In the winter they must be well sheltered from frost, but have as much air as possible in mild weather.

In the second year, when the plants are shaken out of the pots and placed in a proper situation in the open ground, they flower better, and afford more perfect seeds, than when kept in pots.

They may also be raised by cuttings planted out in the summer season.

New plants should be raised every two or three years, as they do not last long.

They afford an agreeable variety among other evergreen plants of the greenhouse kind.

PHYLLITIS MARINA, in *Natural History*. See *HART'S tongue*.

PHYLLOBOLIA, *φύλλοβωλία*, in *Antiquity*, a custom

that prevailed among the ancients to strew flowers and leaves on the tombs of the dead. The Romans adopted this custom from the Greeks, and added likewise wool. See **BURIAL**.

The *phyllobolia* was also used on occasion of a victory obtained at any of the public games; when not only the victors, but likewise their parents, were strewed with flowers and leaves.

PHYLLODES, in *Botany*. See **PHRYNIUM**.

PHYLLOMA, so named by Mr. Ker in Curtis's Magazine, from *φυλλον*, a leaf, and *λωμα*, a fringe or border, alluding to the coloured toothed margin of the leaves. Ker in Curt. Mag. v. 38. 1585. Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Coronarieæ*, Linn. *Aphodeli*, Juss.

Gen. Ch. *Cal.* none. *Cor.* Petals six, oblong, nearly erect, equal, cohering by their claws; three of them internal. *Stam.* Filaments six, inserted into the receptacle, thread-shaped, erect, equal, rather shorter than the corolla; anthers oblong, incumbent. *Pist.* Germen superior, roundish, three-lobed; style awl-shaped; stigma simple. *Peric.* Berry tough, spherical, depressed, with three furrows, and three cells. *Seeds* numerous in each cell, in two rows, horizontal, oblong, angular, polished.

Eff. Ch. Corolla of six petals, erect. Filaments thread-shaped. Berry of three cells. Seeds numerous, angular.

1. *Ph. marginatum*. Aloe-leaved Phylloma. (*Ph. aloiflorum*; Curt. Mag. t. 1585. *Dracæna marginata*; Ait. Hort. Kew. ed. 1. v. 1. 454. ed. 2. v. 2. 277. Willd. Sp. Pl. v. 2. 157.)—The only known species, said to be a native of the island of Bourbon. M. Richard is mentioned as having sent it to Kew in 1766. There is a fine specimen of this plant in the stove at Chelsea, which flowers in the spring, and often ripens fruit. The stem is shrubby, several feet high, and probably forming, in its native country, a small and thick tree, with all the appearance of an arborescent *Aloe*. Leaves a yard long, succulent, smooth, taper-pointed, green, with a dull red, strongly toothed, or jagged, edge. *Common flower-stalk* axillary, compressed, similarly coloured, but not toothed, at the edges; *partial* ones alternate, round, spreading, red. *Flowers* numerous, racemose, each scarcely an inch long, of a tawny yellow. *Bractææ* solitary, taper-pointed, red. *Fruit* purplish-black, nearly the size and shape of a bullace plum.

The even filaments, and numerous seeds, well distinguish this, as a genus, from *Dracæna*. Its habit is like *Aloe*, but their characters are sufficiently different. We retain the excellent original specific name, as far preferable to *aloiflorum*, and certainly requiring no alteration.

PHYLLOS, in *Ancient Geography*, a country of the Peloponnesus, in Arcadia, according to Statius in his *Thebaid*.

PHYLLUS, a town of Thessaly, in which Strabo has placed a temple of the Phyllæan Jupiter.

PHYLOBASILES, *φυλοβασίλει*; among the Athenians, magistrates, who, with respect to particular tribes, had the same office that the *basilæus* had with respect to the commonwealth.

They were chosen out of the eupatridæ or nobility, had the care of public sacrifices, and other divine worship peculiar to their respective tribes, and kept their court in the portico called *basilæion*, and sometimes in the *bucolæian*.

PHYMA, *φυμα*, from *φύμαι*, to grow, as plants from the earth, a term used by the ancients to denote almost every species of external and superficial tumour, arising without any obvious external injury. It comprehends, therefore, boils, glandular enlargements, cutaneous tubercles, and even large inflamed pustules, or small abscesses. See *Galen*;

in Comment. ad bib. vi. Epidem. Celsus, de Med. lib. ii. cap. 7.

PHYMA, in *Surgery*, any superficial inflammatory swelling, which quickly falls into a state of suppuration.

PHYMOSIS. See PHIMOSIS.

PHYRAMA, in the *Materia Medica*, a name given by some of the old writers to the gum ammoniacum, particularly to that part of it which was soft and ductile between the fingers. It is not clear that the gum ammoniacum of those times was the same thing which we now know by that name; at least it is certain, that the other kind of it, which they called *thrauma*, or *ammoniacum thraulsum*, was not; for Dioscorides describes this as being of a reddish-brown colour, and very friable; and Avicenna says, that it marked a fine yellow or gold colour upon paper. These are properties by no means agreeing with our gum ammoniacum; and if justly applicable to that, must prove that it could not be the same; and the characters given by Avicenna of its bitterness, and making a yellow stain upon paper, seem to make it the gamboge. This, however, by no means can agree with the other virtues attributed to it.

PHYSALIS, in *Botany*, *φυσάλις*; of the Greeks, from *φύσις*, a bladder, an old name, applied by Linnæus to the *Alkekengi* of some preceding writers, the bladderly inflated calyx of which it well announces.—Linn. Gen. 99. Schreb. 134. Willd. Sp. Pl. v. 1. 1019. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 392. Brown Prodr. Nov. Holl. v. 1. 447. Juss. 126. Lamarck Illustr. t. 116. Gærtn. t. 131. (*Alkekengi*; Tourn. t. 64.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solanææ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, swelling, small, five-sided, cut half way down into five pointed segments, permanent. *Cor.* of one petal, wheel-shaped; tube very short; limb large, plaited, cut half way down into five broad acute segments. *Stam.* Filaments five, awl-shaped, very small, converging; anthers erect, approaching each other. *Pist.* Germen superior, roundish; style thread-shaped, rather longer than the stamens; stigma obtuse. *Peric.* Berry nearly globose, of two cells, small, within the enlarged, inflated, closed, five-sided, coloured calyx. *Receptacle* kidney-shaped, double. *Seeds* numerous, kidney-shaped, compressed.

Eff. Ch. Corolla wheel-shaped, plaited. Anthers converging, bursting lengthwise. Berry of two cells, within the inflated, angular, membranous calyx.

A genus of lurid, chiefly downy, viscid and fetid plants, almost entirely extra-european, whose fruit in several instances is eatable, though principally valuable only for an acidity, grateful in hot climates. The species are by no means clearly ascertained, as many of them nearly resemble each other, and few are cultivated except for curiosity; their vulgar dunghill aspect, and rank growth, being hardly compensated by the slight beauty of their flowers, or the singularity of the bladderly calyx. Linnæus has ten species in his Sp. Pl.; thirteen in Syst. Veg. ed. 14. Willdenow reckons up seventeen, fourteen of which are mentioned in Hort. Kew. Mr. Brown has added one, from New Holland. Ten are perennial, and six of those are shrubby; seven are annual, and very much branched.

In the first section are

Ph. somnifera. Clustered Winter-cherry. Linn. Sp. Pl. 261. Willd. n. 1. Ait. n. 1. Cavan. Ic. v. 2. 2. t. 103. (*Solanum somniferum*; Matth. Valgr. v. 2. 417. Ger. Em. 339.)—Stem shrubby. Branches straight. Flowers crowded—Native of Mexico; naturalized, apparently, in Spain. It requires the protection of a green-

house in England, where it has been cultivated from the time of Gerarde to the present day, flowering in July and August. The whole plant is downy, of a pale dull green. *Leaves* ovate, entire, about an inch or two long, scattered, on shortish stalks. *Flowers* small, pale and inconspicuous, crowded among the leaves along the branches. *Fruit* scarlet, the size of a black currant, concealed by the greenish downy calyx. The bark of the root is said to be a safe opiate, milder than opium.

The *Atropa frutescens* of Linnæus is so like this plant in habit, that he justly observes they can hardly belong to different genera; and Cavanilles has, we think not improperly, referred that *Atropa*, though ignorant of its being already described, to *Physalis*, by the name of *suberosa*, in his Ic. t. 102. The calyx, though not closed, is sufficiently inflated in its lower part to excuse this measure.

Ph. viscosa. Clammy Winter-cherry. Linn. Sp. Pl. 261. Willd. n. 7. Ait. n. 6. Jacq. Hort. Vind. v. 2. 64. t. 136. (*Alkekengi bonariense repens, baccâ turbinatâ viscosâ*; Dill. Elth. 11. t. 10.)—Leaves wavy or toothed, obtuse, slightly downy. Stem herbaceous; the upper part cymose. Fruit umbilicated, viscid.—Native of the Brasils; a greenhouse plant in England, but rarely kept, flowering in July. The root is creeping. *Flowers* of a very pale uniform yellow, without spots. *Berry* scarlet, covered with a viscid fluid, and enclosed in a downy calyx.

Ph. Alkekengi. Common Winter-cherry. Linn. Sp. Pl. 262. Willd. n. 9. Ait. n. 8. Sm. Fl. Græc. Sibth. t. 234, unpubl. (*Solanum Halicacabum*; Matth. Valgr. v. 2. 416. Ger. Em. 342.)—Leaves two together, acute, nearly entire. Stem herbaceous, somewhat branched below. Root creeping.—Native of shady rocky places in the south of Europe, very hardy in our gardens, where it spreads widely by means of its perennial creeping roots; flowering in June, but chiefly remarkable for its large, orange-coloured, permanent, drooping calyxes, enclosing fruit of the same colour, and used for decorating many a rustic chimney-piece during winter. The stems are scarcely above 12 or 18 inches high. *Leaves* dark green. *Corolla* white. Dioscorides speaks of the berries as used, with other plants, to twine into garlands; and he records their medical qualities of curing the jaundice, and promoting the urinary secretion. For the latter quality they are celebrated in Lewis's Dispensatory, under the name of *Alkekengi*, though excluded from the more concise Pharmacopœia of the College.

Among the reputed annual species are,

Ph. pubescens. Downy Winter-cherry. Linn. Sp. Pl. 262. Willd. n. 12. Ait. n. 11. Brown Prodr. Nov. Holl. v. 1. 447. Fl. Peruv. v. 2. 41. (*Ph. edulis*; Sims in Curt. Mag. t. 1068. *Alkekengi virginianum, fructu luteo, vulgò Capuli*; Feuill. Peruv. v. 3. 5. t. 1. f. 2.)—Stem angular, much branched. Leaves heart-shaped, somewhat waved, downy. Flowers pendulous. Calyx-teeth sharp.—Native of the warmer parts of America, but now naturalized in the East Indies, at the Cape of Good Hope, and even at Port Jackson, New South Wales, where Mr. Brown informs us it is very plentiful, and known by the name of the Cape Gooseberry, the berries being eaten, either raw, or in various articles of cookery. Dr. Sims speaks of this fruit as agreeably acid and sweet, with a fragrance like a mixture of apple and melon, and he says the plant is perennial and evergreen in a stove, though usually reckoned herbaceous and annual. The flowers are pale yellow, with five large purple spots. The calyx of the fruit is nearly globular, ribbed, tawny. *Berry* yellow. This may be the same with the Linnæan *Ph. peruviana*, but we find nothing positive on that subject.

Ph. parvi-

Ph. parviflora. Small-flowered Winter-cherry. Br. Prodr. Nov. Holl. v. 1. 447.—Stem angular, diffuse. Branches wavy. Leaves ovate, downy, nearly entire. Calyx-teeth acute. Seeds dotted.—Found by Mr. Brown in the tropical part of New Holland. Root annual. Anthers yellow.

Ph. prostrata. Trailing Winter-cherry. L'Herit. Stirp. 43. t. 22. Willd. n. 17. Ait. n. 14. Andr. Repof. t. 75. Jacq. Ic. Rar. t. 38.—Stem procumbent, much branched, round, hairy. Leaves ovate, wavy, somewhat fleshy.—Native of Peru, from whence it was brought by Dombey to the French gardens, and thence introduced amongst us. It is a very tender annual, impatient of cold or wet while young, but in a hot dry summer it bears the open air, and is conspicuous for a profusion of delicate bright blue flowers. The berry is small, dull purple, or brown.

PHYSALIS, in *Gardening*, comprises plants of the herbaceous and shrubby ornamental kind, of which the species cultivated are, the tooth-leaved winter cherry (*P. angulata*); the woolly winter cherry (*P. pubescens*); the common winter cherry (*P. alkekengi*); the Pennsylvanian winter cherry (*P. pensylvanica*); the clammy winter cherry (*P. viscosa*); the clustered winter cherry (*P. somnifera*); the flexuous Italian winter cherry (*P. flexuosa*); the tree-like physalis, or winter cherry (*P. arborescens*); and the Curaffavian winter cherry (*P. curaffavica*).

In the first sort there is a variety which is taller, with entire leaves, smaller flowers of a paler yellow colour.

Method of Culture.—All these plants are capable of being increased by seeds; the second, third, fourth, and fifth sorts, also by parting the roots; the sixth, seventh, eighth, and ninth, likewise by cuttings.

In the first sort, the seed should be sown in the early spring, as April, in pots of light earth, plunging them in a moderate hot-bed. When the plants have acquired a few inches in growth they should be removed into separate pots, gradually inuring them to the open air, in order that they may be removed with balls into the clumps or borders. But it is probably a better method to sow them in the latter end of May in the places where they are to remain, as they do not bear transplanting well. They must be raised annually.

In the herbaceous kinds the seeds should be sown in the autumn as soon as they are ripe, or early in the spring, in the beds, borders, or clumps where they are to remain; or they may be transplanted into other beds to remain till the following autumn, when they may be removed to the situations where they are to remain.

The roots may be parted either in the early autumn or spring season, when the weather is mild. The divided parts should have root-fibres left at the bottoms and a bud in each at the tops in order to their succeeding properly.

In the sixth and seventh sorts, the seed should be sown in pots of light mould in the early spring and plunged in a mild hot-bed. When the plants have had a little growth they should be pricked out into separate small pots, proper shade and water being given; being afterwards managed as the shrubby exotics of less tender plants.

They may likewise be raised from cuttings made in the latter spring or summer months, which should be placed in pots of light mould and plunged in the hot-bed, due shade and water being given till they have stricken root.

And the two last sorts may be raised from seeds or cuttings in the same way, by the aid of the bark hot-bed of the stove.

The first and the other herbaceous sorts are curious ornamental plants in the borders, clumps, and other parts of

pleasure-grounds, and the four best shrubby sorts in the greenhouse and stove collections.

PHYSALUS, a name given by Rondeletius to a species of sea-insect, of the scolopendra marina kind, supposed by some to be the same with the scolopendra marina, or centipes, of the Irish sea, described by Molyneux; but this does not appear to be the case, on a strict enquiry. The physalus of Rondeletius has no mouth, whereas the sea centipes of Ireland has a remarkably large one; that of Rondeletius is wider in the middle, and tapers at each end; but the Irish kind is largest at the head, and tapers from thence all the way to the tail. Rondeletius's has tubercles on the back, but the Irish one has only hairy stripes, and his is a poisonous animal, whereas that of Ireland was found in the stomach of a cod-fish, which had eaten it as food. The figure given by Rondeletius agrees also very well with the account he gives, but not with the figure of that drawn upon the spot from the Irish fish, and given in the Philosophical Transactions. On the whole, nothing is more plain than that these are two distinct species of animals, though of the same genus, Phil. Transf. N^o 225. See SCOLOPENDRA.

PHYSALUS, in *Zoology*, a species of Balæna, with a double opening to the spiracle on the middle of the forepart of the head; and a soft fin on the hinder part of the back; the balæna, having three fins and a smooth belly, of Brisson; the balæna, without teeth, having a narrow body and a fin on the back, of Ray; the physalus bellua, physeter of Gesner; the physeter of Pliny, Willoughby, and others; the fin-fiske of Egede, &c.; the fin-whale of Pennant's Arctic Zoology; the fin-fish of the British Zoology; and the fin-backed whale of Dudley, Phil. Transf. abr. vii. 425. This fish inhabits the Atlantic both on the American and European coasts. It is equal in length to the common whale, but not above a third, or even fourth part of the circumference, and produces much less blubber; the opening of the mouth is larger; the horny lamina, or whale-bone, are shorter, and of a blueish colour. Its flesh is better tasted; and it throws the water from the spiracles with greater force. The upper part of the body of this animal is of a clear brown colour, and the lower parts white; the lips are brown and resemble a twisted rope; on the lower part of the back, near the tail, there is a straight, soft, sharp-pointed fin, between three and four feet long, without rays or bones, from which circumstance the English name of the species, to distinguish it from the common whale, having no back fin, is derived. From the violence with which this species throws out the water from its spiracle, it is supposed to be the *Κυσαλος* of the ancients. This species feeds on small fishes of the clupea, scomber, and other genera. It is neglected by the whale-fishers, on account both of its great fierceness and the small quantity of blubber which it affords: even its appearance in the whale seas is disliked, as it is supposed to drive away the common species, which is so much in request.

PHYSARUM, in *Botany*, a genus of *Fungi* in Perfoon's Syn. 168, whose species are by other writers referred either to *Trichia* or *Reticularia*. Bulliard has described some of them under the name of *Sphaerocarpus*, which properly belongs to one of the *Hepaticæ*, as we propose to shew in its proper place. Perfoon's character of *Physarum* is as follows.

Cafe rigid, simple, mostly somewhat rugged, and rather powdery. Threads internal, scattered, mostly adhering like network to the cafe. He defines 16 species, all small, found either on the trunks of trees, on the ground, or amongst moss.

PHYSICA, or PHYSCÆ, in *Ancient Geography*, a town of the

the Lower Mæsia, between the mouths of the rivers Axia-cus and Tyras. Ptolemy.

PHYSCÆ, a town of Macedonia, in Mygdonia, between Bærus and Terpillus. Ptolemy.

PHYSCELLA, a town of Macedonia, on the gulf Mecybernæus, according to Pliny and P. Mela.

PHYSCIA, in *Botany*, from φυσικη, a bladder, alluding to the concave or inflated receptacles, or shields, of some species; see LICHENES, n. 20.

PHYSCONIA, in *Medicine*, probably from φυσικη, an inflated bladder, a term used by the nosologists to express every species of abdominal tumour, which is hard, not sonorous like tympanites, nor fluctuating like dropsy, nor produced by pregnancy. Under the appellation of Physconia a great variety of morbid enlargement in the abdomen is, therefore, necessarily included; such as scirrhus, fatty, and other tumours of the omentum, morbid growth connected with the ovaria, or uterus, with the intestines or mesentery, with the liver, kidneys, &c. As these tumours are, in fact, extremely different in their nature and origin, the method of treatment appropriate to each can only be determined by an investigation of each variety; but it must be acknowledged, that, as they result from actual organic change in the structure of the parts diseased, little that is effectually curative is within the reach of art. See Sauvages, Nosol. Meth. class x. genus 8.

PHYSCUS, in *Ancient Geography*, a town of Asia Minor, upon the coast of the Doride, over-against the island of Rhodes, according to Diodorus Siculus. Strabo says that it had a port. It was called Physcia by Steph. Byz. and Phusca by Ptolemy.—Also, a port of Asia Minor, in Caria, N.E. of mount Loryma, W. of the promontory Pedalium. In this port there were a town and a river of the same name.—Also, a town of Greece, in the country of the Locri Ozoli. Plutarch.—Also, a port of the island of Rhodes.—Also, a river of Asia, in the vicinity of Assyria.—Also, a mountain of Italy, in Magna Græcia, near Crotona.

PHYSETER, the *Cachalot*, in *Ichthyology*, a genus of animals of the class and order Mammalia Cete, of which the generic character is, teeth in the lower jaw, and none in the upper. The name physeter is of Greek origin, and is derived from the verb φυσω, to blow. It has this name from its quality of taking in a great quantity of sea-water, and then blowing it out again with great force and violence. There are four species in the Linnæan system by Gmelin, which are as follow.

Species.

* CATODON; lesser Cachalot. It has no dorsal fin; but a fistula or spiracle on the snout. It is about 25 feet in length; inhabits the Northern sea, and has been found on the coast of Scotland. The head is round, and the mouth small. In its general structure is very nearly allied to the macrocephalus, to be next described, but the mouth is smaller.

* MACROCEPHALUS; blunt-headed Cachalot. This has no dorsal fin, but the fistula is on the neck. This is one of the largest species of whales, often measuring sixty feet. The head is of an enormous size, constituting more than a third of the animal; the mouth is wide; the upper lip rounded, thick or high, and much broader than the lower, which is of a sharpish form, sitting as it were into a longitudinal bed or groove. The teeth that are visible are situated only in the lower jaw, and, when the mouth is closed, they are received into so many corresponding holes or cavities in the upper; they are numerous, rather blunt, and of a conical form, with a slight bend or inclination inwards. The

front of the head is very abrupt, descending perpendicularly downwards, and on its top, which has been improperly termed the neck by some authors, is an elevation or angular prominence containing the spiracle, which appears externally simple, but is double within. The head is distinguished or separated from the body by a transverse furrow or wrinkle. The eyes are small and black; and the ears or auditory passages extremely small. About the middle of the back is a kind of spurious fin or dorsal tubercle, of a callous nature, not moveable, and somewhat abrupt or cut off behind. The tongue is of the shape of the lower jaw, clay-coloured externally, and of a dull red within. The throat is small; the body cylindrical beyond the pectoral fins, growing narrower towards the tail. The colour of the whole animal is black, but as it grows old it becomes whitish beneath. It swims very swiftly, and is said to be a violent enemy to the white shark. (See SQUALUS.) The Greenlanders use the flesh, oil, tendons, &c. in the same manner as they do those of the Narwhal. (See MONODON.) This species of whale is reckoned difficult to catch, being very tenacious of life, and surviving several days the wounds that it receives from its pursuers. It has a vast cavity within the upper part of the head, in which spermaceti is found. This, when fresh, is nearly fluid; but when exposed to the air it concretes into opaque masses. The celebrated perfume ambergris is found in masses in the intestines, being the fæces of the whale when it is sick. (See AMBERGRIS.) The three varieties of this species are; 1. Black; back gibbous. Found in European seas. 2. Blackish-ash, with a gibbous back, which inhabits the coasts of New England, and is from sixty to seventy feet in length. 3. Whitish, with a smooth back. This last is found in Davis's straits, is only about fifteen feet long, of a yellowish-white; teeth a little incurvate, compressed, rounded at the tips.

* MICRONS; Sharp-nosed Cachalot. The dorsal fin of this species is long; and the upper jaw is longer than the lower. There are two varieties; in the first the teeth are sharp and hooked; it is about seventy feet long, is of a dark tawny colour; has forty-two teeth round, a little compressed; dorsal fin long and sharp: in the second the teeth are sharp and straight; this is from eighty to one hundred feet in length; the upper parts are blackish, and beneath it is white; it has a high bunch on the upper part of the back; the fin is near the tail; the eyes are bright yellowish; the tongue small and acute; the teeth are set in the jaw like a saw. This species swims swiftly, and is said to be a great enemy to the porpoise, which it pursues and preys upon.

* TURSIO; High-finned Cachalot. This species is particularly distinguished by the great length and narrow form of its dorsal fin; the teeth are flat at the tip. This is said to be sometimes one hundred feet in length; at a distance the dorsal fin has the appearance of a mast of a ship. It inhabits the Northern ocean.

PHYSIC, or PHYSICK, φυσικη, the art of healing, properly called *medicine*.

The word is formed from φυσικη, nature; because medicine consists principally in the observation of nature.

For the rise, progress, division, &c. of physick, see MEDICINE.

PHYSIC, *Hermetical*. See HERMETICAL.

PHYSIC, *Bachelor of*. See BACHELOR.

PHYSIC Nut, in *Botany*, the name of a species of the jatropa. See CASSADA.

PHYSICAL, φυσικος, something belonging to, or really existing in nature.

In this sense we say, a physical point, in opposition to a mathe-

PHYSICAL EDUCATION.

mathematical one, which last only exists in the imagination. Or a physical substance, or body, in opposition to spirit, or metaphysical substance, &c.

PHYSICAL or sensible horizon. See HORIZON.

PHYSICAL agent, cause, certitude, concrete, continuity, evidence, fate, good, liberty, necessity, part, perfection, possible, pre-determination, promotion, qualities, and quantity. See the several substantives.

PHYSICAL Education, is that branch of education which respects the care and culture of the bodily powers, considered in reference to their subserviency to the mental powers, and the influence of the state of them upon the mind. As we have already observed in EDUCATION, the organs of sensation must have vigour and sensibility, in order to bring the system of thought and feeling into its due state of perfection, both as to comprehensiveness and vigour, and as to proper direction: and much of intellectual improvement and moral culture depends upon the state of the muscular and nervous system in general. The education of the human being, as far as respects these objects, may be termed *physical*; and by physical education, therefore, we understand that series of means by which the external organs of the mind, the organs of sensation, and the muscular and nervous system, so far as the mind is directly concerned in their operations, are to be preserved in a sound and healthy state, and improved in activity and vigour.

When we consider the influence of the body on the mind in its greatest extent, we are fully aware that whatever affects the health and vigour of the body, may, with strict propriety, be regarded as an object of education; and in this point of view, the whole treatment of infancy, childhood, and youth, in respect to health, whether its continuance or restoration, might properly come under the head of physical education. But in the article above referred to, we expressed our intention not to encroach upon the science of pathology; it would lead us into a field by far too extensive for our limits, without affording any material aid in the object we have in view. The judicious mother may learn much from books on the diseases of infancy and childhood, which will operate by way of caution and prevention; but we strongly recommend her not in general to undertake herself the management of those diseases, but to obtain good medical advice. We do not doubt that the parent who has a tolerable acquaintance with the nature of the bodily constitution, and has had the advantage of much experience and observation, will often be the best physician for her children: but there are few who would not be benefited by the advice of others in all cases which may permanently affect the health; and, in general, by far the safest and best way is, early to call in that aid which medical skill may sometimes effectually afford, without tampering with the constitution by the use of powerful remedies, or even of common ones too frequently. Still, however, we are satisfied that the judicious mother may derive from books much important information respecting the medical treatment of her children, particularly in the early periods, and in the way of *prevention*; and we may be allowed, as we go along, to recommend one work which we have reason to believe of great value, *viz.* Underwood on the Diseases of Children. In mentioning this, we are at the same time aware that much that is valuable may be derived from Mofs, Hamilton, &c.

While we are referring, as we frequently have done in the preceding articles on this subject, to the mother's share in early education, we feel astonished that the most important objects of female education are so much neglected. Were they generally educated with a specific view to their afterwards filling some of the most important relations of

domestic life, the next race, or, at farthest, that which follows, would be, without example, wise and good. If such were the views adopted in education, it would then be a primary object to cultivate their *understandings*; to give them solidity, accuracy, and comprehensiveness of judgment; and to store their minds with that correct and important information, which would enable them, in their turn, to train up their own offspring, or the offspring of others, in that way which would give them the greatest probability of being vigorous, healthy, and active in their bodily powers, and lay the best foundation for intellectual and moral excellence. A woman may not be a wife or mother, but she can scarcely fail, if properly prepared for those relations, to be led, in some way or other, to fill situations in life, bearing considerable resemblance to them in their effects on the improvement and happiness of others.

In MORAL Education, col. 1—3, we have referred to the intimate connection which exists between the cultivation of the moral and intellectual powers. In fact, neither can be neglected without serious injury to both; though the influence of moral education upon the culture of the understanding, is decidedly the greatest and most extensive. Physical education, in like manner, bears a close connection with the other branches; and, indeed, it lies at the foundation of both. But it can seldom, if ever, be necessary to make it an object *altogether* independent of the culture of the mind; and if pursued solely in reference to the animal health and strength, there is no doubt that the seeds of their destruction will often be sown, by the very means which are employed to promote them. This is a truth which may, at first sight, appear rather paradoxical; but we leave it, with full confidence, to the consideration of the judicious observer, who will find it more particularly true with respect to boys. We are perfectly disposed to admit that the care of the bodily health should be a primary object in the early periods of education: and we are certain, that by making this, in a proper manner, a primary object, the ulterior ends of education will be best accomplished: but then it should be pursued with a view to those ends; and if it be not, it will itself, in all probability, defeat its own purpose. An unrestrained mind in a vigorous body cannot fail to be eventually a slave of the body. In subsequent periods of education, mental and moral culture may, and must be, the leading objects; but they too will, in a considerable degree, defeat their own ends, if pursued without reference to the bodily health and vigour. We would by no means intimate that debility of body, or extreme physical sensibility, is *necessarily* attended with ill effects on the moral and intellectual system. Under judicious management, they often have led to high degrees of moral worth, and have not prevented very great progress in mental culture; but their general tendency is, on the one hand, to produce debility of mind, and the moral qualities connected with it, cowardice, meanness, &c.; or, on the other, that extreme insensibility which will either speedily consume the powers of body and mind, or sink into selfishness of the most injurious kind, because it often wears the garb of benevolence.

Whatever be the nature of the immediate organs of the percipient principle, there can be no doubt that they depend greatly upon the bodily system. Whatever be the nature of the organisation upon which sensation, retention, association, memory, and imagination depend, it is indisputable, that it is most intimately connected with the material organisation which is connected with any of the operations of the mind. As far as the judgment depends on these subordinate powers, this also must be affected by whatever affects them. Taking the term in its widest sense, the
memory

PHYSICAL EDUCATION.

memory is necessary to the judgment; it supplies it with its materials for discrimination, comparison, &c. so that without it there could be no exercise of judgment; and if there be a deficiency in the calls for this exercise, whatever "high capacious powers, lie folded up in man," however great the natural capabilities of the mind, they never can be properly and fully evolved. That the elementary powers forming the memory and imagination, are very greatly dependent upon the body, is a point so well ascertained, that we may assume it as a fundamental position; and the close connection, therefore, between the culture of the understanding and a sound and vigorous physical system follows at once as a necessary consequence.

We consider it as an established truth in mental science, that sensations are the rudiments of all our mental pleasures and pains, and also of all our intellectual ideas, except those immediately derived from consciousness. The reader of the article *Mental Philosophy* would perceive that we do not neglect the direct influence of the understanding in aiding, modifying, or restraining the operation of the associative power on the relics of sensation: but however great this influence, the above statement is no less true; and we think it an important truth. We have, however, already said enough on this fundamental position in the first division of *Intellectual Education*, and near the beginning of the second in *Moral Education* (see also *Mental Philosophy*, Div. II.): and we shall, therefore, only add here, that the business of physical education, as we have defined it, is, to keep not only what are generally known by the appellation of the external organs of sensation, but the whole muscular and nervous system, in a sound and vigorous state, or to bring it into that state, and this not only with a view to the health of the body, but also to the intellectual and moral welfare,—in other words, to the worth and happiness of the individual.

The capacity of sensation may, no doubt, depend upon the peculiarities of the mind itself, of the percipient principle (whatever that be); but without resorting to an opinion which probably can never be proved, we see enough in the diversities of the bodily organs of sensation, taken in all its varieties, to account for all the known diversities in *sensation*, (considered of course as distinct from perception); and we, therefore, do not hesitate in the belief, that this elementary principle of the mind depends upon the corporeal system. How far this is the case with respect to association, considered as distinct from sensation and retention, we have no certain means of ascertaining; but various facts lead to the belief that it is to a very great extent. The power of retention, there can be no doubt, depends greatly upon the state of the corporeal system; and, indeed, the statements of different writers respecting the influence of the bodily state on the memory, may be applied partly to the associative power, and partly to the power of retention. Altogether, however, there is no room for reasonable doubt, that the elementary powers of the mind, by which almost the whole of its furniture (of intellect and affection) is acquired, depend in their original operation upon the state of the physical system, and are modified by it through life. Indeed there are few who by the influence of external causes or of their own voluntary efforts, are able to cement that influence.

We are fully satisfied that there are decided original differences, not only in the powers of sensation, retention, and association, but even in the judgment; and probably the three former are, by their very nature, directly dependent upon original peculiarities of the physical organization, the varieties of which, if we may judge from external appear-

ances, are indefinitely great. But we see no reason to doubt that the defects or exuberances of all of them, may be considerably, though not entirely, corrected by direct or indirect culture; and that this must be done, in the first instance, by means of physical education. If there be an excessive degree of physical sensibility, the object must be to lessen it. In all probability, when the body is healthy, there seldom, if ever, is too little, as far as respects the mere capacity of pleasure and pain; but in reference to the acquisition of intellectual ideas, the organs of sensation often admit of great improvement in the power of receiving and conveying to the mind the rudiments of knowledge. However, the grand point is, if possible, to make and preserve the body sound and vigorous, in that state in which "life is felt in every limb:" presuming that the influence of this state upon the mental and moral powers, if accompanied with a proper attention to their culture, cannot be otherwise than beneficial; and that the contrary must often be highly prejudicial: directing the attention to the supply or correction of the influence of the body on the mind; and in all instances aiming to make the degree of muscular or nervous health possessed, as beneficial as possible in its effects on the internal furniture of intellect and affection.

Considering the mutual dependence of the body and the mind on each other, and (from the little which we have stated on the subject, and other circumstances which will readily occur to the intelligent reader) the intimate connection which exists between physical, and intellectual, and moral education, it will scarcely be expected that we shall be able to draw a minute line of distinction between these branches of our subject: indeed we shall find it less practicable here than in our former articles, (in which, however, greater minuteness than our plan admitted, would have brought their connection more forcibly into view); nor shall we attempt to preserve such distinction. Our leading object will be,—the education of the body; but as it should always be pursued with a view to its influence on the happiness, and on the development and culture of the intellectual and moral powers, we shall take it without any very nice discrimination, which in our apprehension would be wholly useless and impracticable. In several instances we shall be led to state considerations most closely affecting moral education, in consequence of their intimate connection with our immediate subject; but we doubt not that, in general, this will be seen to be predominant in almost every portion of this article.

The great point clearly is, to preserve, or to produce, that health and vigour of the bodily system in general, and that soundness and susceptibility of the organs of sensation, which powerfully contribute to intellectual and moral improvement, as well as to the happiness and usefulness of the individual.

We shall not find it necessary to enter very minutely into detail on the means by which these objects are to be effected. The education of the body, where there is no excess of refinement, or perversion of false philosophy,—where, in short, it is left to the guidance of good sense under the influence, not of parental anxiety but of parental care,—can seldom fail, in ordinary cases, if the basis of a good constitution previously exist, to go on successfully: and in extraordinary cases, it requires the aid of what we cannot attempt to supply,—medical skill. Much information, too, may be derived from books which are accessible to most parents; and as we are more desirous of making our pages the vehicle of useful truth, than of striking novelties, we shall freely avail ourselves of that information, where it appears to us just and important. In this object we have found a work, entitled "The Parent's Friend," of considerable service; and as we were not acquainted

PHYSICAL EDUCATION.

acquainted with it when drawing up our former articles, we wish now to introduce it to the notice of our readers. It consists of "extracts from the principal works on education, from the time of Montaigne to the present day (1802), methodized and arranged, with observations and notes by the editor." As the opinions adduced are sometimes in direct opposition to one another, and still more frequently in their connections and consequences, it may perplex those who are not accustomed to think and judge for themselves, but to those who are, it will afford many useful hints, and much valuable information; and by observing the variety of opinions on subjects, which, at first sight, may appear of obvious and easy decision, it will lead to more extensive examination, and leave the mind more free from the undue influence of authority, in a case in which the judgment alone should have the predominancy. We shall be indebted also to that singular work, "The Light of Nature pursued," and though we know not how to give an indiscriminate recommendation of Dr. Beddoes's *Hygeia*, yet we cannot doubt that the judicious parent may derive from it, as we have done, many valuable observations, which may be of singular use in the work of physical education. In one division, Dr. Currie's Medical Reports will supply us with some very important observations. When we have made such use of any of these writers, as appears to require acknowledgement, we will specifically refer to them.—We will begin with the following quotation from Search, which will give the reader a specimen of the author's peculiar style (see *Mental PHILOSOPHY*, near the end of Div. I.), and at the same time convey some very useful principles in the conduct of this and other departments of education.

"It is very material whether this principle (parental affection) be left to operate at random, solely by its own impulses, or guided by judgment and discretion. If due consideration be had," children "will not be regarded merely as play-things for the parents to divert themselves with, or shew about among their friends and visitors, to remark how tall, how lusty, and how lively they are; but as an important charge committed to our hands, as our nearest neighbours, whose fortune in this world and the next depends upon our management; which, therefore, deserves to be esteemed a serious affair, and be made the object of our constant attention. For the constancy of the application is of more consequence than the vehemence of it; as a little negligence or indiscretion will overthrow the good effects of many cares. People are apt to be prodigiously anxious for their children by starts, just when it comes strongly into their heads, and then think no more of them for long intervals afterwards. In their serious moods they collect treatises of education, in hopes to find a secret there for becoming excellent managers by the bare perusal; but these aids at most can only direct them, in some particulars, how to apply their industry, but can never infuse it: they must draw this principle from their own fund, and have gotten an habitual diligence, before they become qualified to reap any benefit from the observations suggested to them. *It is not a set of rules, how complete soever, but a steady vigilance and readiness to seize every opportunity of practising them, that must do the work.* Where there is the latter, it will go a great way towards supplying deficiencies in the former: for we see people, with very little knowledge or judgment, succeed well enough for common use, by an assiduous application of such judgment as they have; and there are more errors committed in the world through negligence than ignorance."

We fully agree with this singular writer, that the physical education of a child may be considered as commencing even

before its birth. How his moral welfare and happiness are affected by his being the offspring of an illicit connection, the reader may see well delineated in the *Light of Nature* pursued, if his observation do not furnish him with abundant proof. This we shall not extract or abridge, but will quote another passage, bearing more directly upon our immediate object. After having made some excellent observations on the duty of exercising prudence in forming the conjugal relation, and of giving some little consideration "what other parent we give our children, upon whom their future health of body and mind is to depend jointly with ourselves," he proceeds: "But happiness is made up of many ingredients, requiring forethought to provide for them; and if any principal ingredient be wanting, it will render all the rest of no avail: therefore, it is a cruelty, or at best an unpardonable negligence, when people entail diseases, diltemperature of brain, weakness, or poverty, upon their offspring, by unsuitable matches, or provide them with a parent who knows nothing but trifling dissipation and amusement, incapable of steadiness, or consideration, or of helping them either by instruction or example. This is sacrificing their children to their own fond fancy, or the glare of riches and splendour, whichever of the two idols happens to possess their imagination." He does not expect that every thing could be exactly according with our wishes, nor pretend to determine to what point precisely the interest of the parties is to give way to that of their probable offspring; but maintains that this ought not to be overlooked, as it so frequently is, especially by very young persons. "And if such weight has been given," he continues, "in making the connection, I presume it will not cease to operate afterwards during the time of gestation; but the mother will abstain from such intemperances, diversions, and hazards, as might prove hurtful to the burden she bears, preserving such a steadiness and sobriety of temper, as may secure her against frights and longings; and the father will strive to ward off whatever might excite any turbulent passions, or urge to any improper exercises, which would disturb the vegetation of the growing plant, or vitiate its juices." During the period of gestation, the mother ought, in the most careful manner, to avoid every thing which may produce bodily constraint, such particularly as tight and cumbersome dresses; all the productions of the tyrant fashion, which tend to impede the free development of the fœtus, as well as to render delivery more difficult. She should, for a similar reason, avoid every kind of agitating exercise, such as riding in carriages with rapidity on uneven roads, dancing, lifting or carrying heavy loads; in short, all fatiguing employments whatever.

Among the predisposing causes operating powerfully to check the processes of physical education, may be mentioned early marriages; where the mother, especially, is not arrived at that period of bodily vigour, which may give her offspring a common chance for health, nor her mind at that period of maturity which may enable her, with advantage, to discharge the duties of a wife and a mother. "Be silent for two years," is somewhere mentioned as the judicious advice of a young lady to her lover; and it would often be indeed for the happiness of the parties, as well as for the welfare of their families, if this were given, with the specific view above referred to. If affection would not stand such a trial, neither in all probability would it the trials of life.

In the remaining part of this article we shall endeavour to bring, what appears to us of chief consequence in physical education, under the following divisions:

I. *Air, Temperature, &c.*

II. *Cleanliness, Bathing.*

III. *Clothing.*

- III. *Clothing.*
- IV. *Beds, Sleep.*
- V. *Bodily Shape.*
- VI. *Diet, &c. Temperance.*
- VII. *Muscular Exercise.*
- VIII. *Exercise of the Senses.*
- IX. *Sensibility.*
- X. *Purity.*

I. *Air, Temperature, &c.*—Almost every one now knows, that the atmospheric air consists principally of two parts, one of which, oxygen, is essential to the support of life; that if this were in too great abundance, life would be spent too fast; but, on the other hand, that when there is not a sufficient quantity, (when, for instance, it has been consumed by flame, or by respiration,) the animal system cannot derive, from the portion of the atmosphere which is inhaled, that supply which is requisite to preserve it in a healthy state. In close rooms, where there is a fire, and perhaps several candles, and many persons at the same time consuming the oxygen of the atmosphere, there cannot be a sufficient quantity for the proper supply of each. If the external air is introduced in any considerable quantity into such rooms, unless due means are taken to prevent its proceeding in a current, the effect is usually highly injurious, by the rapid subtraction of heat from the persons who are within the current. In rooms which not only are not properly ventilated, but are also exposed to noxious vapours of any kind, it is impossible that health should be preserved or regained. One kind of air, (carbonic acid gas, or fixed air,) which is produced in great quantity by the burning of charcoal, is directly destructive; and if ever charcoal or coak are employed in rooms where there are children, though it would be better to avoid it in every case, it should not be without the utmost precaution, as the carbonic acid produced, if there be not a free circulation of air, will be in the highest degree deleterious, and probably fatal. Carbonic acid is produced by the burning of candles, and by respiration; so that by this means not only that part of the air is diminished, which is necessary for the support of life, but also another substance is added, which renders it more and more unfit for its object. These things are perhaps too little attended to, even by the well informed; by the ignorant they are altogether neglected. About nine or ten years ago, it was perceived that a lime-kiln, near one of the public medical institutions in Liverpool, (the infirmary, we believe,) was a cause of great inconvenience to the patients, whenever the wind brought the air from it towards the wards. As lime is employed, with so much advantage, for the promotion of health and cleanliness, it was thought a mere philosophical whim to suppose that the lime-kiln could be injurious. It was, however, prosecuted as a nuisance; and at the Lancaster assizes; the jury were convinced that it was so, by the intelligible, though philosophical, representations of Dr. Currie,—a man who united in a rare degree the talents for profound research, accurate investigation, and forcible, yet perspicuous, and even elegant expression; and whose name will long continue to stand high in the annals of philanthropy and medical philosophy. The well-known fact is, that when the lime-stone is being burnt, carbonic acid gas is expelled from it in great quantities, so as to diminish its weight nearly half; and it was this air which proved so unpleasent and injurious to the patients: on the other hand, the strong tendency of quick-lime to absorb carbonic acid from the atmosphere, is one principal cause of its salutary effects. One more circumstance we must mention in this connection, that carbonic acid gas, being considerably heavier than atmospheric air,

will, where it exists in any large quantity, sink to the bottom of the room; and on this account, the beds of children should not be placed on the floor. On the other hand, as heated air and (as it appears) noxious effluvia are lighter than pure air at a lower temperature, the most wholesome air will be found somewhat below the middle between the floor and the ceiling. It is from the effect of heat upon the gravity of the air, that a fire, with a moderately open chimney, is productive of very valuable effect in producing a considerable circulation of the air, and carrying off that which has been already deprived of its oxygen. There can be no doubt, that a room warmed with a close stove, other things being the same, cannot be so healthy as one with an open chimney; and it is, therefore, probable that the recently introduced register-grates, where the opening is but just sufficient to receive the smoke, will have no beneficial effect upon the health, though they may be more economical of fuel. In rooms for children, the due medium should be observed; but the wider the chimney the better, so long as it does not cause currents of cold air in the room.

This should be carefully avoided, especially in the room designed for the habitation of an infant. Violent inflammatory complaints are often produced by inattention to this circumstance. Among the poor a breach in the window, or a fissure in the wall, opposite the spot where the infant is usually held, have been attended with serious consequences of this nature; and the same thing has occurred in opulent families, by the shrinking of the sash frame or a board in the floor, or of some other wood work, which has admitted a strong but unperceived current. "The fire-place should be contrived that even in cold weather a steady temperature of about 60° may be kept for the first four or five weeks after birth. The air of the nursery should not be suffered to be below 50°." The heat should be regulated by a thermometer. If the use of such an instrument be not thought superfluous in a hot-house, for the purpose of securing the well-being of an exotic plant, it should not be thought unnecessary for the regulation of the temperature in which a little being is to be situated; equally tender with an exotic plant, arrived from as warm a climate. Few fathers, when once convinced of the propriety of a *steady mild* temperature, will hesitate to dedicate their most suitable apartment to the health of their offspring. Small nurseries cause many complaints, and many bad constitutions. If the door is kept partly open for the purpose of admitting air, the current is great and injurious; and a fire somewhat too brisk, produces a degree of heat which will aggravate some diseases, and greatly enervate a habit constantly immersed in it. (Beddoes, *Ess. v.*) Here, and in some other instances, in abridging from Dr. Beddoes, we have availed ourselves of the abstract in Dr. Stock's valuable *Life of Beddoes*.

The motion given to infants should at first be gentle, on account of the extreme susceptibility of the membrane which lines their nostrils and air-passages, (the mucous membrane.) It produces a considerable irritation which keeps up the susceptibility of the membrane; and this sometimes lays the foundation of asthma at a very early age, and more frequently a propensity to colds. The use of the cool bath at first, and afterwards of a cold one, is the safest and most effectual method of diminishing this extreme susceptibility, and of habituating the whole body to variations of temperature. For a new-born infant Dr. Beddoes prefers immersing up to the neck in water at 88°. "In a week the temperature may be reduced to 75°, and progressively to 60°, at which point we may stop for a twelvemonth." The severe discipline of washing in spring

PHYSICAL EDUCATION.

water, of the natural temperature, should only be gradually resorted to, and never until the strength of the infant is sufficient to resist its chilling influence. When the skin is in a hot and dry state, the body may then be bathed with advantage in tepid water; or the child should be taken into a room without a fire, and gently carried about till it returns to its natural temperature. This, when there is no feverish disease, will soon happen. The same plan should be pursued when it is hot, restless, or uneasy at night, for which purpose it should be taken out of bed. On the other hand, when the extremities are cold and clammy, gentle friction before a moderate fire with the hand, or with a soft flesh brush, is recommended, with the internal use of small quantities of thin animal broth, a little above blood heat. To this, immersion in a warm bath at 96° may be added, and repeated, if occasion require, four or five times in the day. Beddoes.

In cold seasons, the removal of children into the open air should not be precipitated. It is better to be content with habituating them to those variations of temperature which different rooms in the same house will at first supply. They should not at first be carried into the cooler room, except when they are rather warm, and then only for a short time. Where likely to be met by streams of air, the whole head should be covered, allowing sufficient breathing room. They should be rendered hardy, by exposure to a cold calm atmosphere, for a short time at first, and at no time till they are chilled. They should never encounter rude blasts till they can move briskly enough to produce warmth from within, and then only at intervals successively prolonged. "The parents who feel a just confidence in the robustness of their offspring, will do no injury by proceeding with a measured pace. We have access to no river Styx, in which one immersion shall render us invulnerable to the elements." The superiority of those who have been accustomed to face the severest variations of temperature, to the "inactive fire-side tenderling" in vigour and health, would naturally enough lead to the supposition,—that to endue a young person with these desirable qualities, nothing more was necessary than to expose him sufficiently to the cold. From this prejudice many constitutions have sustained irreparable injury. The true principle is, *gradually to inure the habit to cold*; and a good constitution may thus be enabled to bear severe and long continued cold without detriment: but *as soon as a chill comes on, the process should be suspended*; for in the strongest constitution, "long continued and repeated chills will, in the first instance, enfeeble, and, in the second, bring on a susceptibility to the operation of the powers that superinduce violent diseases." Beddoes.

One great source of injury from diminished temperature, is to be found in the custom of bathing or swimming, when too long protracted: but some remarks on this head will come more properly under the next division.

A grand cause preventing that invaluable state of the bodily system, which we will term hardiness, is the dependence placed upon external warmth for producing a comfortable state of sensation. It is a fact incontestably proved that the continued application of external warmth renders the living system less capable of being called into strong, healthy, or pleasurable action. Every muscle steeped in a heated medium, loses of its contractility: every nerve grows languid; and when excited, acquires a disposition to throw the moving fibres with which it is connected into convulsive movements. Instead of accustoming our children therefore to heated apartments, from which every breath of air is excluded, we should lead them to seek for warmth

by exercise, or provide them with it by that kind and degree of clothing which will confine the animal heat, and thus in reality encrease it. Beddoes.

Till hardiness has been acquired, and perhaps even after, sudden variations of temperature can scarcely fail to be attended with injurious effects upon the bodily system. This is the chief cause of colds, or catarrh. The inflammatory species of catarrh are not simply owing to cold, but arise from the concurrent or successive action of cold and heat, or of stimuli equivalent to heat. If the cold to which the system has been exposed was considerable, heated apartments and warm spirituous liquors concur in carrying inflammation to its just height. It is well known that frozen limbs will inflame so as to mortify, if they be not carefully kept from the contact of mediums which are considerably above the freezing point; and the remedy is to rub them with snow. When the mucous membrane has been chilled by frosty air, it is reasonable that a similar method should be adopted,—gentle exercise in an atmosphere not much exceeding the temperature by which it has been chilled, and the avoiding for the day all kinds of heating liquids. Beddoes.

The beneficial effects arising from the exposure of the bodily system to the external air, separate from those arising from exercise, are, in the first place, supplying it with air containing a due proportion of oxygen, which can seldom be obtained in rooms constantly inhabited by several persons unless thoroughly and frequently ventilated; and next, taking away a portion of the superfluous heat from the body. Hence, though exercise within doors is much better than no exercise at all, yet the bracing invigorating effects of the external air can seldom be thus obtained, and indeed never, except in a cool room kept well ventilated. When children, therefore, have sufficiently gone through the hardening process to bear it, they cannot be too much in the external air, as long as they are free from chilliness. The dry cold easterly and north-easterly winds, and the dampness so frequently in our climate, on the one hand, and the excessive heats of summer on the other, should certainly excite the parent's caution; but when the air has sufficient coolness in summer, and is sufficiently dry in the other parts of the year, almost continual exposure to it, with the above precaution, cannot fail to be beneficial to the constitution properly prepared for it. As the requisition of physical health should be the chief object of the first period of education, the parent should embrace every opportunity of giving his children the full benefit of this means of health.

Regularity in mental employments is of very great importance, and the habit should be early formed, but the requisite arrangements should be so contrived, as to interfere as little as possible with this most essential point.

It is a well-known and important principle of chemical philosophy, that solids when changing into fluids, and fluids when changing into vapour, absorb heat. And where this is not supplied with sufficient rapidity by the immediate cause of the fluidity or evaporation, the substance undergoing the change abstracts heat from all the surrounding substances, in other words produces a greater degree of cold. It is on this account that, though the atmosphere may be warm during a thaw, the body, when near the melting substance, generally feels chill; and that the same effect is experienced in damp weather, since the heat of the body produces a degree of evaporation from the damp on its surface; and the same effect is produced in a greater degree, and often without being immediately experienced, when wet clothes (the shoes and stockings for instance) are rapidly dried whilst they are worn, and at the same time the body not supplied

PHYSICAL EDUCATION.

plied with natural heat by exercise of any kind. Indeed there are few constitutions, unless they have gone through the processes of hardening to an uncommon degree, which can avoid being injured by this common practice. The intense degree of cold produced by evaporation, may be perceived by pumping on the hand, so as to have only an occasional stream of water upon it in different parts: if the hand were kept still in water at the same temperature, much less cold would be experienced. In like manner, if the lower extremities be placed in warm water, and the water be gently agitated, so as to expose part of the wet surface of the leg to evaporation, this part will be found very cold, while the rest is very warm. Those who are much accustomed to observe their sensations, may perceive that even when the water is still, if there be sufficient warmth to produce evaporation, the part of the leg immediately above that which is immersed, feels colder than the rest, nearly as though there were a ring of metal round it. Perhaps, however, the effect may be most completely perceived, by first standing a little before a quick fire, and then suspending close before one a piece of damp flannel; if sufficiently near, and the heat sufficiently strong to produce a rapid evaporation, the cold produced (in other words the loss of heat) will be very sensibly felt, and might be made evident by the employment of a thermometer.

By attention to this principle, parents will take care, if their children's clothes are wet, that they either keep in some degree of exercise till they are dry, or have them removed; that their skin is well dried after washing or bathing; that their linen is properly aired (not warmed, except for weakly children) before it is put on; and that no clothes should be put to dry in the room in which they live. Inattention to this last circumstance, in the nursery particularly, is a common cause of chill and colds among infants. When we consider, however, how little injury is experienced by alternations of heat and cold in the hands, or by their exposure to damp, how little, too, where the feet are continually exposed to them without the protection of shoes and stockings, and how frequent the circumstances in real life where some considerable exposure must be experienced; it is clear that caution should not be carried too far; the only point is that the hardening system be introduced by degrees, and that those degrees be determined by the previous state of the system, *i. e.* its capacity to endure them. To attempt to carry them on with a weakly child, as rapidly as with a healthy one, would be foolhardiness.

We referred in a preceding paragraph to the injurious influence of the easterly and north-easterly winds in spring. These are not only cold, but extremely dry; and by their dryness alone they must act as powerful refrigerants on moist surfaces. Their effect in producing this diminution of heat is proved by the following observations of the late accurate and ingenious Dr. James Hutton of Edinburgh. "I used to amuse myself in walking in the fields, by observing the temperature of the air with the thermometer, and trying its dryness by the evaporation of water. The method I pursued was this: I had a thermometer, included within a glass tube, hermetically sealed; this I held, in a proper situation, until it acquired the temperature of the atmosphere; and then I dipped it into a little water, also cooled to the same temperature. I then exposed my thermometer, with its glass case thus wetted, to the evaporation of the atmosphere, by holding the ball of the thermometer, or end of the tube, in which the ball was inclosed, towards the current of the air, and I examined how much the evaporation from that glass tube cooled the ball of the thermometer which was included. During the summer season, in the driest weather that I

could find, I never sunk the thermometer in that manner, to the best of my remembrance, above two, three, or four degrees. But in a cold east wind in the spring, I once sunk it between nine and ten degrees. It was, I believe, about the month of March or April; the sky was cloudy above, and no sunshine, and the wind was cold to the feeling, steady blowing, but not strong." Hence we perceive, that the superior dryness of the air in March makes moisture evaporate faster than the superior heat of the summer air: and this is independently of all sunshine. It is evident the surfaces along which the dry cold air passes in breathing, must be affected in the same manner as the surface of the wetted glass tube; and these surfaces thus cooled, will be ready to be thrown into intense action by the rays of a powerful sun in a fluctuating spot, or beside a brisk fire at home. Beddoes.

If circumstances require exposure to the external air in such circumstances, before the general system is properly hardened, a simple expedient which Dr. Beddoes recommends to adults, where there is a disposition to catarrh, may be employed with great advantage; *viz.* to place a sufficient number of folds of gauze or muslin over the mouth and nose; it will not only warm the air before it enters the respiratory passages, but likewise give it moisture when the air is dry as well as cold. There are probably few travellers who have not experienced the beneficial effects produced by fastening their comforters over the lower half of the face.

II. *Cleanliness, Bathing.*—We persuade ourselves that it cannot be requisite, in the present day, to urge upon parents the necessity of the strictest attention to the cleanliness of their children. The old maxim, "cleanliness is next to godliness," has a degree of truth, in a moral as well as physical point of view, which it may require some experience in life to perceive, but which observation will completely prove to all who will not absolutely close their eyes to what passes without them. A want of cleanliness is almost universally united with carelessness and indolence. It renders the body susceptible of infection, while the contrary practice affords the greatest security against virulent diseases. There can be no reasonable doubt that cleanliness is one grand cause why the rich escape so much more than the poor from infectious fevers; and that their prevalence and virulence among the poor, are, in a great measure, to be attributed to the want of it in their persons and in their dwellings, &c. Personal cleanliness, and cleanliness in the apartments in which children live, should be most strictly enforced; and such a regular system should be early adopted, as may secure this most desirable end. No day should pass, except when the bodily health is materially interrupted, without a complete washing, not only of the extremities, but of every part of the body; and if this cannot safely be done with cold water, it is extremely seldom that it may not with cool or tepid water. Children should be early accustomed to wash themselves, but it should be under careful inspection till they have completely formed the habit of doing it thoroughly; and when this is done, it will be as unpleasant to them to omit it, as to some it appears to be to make themselves clean. When past the early periods of childhood, it will often be impracticable to carry on the system of universal washing; but it should be made as general as possible, and for the purpose of cleanliness, as well as of invigoration, the bath should be employed as frequently as domestic circumstances, or the state of the constitution will allow: with respect to the former, by suitable management they might generally be made to bend to the latter.

Bathing certainly ought to be regarded as having a powerful efficacy on the system; and if its effects appear to

be injurious, before it is much persevered in, medical advice should be obtained. The advocates for *tepid* bathing seem to have great reason to recommend it as a valuable remedy, or even as a preservative in cases where the constitution is weakly, and has consumptive tendencies; but the facts which they adduce, rather prove it, we apprehend, to have a stimulating and relaxing influence, than an invigorating efficacy; and the warm bath at least should seldom be employed, except by medical direction, in reference to the particular case. As our present object is not the recovery of health, but the invigoration of a system which is at least tolerably free from direct tendencies to disease, we will leave the subject of warm bathing to the physician. No doubt cold also requires caution. Where the constitution has any direct phthical tendencies, or is peculiarly weakly, it would be rash to expose a child to it; but we cannot doubt that in other cases, cold, or at least cool, bathing, employed with precaution, and in that way which experience may shew to have the most beneficial effects upon the system, has a highly important effect in giving strength and activity, or in keeping up the tone and vigour of those who are already robust.

If the *cold* bath is employed, the system should be *gradually* brought to the capacity of bearing it. There are exceptions to the necessity of this rule: and amongst the ancient Germans, (as at present among the Russians,) immersion in cold water was employed in the earliest periods of infancy: those who survived the experiment were without doubt rendered more hardy by it; but in all probability, numbers sunk under it. It is an experiment which no parent ought to try, without a well-grounded confidence in the strength of his child's constitution; and as the same effects may be *safely* produced in a more gradual way, it seems to us a risk which few circumstances can justify.

We strongly recommend to the intelligent parent, the perusal of Dr. Currie's Medical Reports "on the effects of water, cold and warm, as a remedy in fever, and other diseases, whether applied to the surface of the body, or used internally." It is a work which can scarcely fail to afford a warm interest to any one accustomed to accurate observations and scientific researches. The 15th chapter, containing "an account of the remarkable effects of a shipwreck on the mariners, with experiments and observations on the influence of immersion in fresh and salt water, hot and cold, on the powers of the living body," must be regarded as a fine specimen of philosophical investigation; and a young person, properly prepared for it by previous information, would find it a highly useful study. We recommend this work to the parent, because he will find in it some highly important principles respecting the effect of water upon the animal system, which may be applied with great advantage in a state of health, and which, in those emergencies which sometimes occur in sickness, may be the means of preserving life in his family, or among his neighbours. To enable a person to employ these principles in cases of illness, he must study some parts of the work itself (see BATHING); but we shall select those which will prove of immediate importance in physical education. It is to be observed that Dr. Currie applies the term *tepid* to water heated to that degree which is warm, but not hot to the sensations, which, in the way of *affusion*, is from 87° to 97°. When the body is *immersed*, it may be applied to water some degrees higher. (Vol. i. p. 69.) "By the term *cool*," he afterwards says, p. 75, "I indicate from 87° to 75°;" and as this obviously refers to affusion, we may suppose that *cool* in *immersion* extends from about 82° to about 70°: but as far as the sensations are concerned, there is no doubt that great variation will be experienced from the comparative temperature of the air, and its bracing

effects on the system. The writer of this article recollects finding freezing water produce a sensation of comparative warmth, while immersed for a short time in it; and in the employment of a shower bath, in the winter months, has generally *felt* the water to be warmer in a cold frosty morning, than in a mild damp atmosphere, when the water itself must have been of considerable higher temperature. 1. The principle which Dr. Currie lays down respecting the use of the aspersion or affusion of cold water, in fever, will afford a good direction respecting the use of cool or cold bathing generally. It may be safely used, "*when there is no sense of chilliness present*, when the heat of the surface is steadily above what is natural, and *when there is no general or profuse sensible perspiration.*" (P. 17.) For our purpose, the second clause may be changed into—"when the heat of the surface is not lower than what is natural," and the whole will then form an excellent aphorism. 2. The following statement appears to us, from repeated experience and observation, to convey the precise effects of cold bathing, where judiciously conducted. After having expressed his opinion (p. 70.), that in some cases the heat is lowered more speedily by the affusion of tepid than of cold water, Dr. Currie adds: "the evaporation from the surface is more copious from the tepid affusion; and on this the cooling of the body very much depends. But this is not all. The tepid affusion is little, if at all, stimulating, and does not, like the *cold affusion*, rouse the system to these actions by which heat is evolved, and the effects of external cold are resisted." It is on this principle that Dr. Currie considers the tepid affusions as a valuable remedy, in a great part of the feverish affections of children. 3. Speaking of the effects of spunging or wetting the body with cold or warm vinegar or water (p. 73.), he says: "According to my experience, it is not only less effectual, but in many cases less safe; for the system will often bear a sudden, a general, and a stimulating application of cold, when it shrinks from its slow and successive application." On this principle, which we are satisfied from various considerations, is fully applicable to cool or cold bathing, we hesitate not to recommend immediate immersion, either by plunging in entirely, which, with care, can seldom be injurious, or getting in deep at once, and speedily covering the head with water; or, if the shower bath is employed, that the holes should be so large as to allow the water to come through rapidly. Experience will shew that this last precaution is of considerable importance. If the holes are small, the sensation is itself unpleasant and continued, and the partial evaporation often produces chilliness. When this is the case, bathing never can be beneficial. 4. The cool affusion "operates as a gentle stimulant, and may be used as a milder form of the cold affusion. Like the cold affusion, its application should be sudden and momentary, when the object is to increase the tone of the system, or to dissolve a morbid catenation. When it is employed to moderate inordinate heat, it may be used more slowly, provided it does not interrupt the catenation on which respiration depends." (P. 76.) We are not forgetful of the difference between the diseased and the healthy state of the body; but we see every reason to believe that this, and similar cautions, are applicable to both. 5. "The pernicious effects of cold water applied internally and externally, during profuse perspiration, depend upon the same causes, viz. that perspiration itself is a cooling process, under which, when profuse, the heat of the body, whatever its natural state may be, is sinking; that under such circumstances, we find, as a matter of fact, that it parts with its remaining heat more easily; and on the sudden application of cold, that this heat sinks to a degree which

which disturbs, and sometimes wholly interrupts the actions on which life immediately depends." The 12th chapter is one which cannot fail to be very interesting to the general reader. It is entitled "Of the disease that arises from drinking cold liquids, or using the cold bath after severe exercise;" and contains many remarks, which the classical student will find of advantage to him in his researches. Into these we must not enter, but confine ourselves to our present object; including, however, some positions more immediately respecting the use of cold water internally. The general fact is, 6. That the fatal effects proceeding from drinking cold water, in cases where the system has been extremely heated by bodily exertion, have occurred in circumstances, "where the system, after having been much heated and enfeebled by severe exertion, is losing its preternatural heat from profuse sweating, and in general also from the cessation of the exertions, by which this heat was originally produced. Here two powerful causes combine to cool the body; and if, under their operation, a sudden application of cold is made either to the stomach or the surface, the living power will, we know, resist it faintly, and the fatal consequences be accounted for." Dr. Currie then gives a number of cases, which should be read by the parent to his children, as soon as they are capable of fully understanding them, and afterwards brought back to their memory, as circumstances direct; and the same by the tutor to his pupils. And the parent and preceptor should be acquainted with one simple remedy, which, in cases where the injury has not been too great, may prove effectual in restoring vital heat, namely, "the application of a bladder filled with water, heated to 110° or 115°, to the pit of the stomach." 7. "There is no situation in which the application of cold to the body, whether to the surface or the stomach, is so safe, or in general so salutary, as when the heat of the body, from whatever cause, is preternaturally great; provided that the body is not already in a state in which it is rapidly parting with this heat, and no disease has taken place in the general sensibility, or in the structure of any of the parts; and that when the body is preternaturally heated, the degree to which cold water may be drunk may be always decided by the steadiness of the sensation of heat, and the tenacity with which the preternatural heat is actually retained. With this observation, however, must be connected another, "that the heat preternaturally accumulated by exercise is held with less tenacity than even the heat in intermittents. It is dissipated by the perspiration that exercise occasions; and is speedily lost, when to profuse perspiration is added a state of rest. It is then that a large draught of cold liquid is especially dangerous. But while the preternatural heat is sustained by continued exertion, cold liquids may be taken in moderate quantities, without producing any injurious effects. They may even, I apprehend, be drunk copiously, without producing suddenly the fatal effects already described: but in copious draughts, they are found oppressive to the stomach during exercise, and excite languor, nausea, and sometimes vomiting." Dr. Currie afterwards explains the difference between the influence of water taken into the stomach and used externally; which arises, he observes, partly from the weight and bulk of the fluid, particularly oppressive under the constant action and agitation of the voluntary muscles, and partly from the evaporation from the surface being promoted by the immediate access of external air. To these must be added another simple consideration, that where the external application is voluntary, it may be much more readily removed, and its injury checked, than where it is taken into the stomach; and this is of obvious import-

ance. "With these exceptions," he adds, "the operation of cold liquids on the stomach, and on the surface of the body, are analogous in the case of preternatural heat produced by bodily exertion, as in all other cases of preternatural heat. As it is safe to drink cold water, in proportion as the heat from exercise is great and steady; so also is it safe, according to this ratio, to pour it on the surface, or to immerse the body in the cold bath." 8. "In the earlier stages of exercise, before profuse perspiration has dissipated the heat, and fatigue debilitated the living power, nothing is more safe, according to my experience, than the cold bath. This is so true, that I have for some years constantly directed infirm persons to use such a degree of exercise before immersion, as may produce some increased action of the vascular system, with some increase of heat; and thus secure a force of re-action under the shock, which otherwise might not always take place. The popular opinion, that it is safest to go perfectly cool into the water, is founded on erroneous notions, and is sometimes productive of injurious consequences. Thus, persons heated, and beginning to sweat, often think it necessary to wait on the edge of the bath till they are perfectly cooled; and then plunging into the water, feel a sudden chilliness that is alarming and dangerous. In such cases, the injury is generally imputed to going into the water too warm; whereas in truth it arises from going in too cold. But though it be perfectly safe to go into the cold bath in the earlier stages of exercise, nothing is more dangerous than the practice, after exercise has produced profuse sweating, and terminated in languor and fatigue: because, as has already been repeated more than once, in such circumstances, the heat is not only sinking rapidly, but the system parts more easily with the portion that remains."

From the preceding observations it is obvious, that the cold bath should only be employed where the system has strength to stand the shock; and then its effects can scarcely fail to be beneficial, in invigorating the system, and preparing it to resist the influence of external cold. We recollect the case of a youth, of about 17, by no means of robust habit, and very liable to colds, who never was so little subject to them as during the winter, in which he persevered in the use of a cold spring water bath every other day. A walk of about half a mile to the bath prepared him for it: he undressed as quickly as possible, plunged once into the bath, and when well rubbed and quickly dressed, on his walk home, he had the most pleasing sensations of vigour and activity. As the system should be properly prepared for the excitement of cold bathing, we deem it an important precaution, at least for weakly children, not to employ it fasting. After a full meal, it can seldom fail to be injurious; but no time can be better than an hour or two after an early moderate breakfast. If this cannot be made convenient, a partial breakfast may answer the purpose. We observe this caution of experience given also by other writers on the subject. "I see no sense," says Dr. Beddoes, "in the common notion, that it is best to bathe with an empty stomach. I would not recommend the cool bath to a person full gorged; but it is desirable that the stomach should be in a state of gentle activity, as well as the external surface of the body."

Till the system has acquired considerable vigour, the cold bath should be employed solely with a view to its effects. Children, if the commencement of it is managed with caution, so as not to excite terror, will soon learn to like it, and would willingly stay in it. In summer, when the water has been exposed to the air, so as to acquire its temperature, this may be allowed, but rather sparingly. When boys

learn

PHYSICAL EDUCATION.

learn to swim, unless the water be too cold, the exercise they take in it will considerably check its injurious effects; but there can be little doubt that the practice, so common among boys, of going very frequently into the water, (two or three times in the day, for instance,) and staying there a long time, especially if not constantly employed there in active exertion, has ruined many a constitution. Till young persons have learnt that it is a part of duty, as well as prudence, to take care of their health, and have acquired the requisite information to prevent injury, bathing should never be practised except under the eye of some judicious friend. The morning is, on various accounts, the best time for this exercise, as well as for bathing in general; and more particularly because the system is not likely to have been exhausted by exertion and profuse heat, and will be able, by activity in the water, to keep off chilliness. After the first approach of this, no person ought to stay an instant in the water.

The temperature of the water must be an object of considerable attention and caution, before robust health has been obtained. No one can be ignorant that water from a slow flowing river, from the rapid shaded torrent, from an exposed cistern, or from the well or spring, differs very greatly in temperature; and upon the principle, which should not be lost sight of, of hardening the system by degrees, the parent will not begin with water at the lowest temperature, or near it, but go on gradually through different stages of temperature, carefully observing the effects of each, and varying from it accordingly. No precise rules probably can be laid down for this purpose; but what has been already said may serve for principles to guide the judicious.

The difficulty of domestic bathing, except for the very young, has often probably prevented the employment of it. We are fully satisfied that the shower-bath, which every one may have in some form or other judiciously employed, will not only answer the leading objects as well as immersion, but in several respects better. The principal cautions in the use of it, respecting the temperature, &c. of the body and of the water, are the same as those for bathing in its more common form. In addition to these, we recommend that the child stand upon woollen, at least not upon the metallic lining of the drawer, or the wet boards; that the height from which the water comes be not very great, in general cases perhaps a few inches is best; that it is so contrived that the water shall come freely and rapidly, when once the course is begun; and that the quantity be not very great. We perceive no advantage, in common cases, for more than a complete affusion. We are so fully impressed with the importance of this method of bathing, that we shall just give a plan for the most convenient kind of shower-bath. The height may be as great as the room will allow, for the purpose of filling, (say $6\frac{1}{2}$ or 7 feet.) The frame should consist of four stout pieces of wood, (say 3 inches by $1\frac{1}{2}$.) so connected that their outside edges may stand about 32 inches from each other at the floor, and 20 inches at the top. From about 10 or 12 inches from the floor, the bottom of the bath should begin to slope downward from each of the four sides, so as to form a square funnel, to convey the water into a broad, but shallow tub below. The funnel must of course terminate sufficiently far from the ground, to admit of the tub being easily removed. About two or three inches from the top of the funnel, some bars of wood should be placed across, on which a small board may be fastened for the bather to stand. The sides and door may be wood or canvas. The former is decidedly preferable; and a clever workman, in making it, will take care to have as

few obstacles as possible to the wet draining into the funnel, and that the joints are well made. We know of no better contrivance than the common top, a tin cylinder moving in a box, pierced with large holes at the bottom, about half an inch in diameter: this, however, need not be nearly so large as it is sometimes made. If the cylinder hold three gallons, it must in general be abundantly sufficient. A grown-up person can scarcely require more than two gallons, and a child of seven or eight not above two or three quarts. But the principal point is, that this top should be so contrived as to rise and fall within the case, for the purpose of adapting it to the height of the bather, and also for the convenience of filling it. Our experience leads us to conclude, that the use of shower bathing is much prevented by the difficulty of filling it, the want of care in its construction, the injudicious use of it, as to quantity, temperature, &c. and the damp chilliness of the place where it is usually kept; and we regret it, because, where the advantages of an immersing bath cannot be obtained, the shower-bath can seldom fail to be a most useful substitute, and often is decidedly preferable.

As to the comparative effects of fresh and salt water at the same temperature, we see reason to believe that the former operates simply by calling into action the animal powers of evolving heat, and by invigorating the surface: the latter has a decidedly stimulating effect, by its influence on the external vascular system. Sea-bathing has been often found to have a debilitating effect, where fresh water, at least in the shower-bath, has proved very bracing. Where the constitution is strong, there needs little attention to this difference; but among weakly children, sea-bathing should be regarded more than it is, — in the light of a medicine.

We have enlarged upon this point far beyond our intentions; but it appears to us of very great importance; and constitutes a very essential part of physical education. Some of the other divisions will admit of much greater brevity.

III. *Clothing.*—In our variable climate, considerable attention must be paid to the nature and degree of clothing, till a sufficient degree of hardness has been acquired to render such care almost unnecessary; it never can be altogether unnecessary, as long as the present habits of social intercourse are preserved, and as long as persons are subject to the debilitating influence of close heated rooms. But our observations chiefly respect the previous state, in which the system is going through the invigorating process, and among those classes of society where constant exertion in the open air is not employed. Exercise in the open air is undoubtedly the best means of producing animal heat, and next to that active employment within doors: but as this cannot be constantly going forwards, and continued, frequent, or great chilliness should be cautiously avoided, the clothing should be so contrived, particularly about the lower extremities, as to prevent the internal heat from passing off to the colder air. Preserving the internal heat by non-conducting clothing, such especially as woollen substances, is a much better preservative from chill, than the application of external heat. The temperature of the room in which children spend their time, should, if possible, seldom exceed 50° or 55° . It should be airy, dry, easily ventilated, especially at the top, but free from currents of air, and in order to procure warmth in cold or damp weather, sedentary employments should be continually mixed with exercise in which the extremities are employed. As it really is more difficult to provide exercise for the feet, and they are less employed in the usual occupations of education, it is desirable that they should not only be dry but well clothed; and
except

PHYSICAL EDUCATION.

except in summer, we can see no reason why warm woollen or even woollen stockings should not be used instead of the cotton clothing too frequently prevalent. If the feet are kept warm, the body will be usually found to take care of itself. Of course this and every other remark must be employed with judgment; but we are satisfied from observation and experience that it is the grand point. There can be little doubt that the general prevalence of slight dresses in winter, together with the absurd changes which are too often practised from warm garments in the morning to slight clothing in the evening and heated apartments, constitute one grand cause of the unhealthiness of that class of the female sex, who, unhappily for themselves, live in the walks of fashion. The general principle should be, to accommodate the dress somewhat to the season. Hardiness should be sought, rather by exercise, air, general attention to temperature, &c. than by sparing clothing. When it is acquired let experiments be tried; till then, parents will do well to give their children such clothing as, without being heavy, cumbersome, or heating, may prevent chilliness, both when engaged in domestic and even sedentary occupations, and when exposed to a cold atmosphere without. As to the employment of flannel under the linen, we think it of great service where there is a considerable tendency to chilliness and even to perspiration, provided it does not increase that tendency. But it should be as thin as possible; it should be frequently changed, and accompanied with a constant attention to the invigorating systems. And certainly it is not so desirable to begin a habit so difficult to break without judicious medical advice. Whatever additional clothing is employed for winter should be left off with caution, and not till the mild weather of spring, (if such there be in our climate,) is fairly set in. A real spring day has often tempted to leave off the winter clothing, and the piercing chill of the next day has caused serious injury. One further caution appears necessary; after great perspiration, unless the constitution is very strong, the damp clothing nearest the skin should be removed, and the skin well rubbed with dry flannel or rough linen.

From the first period of infancy the limbs should be allowed full play; and no excuse can justify the parents who, from a regard to the shape of their children, employ tight clothes, either about the body or the extremities. Modern fashion here, however, so much coincides with the sound dictates of physical education, that we need not enlarge upon it. There has scarcely been any improvement in dress more important than the use of loose trousers and suspenders, by which the weight of the lower parts of the dress is sustained by the shoulders, instead of throwing it, as we recollect it to have been, upon the hips, assisted by a tight bandage round the waist. Tight shoes and tight garters (which, if employed at all, should always be below the knee,) impede the circulation, and are followed by considerable injury to the lower extremities. In fact, the rule should be, to have every part of the dress not so close as to be cumbersome, but perfectly easy: and whenever children complain of uneasiness from their clothes, they should at once be rectified. No trouble or expence will in such cases be thrown away: there is nothing pays better in the long run than early care in the department of physical education. If half the pains and expence were employed in making dresses convenient and healthy, that are now given to appearance, it would answer every purpose.—We need scarcely add, that in the female dress the same principle should be observed; and except in cases where, from medical advice, a different plan may be thought necessary, nothing should induce a mother to allow her daughters any article of clothing whatever, which does

not give full and free play to the exercise of their muscles, or of the internal functions of the system. In the eye of reason that parent has much to answer for, who permits her daughters to use any article of dress causing compression about the waist; much in respect to the health of the individual; much, too, as it respects the health of her children, if she should be a mother, and her capacity to bring them into the world.

Attention to neatness and simplicity of dress should be produced, in the first instance, by parental care; and afterwards enforced by parental example and instructions. This is one of the external habits, which contribute greatly to the moral and even to the mental health.

IV. *Beds, Sleep.*—In the earliest periods of infancy it may probably, in many cases, be necessary to employ warm soft beds, at least during the winter season; but the sooner they can be dispensed with the better. There cannot be a doubt that soft beds have a very enervating effect upon the system: and that so far from contributing to the proper growth of the spine and limbs, they have a great tendency, by yielding considerably in parts, to produce distortion. The mattresses on which they lie should not, however, be so hard as not to yield at all. If hair mattresses, (which must be the best,) are not easily procured, they may be filled with wool or cotton flocks; the head should not be much raised; the child should be induced to lie sometimes on one side, sometimes on the other, and as little as possible we apprehend on the back. A moderate curvature of the body seems preferable to absolute straightness.

It does not appear undesirable to protect the *head* of the bed, especially if there be any danger of a current of air round the room; but nothing more than this. The habit of drawing the curtains close round the bed is highly prejudicial in confining the impure air, and producing an injurious degree of warmth. Proper provision should be made for moderate warmth, but care must be taken not to exceed it. "When young people," says Dr. Beddoes, "complain of unrefreshing sleep they should be examined in the night, and waked without compunction if found too warm. The bed clothes should then be thrown off, or if the dry heat be considerable it will be best to walk up and down the room in a dress which should be contrived for guarding the hands and feet from chill, while it suffered the trunk of the body to be freely ventilated." This may appear a precaution of some danger, as well as difficulty; and referring to an unhealthy state of the system, should not perhaps be adopted without medical advice; but on the following there can be no difference of opinion: "Whenever a person of feeble habit feels heated in a morning let him rise without a moment's delay." The heat of the bed is often increased considerably above that salutary point which at once imparts refreshment and vigour, and then produces fever, languor, and inactivity.

We have already stated in Div. I. that the bed should be raised from the ground, say 18 or 20 inches. As to the quantity of sleep, it must vary greatly with peculiarities of constitution. During the period of growth, if the temperature be not too great, and the room too confined, it is probable that eight or nine hours cannot be too much. Children under the age of eight or nine require an hour or two more. In the summer, however, less will be desirable; for the cool of the evening affords a valuable time for exercise, and the early morning air should not be lost. The middle of the day will then be found the best for rest, in circumstances which will not produce too much heat.

"There is an intemperance in sleep very necessary to be guarded against, because extremely apt to creep upon young people.

PHYSICAL EDUCATION.

people, especially in this cold climate, where it gives a smart pain to jump out of a warm bed into the winter air; therefore, this is a piece of hardiness which cannot be inculcated too early by all the means conducive thereto, whether advice, injunction, or shame. While under the eye of parents or masters, they may be kept constantly to a certain hour, which will make it the easier for them to persevere afterwards, when gotten from under that controul; if no disorder or accident intervene, they will need no more than one nap, which custom will have brought to terminate of itself just at the usual hour; and then if they turn upon the other ear to take a second, they should be taught to look upon it as an intemperance, not at all redounding to their credit. But this second nap is not so bad as lying awake, than which nothing tends more to foul the blood, to sharpen the juices, to exhaust the spirits, to unbrace the solids, to heat the blood, to stupify the understanding, to destroy hardiness, and to produce other inconveniences of very mischievous consequence. Let them seek their amusements elsewhere, but reserve the bed as a place appropriated to sleep and sickness; for if it were possible to live without either of those suspensions of the enjoyments of life, nobody would ever think of making a bed a part of his furniture." To make early rising pleasant and habitual, the first employments of the morning should be pleasant in themselves or their consequences.

The practice should be early begun, and afterwards adhered to as constantly as circumstances will permit, of sleeping singly. Separate beds are of no small service to the physical health; they are of essential importance to the moral health. To prevent departures from this plan, the beds of children and youth should be made as narrow as their comfort will allow, that they may not be used by two, without real inconvenience. If to this separation can be added that of rooms, no doubt the cause of morality must be greatly promoted; and this should be done wherever practicable, unless parents have full confidence in the delicacy of their children.

It may be worth while adding here, that suddenly awakening young children has often a very injurious mental and moral effect. Their first sensations should be pleasant, and we admire the principle upon which that mother proceeded, who always awoke her children with a song. Montaigne tells us, that his father always had him awakened by the sound of a musical instrument.

V. *Care of the Shape.*—The rest of bed is peculiarly necessary for children and growing youth, in order to afford a due degree of relaxation to the bodily system; and till the age of nine or ten, (and afterwards, if there be any marks of debility from ill health or too rapid growth,) children should be encouraged to lie down once or twice in the day, on the carpet or on pallets, in such a posture as may afford the greatest degree of relief to the muscles and joints. "When the least tendency to become awry is observed, they should be advised to lie down on a bed or sofa, for an hour, in the middle of the day for many months; which generally prevents the increase of this deformity by taking off for a time the pressure of the head, neck, and shoulders on the spine of the back; and it at the same time tends to make them grow taller. Young persons, when nicely measured, are found to be half an inch higher in the morning than at night; as is well known to those who enlist very young men for soldiers. This is owing to the cartilages between the bones of the back becoming compressed by the weight of the head and shoulders on them during the day. It is the same pressure which produces curvatures and distortions of the spine in growing children, where the bones

are softer than usual." Darwin on Female Education, p. 76.

Some remarks which might be applicable here will be found in Div. III., respecting the freedom which should uniformly be an object in dress; and we shall not therefore quote some good observations to that purpose, which we observe in Darwin, but must add his last sentence. "A wife fashion of wearing no stiff stays, which adds so much to the beauty of young ladies, has commenced since the above was written; and long may it continue." We are grieved to hear that this excellent custom is now (1814) very much laid aside; and that our fashionable young ladies have returned to the fashions of their grandmothers, increasing the injuriousness of their method, by making the pressure more partial. Report says, that even gentlemen now wear stiff stays. To them the injury is less, but not trifling. But this folly can only extend among those whom nothing but experience can cure of folly.

"All other methods of confining or directing the growth of young people should be used with great skill, such as back-boards, or bandages; and their application should not be continued too long at a time; lest worse consequences should ensue than the deformity they are designed to remove. Of these the stocks for the feet of children, for the purpose of making them turn their toes quite out, and the frame for pressing in their knees, as they stand erect, at the same time, I suspect, when carried to excess, to be particularly injurious, and to have caused an irrecoverable lameness in the hip-joint. These, therefore, should be used with proper caution, so as to give no pain or uneasy feels, or not used at all." (Darwin, p. 78.) "Instead of stocks, (says the editor of Parent's Friend, p. 56.) I would advise, that a straight line be drawn on the floor of the school-room, from one end to the other, and that sloping lines be drawn alternately on each side of it at equal distances. These lines should form angles of about 30 degrees (we should say 40° or 45°) with the centre line, and the children be daily accustomed to walk on it, placing their feet behind the sloping lines, so that the inside edge of the foot may exactly coincide with them. This would teach them to turn out both feet equally in walking, which they seldom do, and would give a regularity and steadiness to their gait, without which no one can be said to walk well.

"By confinement in a school room for many successive hours, and that without being suffered to vary their posture, some of the more active and lively children are liable to gain tricks of involuntary actions, as twitchings of the face, restless gesticulations of the limbs, biting their nails, &c. which are generally at first occasioned by the want of sufficient bodily exercise to expend the superfluous animal power, like the jumping of a squirrel in a cage; but are also liable to be caught by imitation of each other. To prevent this kind of deformity, children should be suffered to change their attitudes and situations more frequently, or to walk about as they get their lessons." (Darwin, p. 100.) The reader will find some useful observations on this subject in the chapter on Attention in Edgeworth's Practical Education.

VI. *Diet, &c.*—Under this head we shall not find it necessary to enter much into particulars. The food of children and youth should be nourishing but not stimulating; and as plain as can be. If their appetite be not pampered, or laid under unnatural restraint, it will generally be their safest guide as to quantity. We agree with Buchan, that the error of pinching children in their food, is more hurtful than the other extreme. The disorders of repletion are less injurious in their consequences than the diseases arising from

PHYSICAL EDUCATION.

the want of sufficient nourishment. Nature has many ways of relieving itself when overcharged; but long fasting is extremely hurtful to young people; and a child who is often pinched with hunger stands little chance of becoming a strong man. "The stomach (says Dr. Rush) is like an idle school-boy, when it has nothing else to do, it is always doing mischief." When children rise an hour and half or two hours before breakfast, we think it very desirable that they should be allowed a piece of bread and a draught of milk or water soon after rising; we have perceived considerable injury arising in the weakly stomach by early fasting. When they have gained some degree of robustness, this may be easily given up. It is highly desirable that the stomach be brought to the capacity of enduring great irregularity in the time of taking food; but in the early periods of invigoration, considerable if not minute regularity in the principal meals is very beneficial. When children fast too long they often do not know how to eat. In such circumstances, a small quantity of warm liquid will restore the disposition to eat, better than dry food. The principal meal should be sufficiently early in the day to allow of their taking out-of-door exercise after it. Perhaps it will generally be found, that about one o'clock is the best time for this; but it does not appear that a nearer approach to the common hour of dinner can be attended with any serious inconvenience, if the previous time be properly arranged for it. Though children should not get the habit of lounging at their meals, any more than at other things, yet they should not be hurried at them; but should be induced to eat their food slowly in order that they may masticate it properly.

We fully agree with Dr. Beddoes on the great desirableness of employing animal food in early childhood and ever after. Some speculatists have indeed attributed the prevalence of consumptive complaints, as well as suicide, in our island, to our free use of animal food; but it appears probable, in the first place, that much more animal food is eaten in countries where this fatal malady occurs less frequently than with us; and, in the next place, that a free use of animal food, instead of being objectionable, is highly advantageous as a security against its attacks. The salutary agency of animal diet in preventing the development of scrofula is now generally known; and the mistakes of those parents, who imagined that, by confining their children to a vegetable diet, they were purifying their blood, while in reality they were starving them into scrofula, are now generally recognized and avoided. (Stock's Life of Beddoes, p. 168.) Cafes may occur, when animal food may be injurious; and these may require at least a temporary suspension of it; but much more injury is done by a spare or poor diet, than by a reasonably full meal of plain nourishing food. Once a day cannot be too often for a meal in which meat should form a chief ingredient; and we need scarcely say, that its proper nourishing effects will be most experienced, where it is full-grown and not over-dressed. With plenty of air and exercise, warm clothing, and moderate temperature, there is little room to be apprehensive of injury from plenty of milk and meat. On the contrary, the best effects on the health and vigour of the system may be expected.

Professor Hufeland tells us, that those parents who accustom their children to drink water only, render them a service, the value and importance of which will be sensibly felt through life; and we fully agree with him. No beverage can be more wholesome, and we will even venture to say on the whole more nutritious, than good spring water. Those who have any acquaintance with animal and vegetable physiology, will not be surpris'd at the last part of this as-

sertion. But if we leave out of view its nutritious qualities, and consider it merely as a beverage free from the noxious qualities which forcibly present themselves to the minds of those who connect the future periods of life with the present, and which must induce them to shun the early employment of stimulating liquors of any kind, it is invaluable. It would amply repay the parent to give up the use of every stimulating beverage with his meals, for the sake of example to his children, and with a view to produce that habit of early temperance which cannot be too soon acquired. We have known the sips of wine and of ale, which many would think mere trifling indulgences, produce a propensity to the use of strong liquors, which has been attended, even at eight or nine years of age, with intoxication. And it shocks us to see parents so regardless of the bodily, as well as the moral health of their children, as to give them, when very young, (perhaps when three or four years of age, or even less,) a glass of unmixed wine, and even urge them to drink it. These same persons would be themselves averse to give their child half the wine glass of brandy, and yet the quantity of alcohol differs little in the two cases. Wine should be reserved for a medicine; and there may be times, even in childhood, in which, when diluted, it may thus be usefully employed. But in such cases, with a view to the future, no pains should be taken to render it palatable. The true way to prevent an early taste for stimulating liquors of any kind, is not to make them the subject of direct prohibition, but to keep children out of the way of them, and to accustom them to simple food and drink. Where the stomach of a child is not unnaturally excited, there will be little disposition to the use of fermented liquors. But if drinking them be made the subject of boasting, or even of expressions of lively pleasure, in the presence of children, our precautions may be easily rendered ineffectual. If a parent finds it necessary to introduce to his table visitors who will be thus careless of the moral welfare of the young about them, let his children take their meals in a separate room, till he has acquired such power over their minds as to prevent the mental poison from operating. Then it may be best for him to let them be exposed to it. They must eventually; and it is better that this should be done before the mind is likely to be so much influenced by it, as it would be at the more advanced periods of youth, when the antidote will not be at hand. But before that period, if wine is to be introduced at meals, and the bottle to be circulated freely afterwards, and made the subject of conversation, at least let not children be exposed to the impressions of the scene. Those who have known boys, under twelve or fourteen, habitually fond of intoxicating liquors, and taking various underhand methods to procure them, and even experiencing intoxication thus early,—who have known, too, a habit thus early begun, continued through all its stages, till life has been prematurely cut off by its poisonous effects, when the age of manhood had scarcely been reached,—will think no instance of self-denial or of prudential caution unreasonable, to prevent the possibility of such evils in their own families. Whether we consider it in its present and future beneficial effects on the bodily organs, (the digestive, biliary and nervous systems,) or in its great tendency to promote the culture of self-control as it respects the corporeal desires, the habit of temperance cannot be too early begun or too steadily pursued. Its physical, mental, and moral influence, its influence on health and happiness, entitle it to a high rank among the virtues of life. At first it will be a mere habit, formed only by parental care and influence; but as the child advances towards maturity of understanding, every

PHYSICAL EDUCATION.

judicious means should be employed, to give it the obvious and impressive functions of prudence and of religious duty (for such it has in every point of view that it can be considered); and these representations will be easily understood. The proper time for introducing them, is when any striking instances of the injurious effects of intemperance will render them impressive; and a few short *home* statements on the subject may then be of incalculable importance and efficacy.

With a view to such statements, we recommend to the judicious parent, (at least if not liable to excessive nervous excitement,) the study of Dr. Beddoes's eighth Essay, on the preservation of the physical power of enjoyment, including some remarks on food and digestion. They will find there "a description of the stomach and of its various states of distention and emptiness, with the corresponding sensations by which these states are accompanied. The progress of digestion is described in a manner strikingly clear and intelligible; and this is followed by an inquiry into the principal agents by which this process is impaired, and the digestive organs injured." The young often injure themselves for want of proper information on the subject of the bodily functions; and the parent may, from such sources, derive those which will enable them to render their children most essential service. Dr. B. appears to us sometimes to colour too highly; but the most important parts of his Hygeia we cannot doubt to be fully borne out by correct observation and experience. For the purposes of health, it appears that to take spirituous liquors, (whether in the form of wine or what are commonly called spirits,) after a meal, is of all periods the most improper. Proper food taken in proper quantity is exciting enough for the strong, and without caution is apt to be over-exciting for the weak. Fermented liquors act with peculiar severity on the tender constitutions of children. They stint their growth and impair their appetite. Numerous experiments prove this fact; and the indigent classes have, in some instances, availed themselves of a knowledge of it to still the cravings of that hunger which they had not the power of appeasing by a sufficient quantity of wholesome food. These facts ought to operate as a serious warning to the imprudent parent, who indulges his children in such a fatal gratification. They want no source of artificial exhilaration to beguile their time; however it may be sought, for those purposes, by those of more mature age, too little remembering that the pleasurable feelings of existence which arise from the products of vinous fermentation can only be momentary, and must be succeeded by a proportionate degree of depression and at last of gloom. (Stock's Life of Beddoes, p. 236, &c.) The following remark of Dr. Currie (which should have been introduced in Div. II.) deserves great attention: "Though *spirituous liquors* may fortify the body against the effects of heat, combined with moisture, and may perhaps support it for a short time under great fatigue, *they are, I believe, uniformly hurtful when taken under fevers and continued cold.*"

We are not apprehensive that we shall be considered as digressing on this point. That education, which, while it gives health and vigour in the early part of life, secures strict temperance and moderation in every kind of animal gratification, is rendering a most essential service to the mind and the body. The work of mental and moral culture may then be not only begun but pursued with steadiness and success; and that invaluable blessing, *mens sana in corpore sano*, will make the parent for ever recollecting with the most lively feelings of affectionate gratitude.

We must revert a little more to the subject of *water*. To have its proper effect it must be *pure*. Two precau-

tions, therefore, are to be attended to respecting the water which is constantly employed in food. The first is, that it be free from the oxyd (or rust) of lead; the other, that it do not contain too great a degree of earthy matter.

"Pure water has no action on lead; but it takes up a small proportion of the oxyd of that metal. When left in contact with water, with the access of atmospherical air, lead soon becomes oxydized and dissolved, especially if agitation be used. Hence the danger of leaden pipes and vessels for containing water which is intended to be drunk. Water appears also to act more readily on lead, when impregnated with the neutral salts that are occasionally present in spring water." (See Henry's Chemistry, vol. ii. p. 89.) Vats of lead have been used in some cider countries which have produced incalculable mischief. What is called the Devonshire colic is occasioned by this practice; and is identified, by its effects on the system, with the colic of the plumbers, the painters, and the white lead makers. "Lead in its metallic state, like all other metals, is probably inert; but it is so easily acted upon by the weakest acids and alkalies, that it cannot be taken without the most imminent danger." Johnstone on Poisons, p. 113. (See Parkes's Chemical Catechism.) The presence of any quantity of lead sufficient to produce injurious effects on the system, may be discovered by an addition of the sulphuret of ammonia or potash. (See Henry's Chemistry, vol. ii. p. 394, &c. in the chapter on the method of detecting poisons; where also will be found some valuable remarks on this and other connected topics.) The other point is, that the water in constant use shall not contain too large a proportion of earthy substances. (See Parkes, p. 243.) If the water is perceived to be particularly *hard* in washing with soap, or, if in boiling it, there is a great deposition of earthy matter on the internal surface of the vessel, it is, probably, likely to have injurious effects. Boiling it would deprive it, in a great measure, of its earthy mixture, but it will also deprive it of its briskness. Whether passing it through a filtering stone would take away the earthy substance we do not know; but we have known this process to give rain water (by its passing in small quantities through the air) that briskness which makes water a real luxury to those who habitually employ it. Probably the trouble, and certainly the expence, attending the procuring of good water from a spring, even at some distance, would, in general, be very much less than that arising from the employment of fermented liquors; and there would be the satisfaction attending the former, that it was certainly for the purposes of health.

It is necessary to say a few words on the subject of *tea*. We agree with Beddoes (see his third Essay) in almost every particular respecting it; and in this we are influenced by considerable experience and observation. We are not averse to the use of it in a moderate degree and of a moderate strength, especially among *young men*. The habit of afternoon tea-drinking has often a close connection with domestic dispositions, and tends to society at least less injurious than that of the bottle companion. It appears also to furnish, when thus limited, only a salutary refreshment after fatigue of body and mind. As long, however, as the stomach will bear a milk breakfast. (which might be diversified by using it in various forms,) so much the better. When tea is employed for breakfast, it should be weak, cool, (little, if at all, exceeding blood heat for instance,) with a large proportion of milk, and as much sugar as will render it palatable without sickening the stomach, and accompanied with plenty of toasted bread or thinly spread bread and butter, (in other words there should be as

little

PHYSICAL EDUCATION.

little tea as possible in the whole,) and we imagine that then no direct injury can result from it. The afternoon tea should be prepared in the same manner. If it is used in any form in which its stimulating effects are experienced it must be prejudicial to the young: and the tendency of the present employment of weak and well prepared tea, to lead to the injurious use of it hereafter, renders it desirable to keep clear of it as long as may be. Green tea possesses a power over the nervous system, which should completely prevent the general employment of it by any one. Like other strong stimulants it should be reserved for the period when it is requisite as a medicine, if there be such a one. Black tea is certainly less injurious: but even this (at least without such precautions as above stated) must affect the irritable habits of children too violently, to justify the use of it as a part of their daily diet. We recollect observing the effect of tea upon a boy of about nine or ten, (the same referred to under the head of *Bathing*,) having taken some strong green tea, with little milk and bread, and no sugar, he began about an hour and a half after to manifest excessive depression, accompanied with weeping, for a considerable time. He was, in some measure, restored to his usual tone by a comfortable supper; it is probable that as the stimulus had thus exhibited its genuine effects afterwards it had done so in the first instance by producing a temporary exhilaration.

One point connected with this head we do not wish to omit, because we deem it really important, though we doubt whether even the authority of Locke will appear broad enough to shelter us completely. The philosopher devotes five sections to the subject in his *Thoughts on Education*; we shall take the abridgment of them, which we find in the *Parent's Friend*, vol. i. p. 5.—“One thing more there is which has a great influence upon the health, which is costiveness. The contrary extreme is always attended to, and can sooner be remedied; but costiveness is harder to be dealt with by physic, as purging medicines rather increase the evil. I believe the best remedy is, for people always to solicit nature immediately after their first eating of a morning; and by this constant application they might bring it into a habit, whether they are at first called or not: and they should never let any human affairs prevent this necessary attention to their health. Children should be early accustomed to this, and should not be let go to play till they have been effectually at stool, as there is reason to suppose that many children neglect the gentle calls of nature, when they are very intent on their play.”

VII. *Muscular Exercise*.—Healthy children will exercise themselves sufficiently if they are allowed: and they should be allowed, during the period when the body is the first concern, almost as much as they please; and, after that period, as much as is necessary for the vigour of the body, if it were only with a view to the vigour of the mind. They should be encouraged to such bodily exertions as will call into play the muscular system generally; seldom excessive or violent, but active and vigorous; proportioned in fact to the degree of strength actually possessed; and so contrived that, while it benefits the present health, and suits and excites the lively spirits of youth, it may also lay in no store of injury for the future. The last principle excludes those violent sports, which, before unusual vigour has been acquired, can scarcely fail to over-excite the system, and produce lasting injury to it. So far, indeed, from wishing to see boys and girls shrinking from exertion, or the apprehension of pain, we would have their education so conducted, that they shall be at all times ready to en-

gage in any exercise which is not beyond their strength, and ready to undergo any pain that will have only an *immediate* and *temporary* effect. Those which *really* and *considerably* endanger the limbs, or the senses, the health, or even the lives, are what we term dangerous sports; and the danger should be early and repeatedly pointed out to children, and such sports prohibited: but all that are active, that exercise the bodily or the mental vigour and ingenuity, should be encouraged, and sometimes assisted by advice, or by the parent's taking a leading share in them. We say sometimes, because as much as possible should be left for children themselves to do. Parents should sometimes lead, but only in order to teach them to go alone: and except when this is the object, the parent will be of most service, by taking only an ordinary play-fellow's share in his children's amusements.

When children are healthy, and have been accustomed to a few simple sources of amusement, to such playthings as they can use freely, and as will call their minds into exercise, they will invent for themselves; and all that is necessary is, to give them a dry airy room in doors, and a dry airy spot out of doors, where they can play freely and actively, and to furnish them with a few implements for amusement suited to their age, such as the recollections of an active childhood will readily suggest. The rest they will generally do for themselves. A little indirect aid may sometimes be of service to give a right direction to the stimulus of their own minds; but the less direct interference the better.

We hear a great deal of boys loving play too well; and there are, doubtless, instances in which a real love of play has been attended with little or no marks of mental activity; but we see every reason to suppose, that if a boy play *well*, (with activity, spirit, and ingenuity,) it only wants proper management to make him work well. Of such a one, at least, we should ourselves never despair. If children are indolent at play, it must be from a want of sufficient animal health and spirits, and proper means should be employed to restore them to that state. A child in thoroughly good health, will, at times, be as playful, and full of antics, as a young kitten; and without indulging that boisterous rudeness, which is inconsistent with domestic comfort, and with the necessary degrees of order and propriety, and even with the health and comfort of the children themselves, every possible indulgence should be given to their lively spirits, and to their cheerful noises.

At the period when the habit of *hardy* application is to be begun, we do not wish to see work treated as play: and, on the other hand, play should never be made work. Children may often be *led* to do, that which they have no direct inclination to begin; and a little skill in bringing about this beginning is often of real advantage. But exercise will be of the greatest use, (it will most call into exertion the physical powers, and contribute most to the health,) when it is indulged involuntarily and with spirit. Those exercises which are *expressly taught* with a view to form the limbs, and give young persons a proper command over them, must, we apprehend, be excepted (we refer to dancing, drilling, fencing, &c.); and it may sometimes be necessary, for a time, to make them compulsory; but by proper care and perseverance, they will become pleasant enough. We think highly of all these exercises. Dancing is often abused; often made the source of vanity, and sometimes even of sensuality. Exhibition-balls for children and youth we deprecate; and are satisfied that the evils attending them are many and great. The private cheerful dance, where con-

ducted

PHYSICAL EDUCATION.

ducted with propriety, and not carried to excess, (by overheating or over-exerting the system, or by encroaching upon the part of the night which health requires to be spent in bed, an hour or two before midnight,) we think a salutary amusement, good for the body and for the mind. If it have the effect the next day of producing languor and inaptitude for the common employments of life, then it has been carried to excess.

It has been proposed to make *gymnastics* a part of the regular business of education. A tame spiritless exertion of the body is worth little. Some good may be done by it; but what should be the object of the parent, is voluntary active exercise, in which the whole soul is for the time engaged. The formal walk, even in the fields or on the seashore, however much it may please, by contrast from sedentary amusement, and which it will do only in proportion as that amusement has been kept within its due limits, cannot have nearly the same beneficial influence on the body, or on the mind, as the lively sportive exercise which healthy children will take of themselves. A troop of boys or girls, turned into a field to find amusement for themselves, and left at full liberty, except that of transgressing the bounds which mental or bodily health prescribes, will do for themselves, that which no one else can do for them; they will be gaining life and vigour, muscular activity, and, what often is intimately connected with it, mental activity. Still we are disposed to allow, that regular attention to gymnastics should make a part of the system of education; but then the regularity of the management of it should be kept out of sight as much as possible. The parent or the tutor may plan and lead to the execution, but the execution, and, as much as possible, the plan, should originate in, or at least excite the ingenuity, the dexterity, the exertions, &c. of the child or youth. If children are not early allowed full employment for their bodies they may require to be taught to play; but the art employed to teach them should not be brought into view. In fact children teach themselves best; and the inspecting, controlling, directing power of the older friend should seldom be the direct object of observation. He may notice in silence, and give hints from what he has seen, which will do every thing that is necessary. Constraint destroys the very life and soul of play. From what we have seen of an octavo volume, entitled "*Gymnastics for Youth*," translated from the German, we think that the parent, (under which general appellation we usually include the tutor or parental friend,) may derive some useful hints to aid him in the great and important object of bringing the muscular system into full vigour and activity. We must by no means omit the valuable chapters on Toys and Machines, in Edgeworth's *Practical Education*, which every reader of this article probably has access to. And from extracts which we have seen from Parkinson's *Dangerous Sports*, we expect that valuable cautions may be derived from it, deserving the attention of the judicious parent.

We would not have the prohibition of dangerous sports carried too far. Those whose consequences may be, and especially those whose consequences will probably be, fatal, or the injury irremediable, should be absolutely prohibited, and the disposition to avoid them produced by considerations of prudence and benevolence. Forced exertions beyond the strength, blows on the head, stomach, &c. injury in the eyes from any cause,—these, and all others coming under the above description, should be the subject of frequent caution. But in real life occasions continually occur, in which pain must be borne, or in which some degree of risk must be run; and that education must be radically defective, which does not sow the seeds of fortitude and presence of mind.

Nothing will teach these qualities but exposure to pain and some degree of danger. We do not mean a voluntary direct exposure; but we would check that excessive caution on the part of the parent, which shuns present suffering at the expense of future strength of mind. The benumbing influence of fear injures beyond calculation; and though we have no wish to see foolhardiness, which is bold because it is unacquainted with the real extent of the dangers it runs into, we do always rejoice to see in a lad firm endurance of pain, and active boldness, under the guidance of some little prudence and ingenuity in extricating himself from risk, without paying more attention to the danger than is necessary to escape from it. Cowardice is so often, we might say so constantly, the source of meanness, and all its accompanying vices, and (even where the moral education has checked these) is so often a bar to valuable exertions for the good of others, that every indication of it should lead to proper methods to eradicate it. Some may suppose that all that is necessary is to give strength and health. So far from fortitude being a necessary attendant upon these, we have seen reason to consider it as a more constant companion of activity of mind, united with less robustness of body. Activity is the grand point; this will lead a boy into risks, (we do not mean of fatal accidents, but of such as for the time may be painful,) and the same activity will often suggest expedients to escape from them; and the more this is done in early life, the more self-command and presence of mind will be practicable, when necessarily exposed to great and imminent danger. Presence of mind, as Miss Edgeworth has well observed, is, in reality, absence of mind, as far as the danger is concerned: on that it does not dwell, but upon the expedients of escaping it. And it must require uncommon mental culture in the later period of life to acquire this invaluable quality, where fear has been the habit of the earlier.

The little accidents of childhood and youth should not receive too much sympathy. All that is necessary for their relief should be done, at least in the earliest stages of education; but the little mind should be excited to bear its pain, by pleasantry, or even raillery, by appeal to shame, by turning the attention from it, in short by any and by various methods, those being selected which experience has shewn to be most effectual for the individual. After the first period of childhood, their accidents should receive very little direct attention; the parent will observe, but the observation need not be made to excite their notice. He should be ready to step in where necessary, but in common cases leave them to act for themselves. Indeed this is one grand object in education, to enable the individual to act for himself, when the great business of life depends upon his own wisdom and exertions.

When the dread of pain (even where the mind is unsupported by sympathy, or not stimulated by the dread of shame) is in a considerable degree subdued, or made inactive, (in other words, when fortitude has been acquired,) there is only one thing more requisite for effectual presence of mind, and that is a knowledge of the best methods of escaping danger, a readiness of invention, and the adoption of means to ends. These are more intimately connected with the culture of the imagination and the understanding. To produce them, the young should often be led to consider what is best to be done in accidents of different kinds. "What would you do if your clothes were on fire?" we would ask a girl old enough to understand and to act. "What would you do if your brother fell into the water, or fell down and broke his arm?" are questions which would lead to useful conversations with a boy. When occurrences

PHYSICAL EDUCATION.

of this nature are mentioned, the mind of an intelligent youth may be set to consider what should have been done, and then compare it with what was done. Where this turn is given to the inventive powers, highly useful results might be expected, not only when in actual danger, but in providing against the accidents of human life for others. Newton Bosworth's little book, entitled *Accidents of Human Life*, will furnish some useful hints; and it would be well to keep a common-place book for this express object, which might be stored with facts of actual occurrence, and with suggestions as to probable cases in future. An acquaintance with the structure and functions of the body, with chemistry, and with mechanical philosophy, cannot fail to be of great use for this object, and attention to them with this object in view, will be of service in others. Our readers will find some hints which may be of service in *Intellectual Education*, Div. V; and still more towards the close of Miss Edgeworth's chapter on Attention. The excellent little dialogue in *Evenings at Home*, called *Presence of Mind*, well deserves the perusal of parents as well as children.

To any one who fairly considers the way in which the bodily and mental faculties are developed, it will appear abundantly clear, that exercise is as much required for the one as for the other; and as the mental progress so much depends upon the health of the body, even if that be to be regarded as the primary object, this must on no account be neglected. "Exercise is necessary for health, bodily and mental," should be the fundamental maxim of every system of education private or public. It is a law of our natures, against which no one can offend with impunity; and such arrangements should be adopted in every school, and in every domestic plan, that it may be fully and effectually obeyed. Sedentary employments should be frequently relieved by active muscular exertion. It is a bad thing for the mind to be kept on the stretch too long; and, therefore, sedentary amusements are often necessary; but sedentary amusements should only be resorted to where active sports cannot be had. Bodily activity is almost an essential requisite for mental activity, and indisputably for the full enjoyment of health. If from any circumstance the school hours exceed two or at most three hours at one time, let a break be made at some convenient place for "a good batch of play." Little will be lost by it for the time; much will be gained for the future. Exercise out of doors, where dry good air can be had, is, in every point, greatly to be preferred; but where the rain and chills of our climate will not permit, still let it be had within.

When children have been sitting so long, that they feel indisposed to bodily exertion, there is no doubt they have fat too long.—"Like every other organ, the palate and the stomach, when left inactive and unexercised, lose their original faculties. Repeated fasting is fatal both to appetite and to digestion. Sedentary occupations," we would say too long continued, and disproportioned to the age and degree of muscular maturity, "gradually destroy the desire, and impair the power, to exert the muscles, more particularly while they are forming."—"To debar children from giving loose to these inclinations, by indulging which, they knit their sinews, swell their muscles, and harden the whole against the vicissitudes of air, is a kind of severity neither indifferent to them or to those about them, for the present or for the time to come."

It really appears somewhat unnecessary to dwell upon this subject as we have done; and yet it is difficult to meet with any plan of education into which it enters as it ought. In making the above quotations from Beddoes (*Ed. iii.*)

we observe, that in his plan for a girl's school, which we think in many points very judicious, (though clearly formed more with a view to *weakly* children, than could in general be desirable for girls and still less for boys,) he lays down the following precept: "under twelve years of age it should be an invariable rule, that the hours of application should never exceed those of amusement and exercise." The principle is a good one; and it should not much be departed from, till the period when application becomes voluntary and pleasant; and then some portion of the hours for *amusement*, we do not include those of *active exercise*, may be added to those of application. We are inclined to think that, in general, for boys between ten or eleven and fourteen, nine hours sleep, eight hours work, and seven for meals, exercise, and amusement, is a good division. Those, who see reason to adopt our views in *Intellectual Education*, especially under the heads of *Attention* and *Memory*, will be of opinion, that Dr. Beddoes' plan is in these points radically defective. It affords useful hints, but it cannot be followed, we apprehend, and at the same time mental *vigour* be obtained.

But while we say this, we must add, that we deprecate, as he does, excessive mental exertion in children. The physical system must be the first object. If the order of nature be reversed, the mind will eventually suffer for it, as well as the body. It would often be easy for the skilful parent to make a child a prodigy; but the judicious parent never will attempt it. Premature and luxuriant growth of mind will seldom, if ever, be found to spring from a vigorous root. It will be viewed by those, who know the laws of human nature, as a disease; and such it will generally prove, even in the estimation of the mere superficial observer. We do not doubt, that many have sunk into an early grave, through the unnaturally rapid development of their faculties, and the excessive excitement of mental and physical sensibility, which is usually the cause or effect of it; and still more have had the progress of their bodily health and strength impaired; their minds have sunk into a state of stagnant listlessness; and the promise of early genius has been completely disappointed, and followed by a train of physical and mental and moral evils, which should serve as a beacon to the vain or the unwary.

Though this article is expanding beyond our wishes, we cannot forbear presenting our readers with another extract from Search. The Light of Nature may not be accessible to many; and this passage is truly important, and deserves to be carefully weighed by every parent.—"Nor is it enough to restrain sleep within due bounds, if the waking hours be suffered to dream away in a torpid indolence not much different from sleep. It is of great service, even to the health, to cultivate a spirit of activity, continually exerting itself in some exercise either of body or mind. The former is more necessary for the animal machine, and for that reason deserves to be particularly regarded for such as are destined to follow some sedentary profession, that they may be inured by early custom never to sit still with their hands before them in the intervals of business, but to move briskly in their common actions, and daily to practise such recreations as may keep the circulation to its proper flow, and prevent ill humours from gathering in the blood.

"Yet an activity of mind, too, is not useless to the body; there being such an intimate connection between the grosser and finer organisations, that irregularities in the one, will not fail to produce their like in the other. There are some who love to sit in a corner, building castles in the air, musing upon improbabilities soothing to their fancy, and wishes of what can never happen, or perhaps upon something

PHYSICAL EDUCATION.

something that has vexed them, or the imaginary dread of mischiefs never likely to befall them; though this may seem an intenseness of thought when the mind is rather too busy than too remis, it is in reality not an activity, but passiveness bound down to an object rising mechanically in the imagination. Tempers of this cast have a perpetual listlessness and dilatoriness, they apply to nothing readily, they do nothing currently, but want to put off every thing another minute, even their meals, their diversions, and their beloved nightly repose. Such stagnation of thought, become habitual, must inevitably introduce a like stagnation of the vital juices, fret and waste the spirits, generate fearfulness and melancholy, and impair the health more than will be easily imagined.

"This mischief then deserves an early attention to obviate, the more because difficult to be discovered in its beginnings; for we cannot penetrate into the thoughts to see what passes there: but before grown inveterate, it will shew itself in the actions, or rather in the inertness of disposition; and then no time should be lost to cure it, nor any means omitted that can be devised to teach children to find an issue for their thoughts by running them in current trains, and to take pleasure in making good dispatch of every thing, as well in their tasks as their amusements.

"Nevertheless it must not be forgotten, that there is a contrary extreme, which urges to make more haste than good speed; a continual hurry and agitation, never satisfied but when in motion; an impatience to do things before the proper time, and eagerness to dispatch them at once by a violent exertion; an over-solicitude for the success of measures, and a vexation upon any rub happening to fall in their way. This temper likewise is unfavourable to the health; for mischief will ensue upon precipitating the circulation of blood and animal spirits, as well as upon retarding it. A calm and steady alertness, flowing in one uniform tenour, always brisk and lively, never anxious nor trepidating, is the desirable point to be pursued: therefore, we must so labour to cure one evil, as not to incur another; and keep an eye upon Scylla, while we endeavour to steer clear of Charybdis. I know it is a difficult matter, perhaps impossible, to hit exactly the golden mean; but we shall come the nearer, by being apprised of dangers on either hand: though I think the former is the greater, the more frequently fallen into, and harder to be cured. The best that can be done must be by diligence in watching the approaches of either, and applying the proper remedy as soon as they are perceived."

In what we have said, we wish to be understood as referring, unless otherwise expressed, to girls as well as to boys. We are fully satisfied that there is a constitutional difference in the sexes, which is perceptible even from infancy; and that the parent, who should train up her daughters to all the most robust exercises of boys, would find that she had carried the matter too far. But we are also satisfied, that this constitutional difference is unnecessarily and most injuriously carried beyond all the bounds of nature, in the common modes of educating girls. We recommend to mothers, especially, some remarks on this subject in Reflections on the present Condition of the Female Sex, by Priscilla Wakefield; a writer who has contributed well to store the children's library with works containing really useful information. "How often," she says, (we quote from Parent's Friend,) "has our anxiety for the delicacy of the complexion, or the apprehension of her becoming a romp, restrained a girl from the indulgence of enjoying either air or exercise, in a sufficient degree, to secure her from that feeble, sickly, languid state, which frequently

renders her not only capricious, but helpless through the whole course of her life. There is no reason for maintaining any sexual distinctions in the bodily exercise of children. If it is right to give both sexes all the corporeal advantages which nature has given to enjoy, let them both partake of the same rational means of obtaining a flow of health and animal spirits, to enable them to perform the functions of life."—"Employment should be contrived, on purpose to induce them to pass a large portion of their time in the air; nor should they ever be permitted to sit within long at a time. A mere walk scarcely supplies sufficient exercise to produce a quick circulation; something, therefore, more active should be adopted. Running races, trundling a hoop, skipping with a rope, battledore and shuttlecock, ball, jumping, dumb bells, swinging, and many other amusements of the like nature, are suitable for the purpose, and may with equal propriety be practised by both sexes, being by no means incompatible with delicacy of person and manners. Let it never be forgotten, that true delicacy consists in a purity of sentiment, and is as much superior to its substitute, external manners, as a real gem to one that is artificial."

VIII. *Exercise of the Senses.*—It is certainly possible to have eyes, and yet not see; and to have ears, and yet not hear. This, however, is in general more owing to the sluggishness or inattention of the mind, than to the imperfection of the external organs of sense. Impressions on the organs of sense, which, if the attention of the mind were actively directed to them, would convey clear, vigorous, and well-defined sensations, may either excite a mere partial or fleeting notice, or pass away without any sensation whatever. See *Mental Philosophy*, Div. I.; and in connection with other topics of this division, the reader will probably find some advantage in consulting Div. II. also.

In *Intellectual Education* we have endeavoured to mark the distinction, which is too seldom observed, between *sensations* and *perceptions*; and we shall not enter upon the subject again. The reader will find the first four divisions of that article bear closely upon what may well be termed the mental processes of perception, and we beg leave to refer him to them for this purpose. Dr. Reid, in his *Essays on the Intellectual Powers*, has a distinct chapter on the improvement of the senses (Essay II. chap. 21.); but from the views which that philosopher took of the nature of perception, it might be expected, and it is accordingly the fact, that he says but little on the improvement of the *senses* properly so called: it is principally on the improvement of the perceptive power. The philosophical reader may, however, find it worth while to consult that chapter; and the judicious, but inexperienced mother will also derive much useful information from the second and third letters in Miss Hamilton's second volume.

That the perceptive power is susceptible of very great improvement, by proper exercise and culture, there can be no doubt; but some may doubt whether this is the case with respect to the bodily organs of sensation. When it is considered, however, that improvement, as the consequence of due exercise, is the grand law of our physical and intellectual powers, it might be inferred that the external organs are, by the same means, susceptible of improvement, in furnishing correct and vivid sensations. And when it is considered that even well-formed healthy infants indicate little sensibility of sight and hearing for many days; that there are manifest and great differences in the animal tribe, in the powers of sensation; that even where there is the power of vigorous attention, children greatly differ in the correctness and vividness of their sensations; that those who are accu-
tomed

PHYSICAL EDUCATION.

taught to observe objects of a certain class, not only have much more ready and accurate perceptions, but even can at once discern, where sensation only is concerned, what very close attention will scarcely enable another to see; that those who are deprived of one of the three organs of intellectual sensation, acquire a peculiar susceptibility, not only of perception, but of sensation from the others; and that at the period of natural decay, and even earlier, there is a great diminution of the power of sensation; it appears to us scarcely to be doubted, that the bodily organs of sensation are susceptible of great variation and improvement in the same individual.

Even if this should still be regarded as matter of theory, it is obvious that no effort in endeavouring to improve the senses can be lost: for by the same means we shall be effectually improving the faculty of perception. And, on the other hand, whatever means are taken to exercise the perceptive power, these will, upon the above principle, cultivate also the organs of sensation. The exercise of the bodily organs, and accurate attention to the impressions upon them, are, in fact, the only direct means by which this last object can be effected. The indirect means are of indispensable importance, and will do much towards rendering the direct means of real efficacy: we refer to those means by which the bodily health, vigour, and activity, are to be obtained. The exercise of bodily vigour, and especially of bodily activity, not only has the effect of strengthening the nervous system generally, and of giving it a *healthy* sensibility, but it furnishes constant exercise for the organs of sensation. The useful playthings of childhood and youth, and their employment out of doors, are continually calling these organs into activity; and that agility in muscular movements, with which health and activity are so often attended among the young, and which contributes so much to give bodily dexterity, is peculiarly serviceable in calling into play the power of sensation also. Dexterity does of course imply the quick and vigorous sensation, and accurate attention to it, and the ready association with it of the appropriate muscular movement; and where it is exercised, there the organs of sensation must also be exercised. In short, wherever and however the attention is directed to the objects of perception, whether in the way of simple observation, or of comparison and discrimination, the corresponding organ of sensation is undergoing a proper culture.

Hence a great deal may safely be left to the mere influence of external objects, provided the attention is pretty steadily and frequently led, directly or indirectly, to the perceptions. A child who observes much, must acquire quickness of perception; a child who observes accurately, must acquire accuracy of perception, and consequently must acquire quickness and accuracy of sensation. But there are few cases in a judicious education, in which all will be left to this indirect exercise. During the plays and employments of childhood and youth, various means may be devised of calling the senses into activity, and directing the attention to them. In the book which we before referred to, "*Gymnastics for Youth*," there are some useful suggestions respecting the method of artificially exercising the senses, which we think may be serviceable to some of our readers, and which we shall give in the form in which we find them in the "*Parent's Friend*."

"Besides the natural exercise of the senses, I think it might be possible, by artificial means, to increase the power of each sense, in the same manner as hundreds of deaf and blind persons, who supply, to an astonishing degree, the loss of one sense by the zealous cultivation of another. Accordingly, in exercises of this kind, sometimes the eyes

should be covered, sometimes the ears prevented as much as possible from hearing, sometimes the rest of the senses kept as free as may be from impressions. When children have acquired considerable readiness by the natural exercise of the senses, in their eighth or tenth year perhaps, I consider it as a very pleasing and useful occupation to exercise them artificially in the following manner." Though the author speaks of the age of seven or nine as a proper time for the artificial exercise of the senses, it is obvious that it may be begun with advantage at a much earlier period. In fact, it can scarcely be begun too early. But, throughout, it should be conducted as little as possible in the way of a formal business. The exercise of the muscles, and the exercise of the senses, should be made as interesting as possible, and seldom employed except in the way of amusement.

(1) "*Exercise of the Touch*.—The much greater promptitude of the sight and hearing, evidently leads us to neglect the sense of feeling; whence I am induced to think, that this deserves our greatest attention. The eyes are to be previously covered, and then let the person so blindfolded discover persons by feeling their faces or hands; distinguish coins; tell what a person writes in the palm of the hand with a pencil or point of a skewer; distinguish the leaves of all kinds of trees and plants with which he is acquainted; estimate the degree of heat, air, and water according to the thermometer; distinguish plates of polished metal, of similar figures, by their specific heat; estimate the weight of various substances in pounds, ounces, and the smaller weights; tell all kinds of wood, and the different productions of the loom; estimate the number of leaves in a book and tell the pages; among a number of leaves of the same kind of paper, separate the blank, written, and printed; write; estimate the length of various sticks in feet and inches, the superficies of a table, the solid contents of substances of regular figures, and the capacities of different vessels; mould easy figures, mathematical for example, in clay or wax, paying attention to the size as well as the form; make pens, and cut out various objects; distinguish all kinds of substances put into his hand, as chalk, sealing-wax, &c.: let him endeavour to feel impressions in relieve, as upon large coins.

(2) "*Exercise of the Sight*.—Let him estimate every relation of magnitude as it exists in nature; length, breadth, height, depth, superficies, solidity, and distance: both in the great, as yards, furlongs, miles; and in smaller dimensions, as feet, inches, lines. The conjecture should always be compared with actual measurement. This will at the same time afford a pleasing mode of practically acquiring the art of mensuration. On sultry days, for which more violent gymnastic exercises are not so well adapted, I have often had recourse to these, and found that young persons very soon acquire a considerable readiness in them. It is above all things necessary to imprint as deeply as possible on their minds accurate ideas of the different measures. When this is done, they will soon learn the art of applying them in all directions, and thus measure with the eye. Let him draw all kinds of mathematical figures without compasses or ruler, divide lines into a given number of parts, cut measures of feet, inches, and lines upon sticks, copy mathematical figures in perspective from models, draw schemes for them, cut them in paper, and put them together. All this must afterwards be examined by mathematical instruments, and the errors corrected. Let him take for a pattern a picture, on which are many different shades of colour; compound every shade in it from the seven primary colours, and lay them all down upon paper; or let him merely declare of what colours each shade is composed. Let him estimate the weights of

PHYSICAL EDUCATION.

various bodies by looking at them. Let him stop his ears with his fingers, and hold a conversation by observing the motion of the lips.

(3) "*Exercise of the Hearing.*—The youthful company, in which the fewer there are the less noise is to be apprehended, being all blindfolded, their master will do various things, and they must tell what he is about; in other words, he will occasion some noise in different ways, and they must explain whence the noise arises. This admits of great variety. All common actions, such as walking, writing, making pens, and the like, are easily discovered; accordingly the master will proceed to such as are more unusual, for instance stepping upon a chair, or sitting down on the ground. When these are discovered, with tolerable facility he will go farther. He will bid them guess the figure, size, and substance of things by the ear. For example, whence proceeds that sound? from a glass, a basin, a bell, a piece of iron, steel, copper, silver, wood, the table, or the bureau? Of what size, and of what shape it is?

(4) "*Exercise of the Smell and Taste.*—A person blindfolded may distinguish flowers, various articles of food, many metals, leaves of trees, fresh, and in many cases dry pieces of wood, and several other substances, by the smell alone, without touching them, and most of them by the taste."

IX. *Sensibility.*—The sense of touch deserves to be regarded as distinct from the general sense of *feeling*, which, with the exception of those of sight, hearing, smelling, and taste, refers to every sensation experienced in any part of the body, either from internal or external impressions, and upon which principally the physical sensibility depends. We do not mean that when the nervous sensibility in general is great, there will often be found deficiency in the organs of sight, hearing, &c.; but that what is well termed *sensibility*, both physical and mental, depends principally upon the organs of feeling. Now the great object with respect to these is, not to rouse them to irritability, by direct or excessive excitement; or to produce that irritability by methods which cannot be unattended with essential injury to the bodily health, such as over-exertion of mind, want of air and exercise, excessive warmth, &c.; but, on the contrary, to bring the system into, and to preserve it in, that state in which the simple natural pleasures of feeling (the pleasures of health, of activity, &c.) are enjoyed, and in which there shall be no unnatural tendency to the pains of this sense. How great a share these have in producing the mental pains, may be understood by the remarks on this sense in *Mental Philosophy*, Div. II. And on the subject of this section, we wish to refer the reader to *Moral Education* III. 10. 11. 12.

The general law of the *sensible* pleasures and pains is, that by simple repetition they lose their vividness, and their effect upon the mind; and the same is the case with the mere passive *mental* feelings. Yet it is of great importance to be borne in mind, in early education, and in the individual's self-culture, that where any part of the system of feeling is unduly called into exercise, it increases the irritability of the whole; that the physical powerfully acts upon the mental sensibility, and this in turn upon the physical sensibility; that whatever increases the pleasures of sensation beyond their natural state, must also increase the susceptibility of the sensible pains; and that the influence of these upon the happiness, (where they arise from, or are accompanied by, an excessive irritability of the nervous system,) far exceeds that of the sensible pleasures arising from such excessive excitement of body or of mind.

One grand object of the early period of education should

be, to bring the physical system into its due state of health, vigour, and activity. If this be successfully pursued, all is done which is requisite for the proper regulation of the physical sensibility. All the means which we have heretofore suggested, if employed judiciously and steadily, have the direct tendency to give the nervous system its due tone; to make sensations have their proper influence in the intellectual system, and to keep them from having too great influence in the system of internal feeling. On the one hand, these means will tend to correct that extreme nervous irritability which might indeed be employed successfully to produce a rapid and premature development of the faculties and affections, but which cannot be called much into play without sapping the foundation of the health of body and of mind; and, on the other, they will supply the best physical prevention of the formation of that morbid sensibility which so continually fixes the mind upon its own feelings, which implants selfishness in its most refined, perhaps, but most ruinous forms; and which seeks for gratification, or at least relief, in that unnatural excitement which only feeds the corroding irritability of the system, and must by degrees destroy the capacity of enjoyment, and plunge in perhaps irretrievable calamities. The early and external means for the cure or prevention of excessive sensibility, must however be supported by internal aids. A disposition to active exertion,—a love of order and regularity, (which we deem of incalculable importance,)—a taste for mental employment not exciting to the mind, but engaging its attention, and calling into play and strengthening its various powers; in their due measure and degrees,—a disposition which will turn the sensibility which exists into the channel of benevolence and piety,—fortitude with respect to personal pains,—patience with respect to personal privations,—and the habit of self-control early checking or preventing that wild hankering after mere pleasure which never yet did any thing but harm, afterwards called into exercise, and supported by reason and religion, to prevent every sensual gratification which prudence and duty forbid,—these cannot fail of being attended with the most beneficial effects on the health and happiness: they will conduct the youth to the maturity and vigour of his bodily powers, and of intellect and affection: they will enable him and prompt him to act well his part in life with usefulness to others, and with honour and comfort to himself: and we need not say that they will serve as a noble foundation for religious excellence.

The following passage contains a picture of "that morbid sensibility which renders existence in many instances an almost uninterrupted series of painful sensations," which should make those concerned in education do what they can to prevent such dreadful evils. It is true it is an extreme case; but those who have had occasion to observe the appearances of morbid sensibility in less extreme and too common states, will perceive, that, in their degree, the features of the picture belong also to them. "That the dropping of a hair-pin on the floor should make a person start from her seat, and fix her in a preternatural posture, by occasioning preternatural fixed contractions of the muscles, or agitate her by contractions and relaxations equally preternatural, till she sinks into insensibility, from which she awakes into vehement delirium, is hardly credible to those who are conversant only with the healthy, and the sorts of sickness to which the robust are subject. On comparing an individual liable to these sad varieties of being, to the engineer who stands unmoved amid the thunder of a battery; to the seaman who maintains his footing upon the deck, or ropes of his vessel reeling under the shock of the elements; or to the

PHYSICAL EDUCATION.

The Indian who exhibits the signs, and probably feels the throb, of intense delight, while the flames are preying upon his flesh; how astonishing do we find the range in human susceptibility to the effect of the powers by which we are surrounded! how important is it to consider the causes of the difference, if on the one hand we should have as much reason to suspect that resistance to pain may be united in the highest degree to capability of pleasure, as we have, on the other, to be persuaded that those who have become in so high a degree sensitive, are nearly lost to all but painful emotions; and that if their organs are like wax in being impressed by external impulses, they too often resemble adamant in retaining what impressions they may receive." Beddoes, as quoted by Stock, p. 252.

Infancy, melancholy, epilepsy, palsy, and a whole train of evils, are the attendants upon an undue, excessive, and long continued excitement of the nervous sensibility; and it should be one leading object of education, among females in particular, so to direct their employments, their amusements, their diet and temperature, their waking and their sleeping hours, that their constitution may be hardened, their bodies and minds invigorated, and the best chance given them for meeting the unavoidable evils of life, so that these may promote their moral improvement, without inflicting upon them unnecessary sufferings, or destroying their powers of usefulness. With this view, it may be laid down as a maxim in education, that whatever strongly excites the sensibility, without connecting it with active exertion, whatever, in short, increases the disposition to passive pleasure, is, and must be, injurious,—injurious to the health of the mind, and alike injurious to the health of the body. To make such sickly sensibility the subject of approbation is folly in the extreme.

How the sensibility, in its natural state, should be turned into the channel of benevolence, we have endeavoured to shew in *MORAL Education*; and the reader will find some judicious observations on the same topic in Miss More's *Strictures*. With respect to girls, what in general is most wanting is, to check their sensibility, or at least to give it its proper direction. With respect to boys, it may sometimes be necessary to excite their *mental* sensibility; but in general, where proper pains have been taken early in life, the benevolent affections will have sufficient vividness and vigour; and at any rate they should never be enlivened by stimulating the sensibility of the nervous system. A boy should, if possible, be kept from the feeling that he has nerves; if we find his affections and intellect strong and vigorous, that is all we can wish for.

X. *Purity*.—The work of education has, indeed, an extensive scope; and no department of it can be neglected without injury to the rest. Physical education is of the first importance in the earliest periods; but if it be even then made an exclusive object, the consequences must be highly injurious. An unrestrained mind in a vigorous body, as we have already observed, will be the most likely to sink into the lowest moral depravity, and eventually to destroy, by this means, the object to which so much care and exertion had been devoted. Without attaching any importance to the number *seven*, as pretending to set limits, which, in a great variety of instances, must be merely arbitrary, the interval between birth and manhood may be conveniently divided into three periods, of seven years in each. During the first (unless the imagination of a child has been allowed to gain an excessive preponderance, and the elements of desire have risen to an enormous height) there must be uncommon impurity in the language or actions of those around

them, if the conceptions or desires have, in any degree, a sexual complexion. But during the second, (more especially if children associate much with others *older* than themselves, who are not under the restraints either of delicacy or decency,) it is an unhappy fact, that long before there can, in the order of nature, be any proper sexual desires, there is not unfrequently a degree of indecency in language and manners, against which the parent, who is anxious for the moral welfare of his children, should most sedulously guard. We have known this to be the case, even where boys have been brought up at home, having been allowed, however, to mix with those who themselves had little moral control; and we see reason to think it particularly the case at those schools where boys of the second period are allowed a free intercourse with those of the third. Hence we admire the plan which appears to be gaining ground, of schools for boys from six to twelve. If they are thoroughly well regulated, under the superintendance of able persons, and they give especial care to the prevention of impurity in language, &c., the most beneficial ends may be answered. Perhaps even a progress in the languages might, upon an average, be made in such seminaries as satisfactory as at schools upon the usual plan; the rudiments of other valuable branches of knowledge would be gained more effectually; and, above all, the moral culture of the mind might be carried on with much greater success. As far as our experience goes, it is more difficult to restrain the impure language of young boys, whose minds have received an early taint, than of older ones, unless, indeed, the disease has taken a deep and alarming root. In the former case it is extremely difficult to instil that sense of impropriety, which, where there is any moral feeling, may be produced in this connection, soon after the age of puberty. Some may think that great care on this subject is a refinement of squeamish delicacy, and not a necessary precaution of moral purity; we are however satisfied that such will not be the opinion of those who have studied the laws of the human mind, or who have observed the power of words over the conceptions of the imagination and the excitement and the direction of the desires. That power is beyond all calculation, and often beyond all control. The casual imagery of the fancy will pass away, and unless the mind intentionally dwells upon it, cherishes it, and endeavours to recall it, it may even leave no vestige to bring it back again into view; the mere corporal feeling, unless unhappily inflamed by external sources of impurity, may easily be brought into subjection. But when words have been much or long associated with such trains of conceptions or feelings, they will, in various ways, contribute to excite and to strengthen them, and the consequence will often be that purity will be lost, and that the moral, mental, and physical system, will sustain shocks from which they cannot recover.

It is one most injurious effect of that excessive reserve which parents often think necessary on these subjects, that their children are left without any definite knowledge of the mischief which the language of indecency will inevitably produce. Let the parent acquire his child's full confidence, and let him, with no other end in view, than his moral welfare, early give him judicious warning, and repeat this as often as he may think necessary to revive the impression, and the best effect will follow.

We presume not to offer much advice on this subject to *mothers*. A mother possessed of genuine delicacy of mind will not need it; and to others we could be of no service. A daughter grows up so much more under her mother's

PHYSICAL EDUCATION.

eye, than a son can do, and there is, we doubt not, among all but the most abandoned of the female sex, so much more of that "decent *personal reserve* which is the foundation of true delicacy of character," that we hope it can require but common judgment and common care to preserve her purity of mind. A mother who knows, however, the moral dangers of the female sex, even where the general laws of chastity are not violated, will be on her guard in observing every possibility of exposure to them; she will guard the plant of modesty with assiduous care, and will be watchful to preserve it from the noxious influence of the indelicacy of rude ignorance or of impurity. We have reason to think that mothers sometimes allow their daughters a more unrestrained intercourse with servants, or with companions of suspicious delicacy, than prudence can authorize. They never should be exposed to circumstances which may lead them to offend against "decent *personal reserve*." How much the present too common modes of dress will lessen that feeling, every considerate mother must perceive. What those moral dangers are to which we referred, beyond those of impure language, and how fatally they have been experienced, we think a father anxious for the welfare of his daughter, will take proper means of acquainting her to whose fostering care they are to owe their safety. Beyond what we have suggested, we can merely add, that the books which lie in the way of girls of the second period, not only should not be of that kind which must cherish a sickly sensibility, but should be free from every thing at which genuine modesty would blush. And if a visitor should, in their presence, bring forward such ideas, however clothed in the language of elegance, or refined double entendre, he ought to be excluded from their society. That a father should ever do so seems impossible: we wish it were.

But the delicacy we wish to see, "is something nobler than innocence." It is not the delicacy of ignorance, but the purity of imagination and desire. And we are satisfied that this is, in some instances, best preserved by a knowledge of the simple truth. "The ridiculous falsities which are told to children from mistaken notions of modesty, tend very much to inflame their imaginations, and set their little minds to work respecting subjects which Nature never intended they should think of, till the body arrived at some degree of maturity. Children very early see cats with kittens, birds with their young, &c. Why then are they not to be told, that their mothers carry and nourish them in the same way? As there would then be no appearance of mystery, they would never think of the subject more. Truth may always be told to children, if it be told gravely; but it is the immodesty of affected modesty that does all the mischief; and this smoke heats the imagination by vainly endeavouring to obscure certain objects." *Parent's Friend*, vol. i.

Thus far we presume to suppose we have not offended against our own principle. We have hitherto written for parents indiscriminately; but what follows is designed for the eye of the father; and we must here be allowed a little more minuteness.

We do not doubt that the due regulation of the sexual desires is, on the whole, the greatest difficulty in education. The danger of doing too much is, in some cases, almost as great as the danger of doing too little. But the circumstances of the times, including social intercourse, newspaper communications, &c. are such, that nothing, we think, but the blindness of ignorance, or the carelessness of vice, or the excessive caution of unenlightened or indolent timidity, can hesitate in endeavouring to communicate such

impressions respecting the nature and consequences of an illicit or unnatural indulgence of those desires, as may operate altogether to prevent, or most materially to check them.

How early such communications should be made, is a matter of extreme difficulty. We recollect hearing a father say, that he had succeeded in producing in the mind of his son, before the age of puberty, such a detestation of the vice we have more particularly in view, that he felt a full confidence as to his moral restraint. In that process we have as yet had no experience; but we are inclined to suppose, that more will be effectually done by giving only general, though perfectly distinct, cautions, respecting language and actions connected with this subject, and by leaving the more impressive representations till the period when the desires will stand most in need of restraint.

Before the age of twelve, a father will often be able to perceive, in a well-educated boy, the indications of decided moral principle; by which we understand the real and actuating desire to do right, and to avoid every thing wrong. When besides this he has reason to have confidence in his son's purity of mind, (we still mean of imagination and desire,) and also in his prudence, we think a simple judicious communication respecting the delicate structure, and the object of the male organs, would be attended with important advantages. This would lead to a few plain, but impressive statements, respecting the highly injurious and often fatal consequences of the abuse of them; and the necessity of strictly avoiding every thing, in word or action, which might lead to such abuse. With these representations, the father who has successfully cultivated the principles of religion in his son's mind, would add such as would connect with every kind and degree of impurity, the idea of its offending his omniscient heavenly parent. If it have previously been his object to communicate interesting information respecting the structure and functions of the human frame, such a communication as we have mentioned will have no appearance of formality; and it may be introduced by a natural digression from some other connected topic. Some suggestions as to the mode of accomplishing it may be obtained from Dr. Beddoes's fourth Essay; but we would make it a much more simple business. It will require no more knowledge of anatomy, than what any judicious well-informed father may easily gain from different articles of this work, or the common works on the subject; though if he had an injection of the vessels preparing and conveying the seminal fluid, this aided by plates shewing the *internal* structure of the urinary and seminal organs, could not fail to produce a salutary fear of injuring that which simple inspection would prove to be so complex and so delicate.

We need not say, that whatever determination he adopt on this difficult point, he must do his best to keep off from his son those impressions, (from books, pictures, conversation, &c.) which may tend to give a premature excitement to his desires, or to feed them when they spring up in the course of nature; and as he cannot altogether succeed in this, he will endeavour to render them powerless, by such representations as may make them rather shunned than fostered. A parent with any just sense of duty, cannot fail to avoid himself communicating such impressions, or permitting them to be made under his own eye; "Nil dictu sedura visuque hæc limina tangat Intra quæ puer est," should be inscribed in his memory, and made his invariable principle. It is indeed a noble one; and alike important.

With the same object in view, he will sedulously (yet without any formal precepts,) endeavour to prevent all breaches

PHYSICAL EDUCATION.

breaches of that decent personal reserve of which we have spoken; for instance, at the times of bathing, washing, attending to the calls of nature, &c. We do not want to see affected squeamishness, often hiding real indecency; but genuine delicacy and purity. And he will also observe, (with this specific object in view, *viz.* to keep the sexual desires as near as possible within the limits of nature respecting time and strength,) those rules which common prudence and experience suggest, respecting simple diet, active exercise, early rising, &c.

But we will suppose a case in no degree uncommon; that no communication has been made to a youth respecting the evil we have already alluded to, and that his father, or a parental friend, see reason to believe, that all his *indirect* caution has been ineffectual, and that the deleterious practice has been begun which will gradually impair his bodily and mental powers; and, if not prevented in time, will plunge him into irretrievable evils. Can there be any hesitation what course to pursue? Can there, then, be a doubt as to the necessity of opening his eyes to his situation? It must be done with prudence; but we know it may be done with success; and we know, too, that the result may be earnest affectionate gratitude for the communication, and heartfelt satisfaction at having been the means of preserving a fellow creature from the most serious calamities.

Whether the communication should be in conversation or by letter, must be decided by the circumstances of the case; we have known each tried. On the whole we should prefer opening the subject by conversation. It will then be more easy to perceive whether the caution had been necessary, and to what degree. After some interval, a paper might be put into the hands of the youth, containing a brief, but distinct, and impressive statement of the dreadful consequences of the practice; and some simple cautions to aid in checking the tendencies of the mind to it. If this produced its proper effect, it would scarcely be necessary, for a considerable interval, to revert to the subject; but then it might, at least, be expedient. It is, however, by no means desirable to bring it frequently forwards; for though it may be treated as a moral disease, yet there must be a feeling of delicacy (or perhaps we should say of shame) attending it, which could not be worn off without serious injury; add to which, the efficacy of the representations made would lessen by too much repetition. Those external indications which furnished the first ground for apprehension, must, however, be the guide in determining the subsequent steps. The difficulty is in the commencement. And we should add, that in the first conversation every means should be employed, to prevent all conversation on the subject with others; it should be absolutely confined to the individual and his friend.

The parent or tutor may take every preventive caution, (exclusive of direct communication,) may do every thing that enlightened prudence would suggest to preserve strict personal reserve, and keep off the contagion of evil example; and all this completely, and in itself considered successfully; and yet without preventing the evil. Many instances have been known of its commencement without any communication with others, and by circumstances in some sense accidental. We are fully satisfied, taking every thing into account, that it would be best to *forewarn* every boy who possessed a tolerable share of good sense and moral susceptibility. Numerous instances have occurred, in which this practice has been begun and persevered in, till the mischief was almost, if not altogether, irretrievable, without the individual's having been fully sensible of the criminality, and

but little of the most injurious consequences, of "this species of slow suicide."

For the mode of commencing the subject after there were decided grounds of apprehension, we can give no specific directions. We can only say, that it must be done at a suitable time; when the mind seems open; when nothing has occurred to excite suspicion as to the motives; and with that cautious reserve which may give an insight into the real state of the case. Then is a time to give a faithful representation of consequences, &c. A paper for the purpose already suggested, might be of some such nature as the following, which may assist in the first stages also.

We would begin by mentioning, (without of course the slightest personal allusion,) such cases as had occurred to our own knowledge, where loss of sight, total loss of mental and bodily health, and premature death, had followed the continuance of it; and where extremely debilitating involuntary emissions had succeeded the habitual practice of it, even where it had been abandoned. We would then select such compressed statements from books of authority, (and we have seen Tissot often referred to, and in Dr. Beddoes's fourth Essay will be found a striking case, which will urge every considerate parent to early communication,) respecting the common effects of this waste of a fluid designed to answer such important ends in the animal economy, and the early and excessive loss of which must weaken the whole nervous and digestive system, impair the faculties of the mind, and surrender the wretched victim of sensuality to the miseries, infirmities, and decrepitude, of extreme yet infirm old age. We would inform him that it would subject him to convulsions, epileptic fits, palsy, insanity, impotency, tabes dorsalis, corporal emaciation and decay, and partial or even total blindness or deafness; and that where the progress to these calamities had been checked in time, the mental and bodily faculties are usually so injured by any long continuance of it, as to become incapable of any valuable exertion. We would farther tell him, that the bare statement of the natural and necessary effect of this destructive practice, was sufficient to shew the will of God respecting it, even if it do not appear to be expressly forbidden in the scriptures. That it is included in strong expressions of a more general nature, (such as Rom. xiii. 12—14. 1 Cor. iii. 16, 17. 2 Cor. vii. 1. Gal. v. 19—21. 1 Pet. ii. 11., and especially 1 Cor. vi. 9—10.) there can be no doubt; and at any rate that God has forbidden it by the usual course of providence. That its moral effects in destroying the purity of the mind, in swallowing up its best affections, and perverting its sensibilities into this depraved channel, are among its most injurious consequences; and that they are what render it so peculiarly difficult to eradicate the evil. That in proportion as the habit strengthens, the difficulty of breaking it of course increases; and that while the tendency of the feelings to this point increases, the vigour of the mind to effect the conquest of the habit gradually lessens. We would tell him, what we remember a medical professor said, that whatever might be said in newspapers respecting the power of medicine in such cases, nothing could be done without absolute self-control, and that no medicines whatever could retrieve the mischiefs which the want of it had caused. And that the longer the practice was continued, the greater would be the bodily and mental evils it would inevitably occasion. We would then advise him to avoid all situations in which he found his propensities excited, and especially, as far as possible, all in which they had been gratified; to check the thoughts and images which excited them; to shun those associates,

or at least that conversation, and those books, which have the same effect; to avoid all stimulating food and liquor; to sleep cool on a hard bed; to rise early, and at once; and to go to bed when likely to fall asleep at once; to let his mind be constantly occupied, though not exerted to excess; and to let his bodily powers be actively employed, every day, to a degree which will make a hard bed the place of found repose. Above all, we would urge him to impress his mind, (at times when the mere thought of it would not do him harm,) with a feeling of horror at the practice; to dwell upon its sinfulness and most injurious effects; and to cultivate, by every possible means, an habitual sense of the constant presence of a holy and heart-searching God, and a lively conviction of the awful effects of his displeasure.

When entering into the world, where temptations of a different nature will necessarily occur, we would, before his leaving the roof of the parent, then enter into other branches of moral restraint. On this point, however, we have had an opportunity of saying enough already; see *Moral Philosophy*, II. 1. 2. 3. to which we refer the reader.

At the close of *Moral Education*, after a reference to the suggestions we have now brought forwards, we expressed our intention to introduce in this article "a comparative view of the advantages and disadvantages of public and private education." Since this series was commenced, we have, at different times, paid some attention to the subject; but still without the ability to draw up such a view as would prove satisfactory to the reader or to ourselves. We shall once more defer it, and hope to offer it under the head of *SCHOOLS*.

Since the former part of this article was sent to the press, we have had an opportunity of hearing Syer's *Treatise on the Management of Infants* strongly recommended by a professional man, as a truly excellent work; and we think it our duty to mention it for the benefit of our readers. On the subject of this last division, some striking observations will be found in a singular work, entitled "The first Lines of a System of Education, according to Philosophical Principles."

PHYSICIAN, a person who professes the art of preventing and curing diseases. At present the appellation is usually limited to persons who possess the degree of doctor, or bachelor of medicine, and who do not practise surgical operations; since custom has introduced this division into medical practice.

The profession of curing diseases, however, is very far from being confined to these two classes, physicians and surgeons: for, in modern times, both these classes are greatly outnumbered by the apothecaries, or dispensers of medicines, who have, in the course of years, gradually become medical advisers, and have undertaken both the counsel and management of the sick, and the manipulation of remedies. Or perhaps the division may have originated by an opposite progression, in proportion as men of liberal education and enlarged views took up the investigation of the human constitution, and by carrying the principles of science to the mere art, at once augmented the utility of the profession, and gave dignity to the pursuit. The acquirements which are necessary to form the accomplished physician, are, indeed, not comprised within a small compass, and are therefore only to be attained by a careful cultivation of the understanding for a series of years; for without the preparatory and collateral information, the mere medicinal knowledge will, in general, lead but to a blind routine in the steps of the master, and to a limited and often erroneous application of a few unvarying precepts. A

curfory view of the qualifications of the medical character may perhaps, therefore, not be out of place here; the history of the progress of medical opinions and improvements having been already detailed. See *MEDICINE, History of*.

All the works of nature are so intimately connected, that no one part of them can be well understood, by considering and studying it separately. In order, therefore, to be qualified for the practice of physic, a variety of branches of knowledge, seemingly little connected, are nevertheless necessary. The early studies of an individual destined to the profession, should be of that liberal nature which tend to enlarge the views, and to cultivate the reasoning faculty, and a talent for observation; for that quickness of perception and readiness of resource so necessary in the emergencies which often present themselves in practice, can only be perfected by a clear and methodical arrangement of ideas and an extensive knowledge.

Independently of the improvement of the faculties and the refinement of taste, which are derived from the study of the ancient languages, the sources of a physician's information must be very limited, if he is not master at least of the Latin tongue, which has been the universal language of the learned in Europe for so many ages, and serves as the medium of communication between all nations on the subjects of science. The labours of the ablest medical philosophers of Italy, Germany, and France, can only be participated through the medium of that language. The same actual necessity may not exist for a knowledge of the Greek language: but an acquaintance with that copious, expressive, and harmonious tongue, in which some of the oldest, and some of our best authors have written, particularly Hippocrates, the father and founder of medicine, could scarcely be dispensed with, even if almost all the medical terms of art were not derived from it. Ignorance of this language must therefore impede the progress of the medical inquirer; nor can it be deemed becoming a physician to be in the daily use of terms, to the original of which he is a stranger. The progress of medicine and the collateral sciences in France, which during the last half century has been recorded in the vernacular language, renders a knowledge of that tongue now indispensable; and an acquaintance with the German is daily becoming the key to much valuable knowledge.

Thus prepared with the means and instruments for acquiring information, the physician must deem a knowledge of the following sciences essential to his profession. The necessity of a previous knowledge of *anatomy*, or of the structure of the human frame, to the practitioner of medicine is obvious. That very minute acquaintance, however, with the ramifications of every arterial branch, and with the course and insertion of every muscle, so necessary to the surgeon, who is employed to divide and remove different parts by the knife, is scarcely requisite to be retained in the recollection of the physician. To him a correct knowledge of the situation, appearance, structure, and connection of the more important organs is, however, not to be dispensed with. The best anatomists, like the best mechanists of watches and other machines, will be best able to replace or remove what is morbid or deranged, *i. e.* will be necessarily the best *operating surgeons*; but it is obvious that the person best acquainted with the structure of parts, not to be approached by mechanical means, is not necessarily the greatest adept in ascertaining their diseases, which are learnt from a knowledge of *symptoms* only, nor of curing them by the indirect operation of medicines.

For the purpose of ascertaining the seat and nature of the diseases

PHYSICIAN.

diseases of parts not under the view of the eye, nor within the reach of the hand, the two branches *physiology* and *pathology* are requisite: and these, especially the first, comprehend various other branches of knowledge which might appear unconnected with them.

Physiology comprises the doctrine of all the functions of the animal body in its healthy state; as well as of the nature and composition of the fluids, their production, uses, and discharges. For the proper comprehension of these matters, the whole range of *natural philosophy* is indispensably necessary. "When you inquire into this subject," says Dr. Gregory, "you find the human body a machine, constructed upon the most exact mechanical principles; in order, then, to understand its movements, you must be well acquainted with the principles of *mechanics*. Considering the human body in another view, you find fluids of different kinds circulating through tubes of various diameters; the laws of their motions, therefore, cannot be understood without a knowledge of *hydraulics*. The eye appears to be an admirable optical machine; and of course the phenomena of vision cannot be explained without a knowledge of the principles of *optics*. As the human body is surrounded with an elastic fluid, the air, subject to various changes in respect of gravity, heat, moisture, and other qualities which have great influence on the constitution, it is proper to be acquainted with the nature and properties of this fluid, the knowledge of which constitutes the science of *pneumatics*. It were easy to bring many more examples to shew how necessary a knowledge of the various branches of natural philosophy is to the right understanding of the animal economy." See Dr. John Gregory's Lectures on the Duties and Qualification of a Physician, p. 73.

But there are many other phenomena of the animal economy, which are not explicable on the principles of mechanical philosophy. Various changes are induced upon the fluids, which chemical science can alone explain. The production of different fluids from one source, their qualities and nature, are not indeed as yet fully ascertained; but chemical analysis affords the only source of investigation. It is, therefore, necessary to be acquainted with the chemical history of our fluids; and still more requisite to know the chemical qualities of numerous substances which are taken into the human body as food, drink, medicine, and poison. The necessity of a knowledge of *chemistry*, therefore, previous to the study of the practice of physic, is obvious.

Yet the most accurate knowledge of anatomy, of mechanical philosophy and chemistry combined, will be insufficient to explain all the phenomena of the animal economy. The animal machine differs in many important circumstances from an inanimate one. An internal principle directs and influences most of the operations of the body, by a set of laws totally distinct from, and independent of, any principles of mechanics or chemistry hitherto known. It possesses the power of motion within itself, and even of modifying and resisting the operation of ordinary chemical agents: it has likewise the power of removing its own disorders, and of rectifying many deviations from its natural state; as in the case of fractured bones, of the incarnation of wounds, of the enlargement of one organ when another is destroyed, &c. It must be obvious, therefore, notwithstanding the many attempts that have been made to explain the phenomena of the animal body upon mechanical and chemical principles alone, that such a doctrine must be altogether imperfect.

A new and interesting investigation, therefore, presents itself to the physiologist, and one of the most intricate and difficult pursuit; namely, an inquiry into the laws of the

nervous system, or of that faculty of living beings which has been called the *vital principle*, *sensorial power*, *nervous energy*, &c. (See EXCITABILITY, and LIFE.) On this power depend all the faculties of sensation and motion; the phenomena of the circulation of the blood from the moving powers of the heart and arteries; those of respiration, and the changes which that function produces on the blood, on the brain and organs of sense, and on the temperature of the body; and, consequently, the phenomena of digestion, absorption, nutrition, secretion, (as of bile, saliva, tears, urine, &c.), and excretion (as of the intestinal fæces, of perspiration, mucus, &c.), which are the result of the circulation of the blood. In order to illustrate the nature of these functions of the human body, a knowledge of the *comparative anatomy* of other animals is requisite. Many important discoveries in the animal economy have originated in experiments first made upon brutes, which could not have been made upon the human subject; for example, the experiments relating to the circulation of the blood, respiration, muscular motion, the sensibility and irritability of different parts of the body, and the effects of various medicines.

It belongs, moreover, to physiology to trace the diversity of the human constitution in different individuals, circumstances, and climates, arising from age, sex, manner of living, and original temperaments or habits of body; inasmuch as diseases are much influenced, as well as the operation of remedies, by these varieties. For the same reason, it is also requisite to inquire into the laws relating to the mutual influence of the mind and body upon each other. This leads to an extensive and interesting subject, the history of the faculties of the human mind; which, if we are not on our guard, is apt to carry us insensibly into a labyrinth of metaphysics. How important, however, the study of these laws is to the physician, may be demonstrated in considering the power of habit, the effects of enthusiasm, the force of the imagination, and the influence of the principle of imitation, on the functions and diseases of the body. See HABIT; IMAGINATION, *Influence of, on the Corporeal Frame*; and IMITATION, *Principle of, in Medicine*.

All these branches of knowledge, however, may be considered as preliminary to the great object of the physician, which is the discrimination and cure of diseases. When he is well acquainted with the nature and functions of the living body in its healthy state, he will be prepared to investigate them in a state of disease. *Pathology*, which delivers the general doctrine of the causes, symptoms, and effects of diseases, is obviously built upon *physiology*. The mode in which the seat and nature of diseases are to be ascertained from their symptoms and progress, and the indications to be deduced from them, have been detailed at length under the proper head. (See DISEASE.) The general doctrines to be observed in the cure of diseases, and the general nature of the remedies to be employed, constitute the *therapeia*, or *therapeutics*; which comprises a knowledge of the *Materia Medica*, or of the substances, natural and factitious, that are administered to the sick, and of their qualities and effects. In this branch of medicine, the necessity of a knowledge of *chemistry* is again apparent, since many of the most active and valuable agents are the products of this art; and the science of *botany*, so far as it facilitates the knowledge of the plants which are used in diet or medicine, is likewise subservient to therapeutics.

Thus copiously stored with all the information above alluded to, the physician is prepared to acquire experience, by observing the various symptoms of diseases, and the operations of medicines, during his attendance on the sick: and let it be remembered, that it is only upon such

a founda-

a foundation that real *experience* can be built. Experience does not consist in *seeing* a great number of diseases: for if it were so, the best physician in the world would be an old nurse in a large hospital, who sees the daily and hourly progress of every species of malady. Yet how contracted the views, how limited the resources of such a person! how mechanical and unvarying are the few rules of practice which are thus acquired! Yet such is, in fact, the sum of the *experience* which a whole life of practice affords to those who presume to enter the profession of medicine, without that preliminary education, which alone fits the mind for *observation*, the only foundation of true experience. A person may be taught many of the practical arts of life, to a certain extent, without any knowledge of their principles. He may learn to navigate a ship, in a certain course, with little knowledge of the principles of navigation; or he may make a dial without any acquaintance with astronomy, or spherical trigonometry: so he may be taught, behind the counter of an apothecary's shop, half a dozen apozems for the cure of a cough or a diarrhoea. But order such a navigator to steer a new course, or such a diallist to take a new aspect; and from a total deficiency in the *first principles* of their respective arts, they are altogether unable to succeed. Still more difficult is it to be successful in the cure of diseases, without a knowledge of first principles; because the circumstances of diseases are perpetually varying; and the same symptom, a cough or diarrhoea for instance, are indicative of very different states of disease, and will be materially injured in one instance by the very remedy which proved curative in another. (See COUGH.) Throughout the practice of medicine, indeed, a resort to general principles is perpetually necessary, since no two cases of disease are exactly similar. Many diseases, it is true, are obvious in their causes, appearances, and treatment, and, if not actually mismanaged, have a natural tendency to terminate in health; but on the other hand, many serious maladies assume at first a common form, and it requires no little sagacity to trace them in the bud, and no little knowledge to obviate their fatal consequences.

It is not, however, enough to possess knowledge; but the mind should be able at once to bring in review the knowledge which it retains, and should be ready and active in its application. It is often necessary to adopt at once a plan, and to pursue it with active decision: it is necessary to weigh contending difficulties, and at once to seize the path where the fewest or least important appear, or where the inconveniences are counterbalanced by the advantages. It is not always easy for the observers to estimate the value of such decision in the physician; for this rapidity is often equally the offspring of ignorance: because no difficulty can be experienced by those who are not able to anticipate consequences; and doubt, the consequence of different resources contending for superior eligibility, can scarcely be felt by those who have no plan at all. Physicians are called on, in general, to act with this prompt decision; and to hesitate is usually accounted a mark of ignorance. A man must have merited the confidence of the world before he can claim time for consideration, and his reputation must be firmly established, before he can own himself at a loss. This necessary readiness of resource is partly owing to habit and experience, but principally to a methodical arrangement and clear distinct views of the knowledge treasured in the mind. The able and experienced physician, who can at once comprehend the object to be attained, will, at the same moment, perceive the various methods by which it can be effected, and he has only to chuse the most convenient and the best adapted to the habit or idiosyncrasy

of his patient. In his progress new views will probably open, and the soundest judgment is shewn in steering between the opposite extremes, of varying the plan according to the variety of symptoms, or obstinately persisting in it, notwithstanding every change of appearances. The first is pleasing to common observers, as it shews a diligent attention; but it is a proof of weakness and indecision. The last, perhaps the most venial error, is the effect of too great confidence; and, unless accompanied with extensive knowledge which dictated the first opinion, and an acute sagacity in discerning the effects of medicines, is scarcely less injurious.

It seems obvious, then, that a complicated art, like that of medicine, can only be acquired by the union of extensive information, with diligent observation, and that much evil is likely to ensue where it is practised without these qualifications. Absurd as is the notion of universal remedies, or of any given remedy for any one disease nominally the same, the extent of quackery seems, however, to be increasing, partly from the revenue which government derives from it, but very much also from the acknowledged imperfection of the medical art in the hands of so many half-qualified practitioners. To conclude, however, in the words of that able and estimable physician before quoted; "On the whole, it will appear, that a physician, who understands the principles of his profession, who has an extensive acquaintance with every branch of natural knowledge connected with it, who properly applies his knowledge, and who has genius and attention equal to others, must have a great advantage, as a practical physician, over one who is ignorant of the principles of medicine, and of the sciences connected with it. Genius and sense are, indeed, the peculiar gift of heaven, and cannot be acquired by the most extensive learning, or the greatest efforts of industry. But with these assistances, genius and sense are capable of the highest improvements." Gregory's Lectures, before quoted, p. 87. See also Parr's London Medical Dictionary, art. *Medicine*; and Percival's Medical Ethics.

PHYSICIANS, *Dogmatical*, called also *rational*, among the ancients, were those who endeavoured to reduce their knowledge of diseases to certain principles. The *dogmatic* physicians were in opposition to the *empirics*. See EMPIRIC.

PHYSICIANS, *Empirical*, properly signify those who rely upon experience, and are directed by it in practice. An ancient sect of this appellation was opposed to the *dogmatic* or *rational* sect; and the principles of both are admirably detailed and criticised by the elegant Celsus. De Medicinâ, Præf. See EMPIRIC.

PHYSICIANS, *Methodical*, a sect of physicians of Rome, who refused to adopt the doctrines either of the *dogmatic* or *empiric* sect. See METHODISTS, in *Medical History*.

PHYSICIANS, *Galenic*, a distinction assumed by those physicians after the revival of learning, who prescribed only vegetable medicines, and their preparations. They stood in opposition to the *chemical* or *spagirical* physicians, who employed the preparations of metals and minerals procured by chemistry. See GALENICAL.

PHYSICO-MATHEMATICS, includes those branches of physic, which, uniting observation and experiment to mathematical calculation, undertake to explain the phenomena of nature. See MIXED MATHEMATICS.

PHYSICS, PHYSICA, *φυσική*, derived from *φύσις*, nature, sometimes also called *physiology*, and *natural philosophy*, is the doctrine of natural bodies, their phenomena, causes, and effects, with their various affections, motions, operations; &c.

PHYSICS.

Mr. Locke would likewise have God, angels, and spirits, comprehended under physics; but these are more usually referred to metaphysics.

The immediate and proper objects of physics, are body, space, and motion.

The origin of physics is referred by the Greeks to the Barbarians, *viz.* the Brachmans, Magi, and the Hebrew and Egyptian priests.

From these it was derived to the Greek sages or sopheri, particularly to Thales, who is said to have first professed the study of the phenomena of nature in Greece. He supposed water to be the general principle from which all material things are formed, and into which they are resolved: he particularly noticed the properties of the magnet, which had been before observed to attract iron, as well as the effect of friction in exciting the electricity of amber; and to both of these substances he attributed a certain degree of animation, which he considered as the only original source of any kind of motion. (See THALES.) Anaximander (see his biographical article) appears to have directed some attention to meteorology; he derived the winds from the rarefaction of the air produced by the operation of heat; and he attributed thunder and lightning to the violent explosion or bursting of the clouds, which he seems to have considered as bags, filled with a mixture of wind and water. The same erroneous notion was entertained by Anaximenes (see ANAXIMENES), who compared the light attending the explosion, to that which is often exhibited by the sea, when struck with an oar. Pythagoras is said to have reasoned on physical effects in a manner too mathematical and visionary to entitle him to be ranked among those who have investigated the minute operations of nature. (See PYTHAGORAS.) For the opinions of Anaxagoras and Democritus, see their respective articles. Thales had supposed water to be the first principle of all things, and Anaximenes air. Heraclitus fixed on fire as the basis of his system, attributing to it the property of constant motion, and deriving all kinds of grosser matter from its condensation in different degrees. (See HERACLITISM.) It is observed by Bacon, in his essay on the opinions of Parmenides, that the most ancient philosophers, Empedocles, Anaxagoras, Anaximenes, Heraclitus, and Democritus, submitted their minds to things as they found them; but Plato made the world subject to ideas, which he supposed to exist independently of the human mind, and of the external world, and to compose beings of different kinds, by their union with an imperfect matter. Aristotle made even ideas, as well as other things, subservient to words; the minds of men beginning, in those times, to be occupied with idle discussions and verbal disputations, and the correct investigation of nature being wholly neglected. Plato, however, entertained some correct notions concerning the distinction of denser from rarer matter by its greater inertia; and it would be unjust to detract from the extraordinary merit of Aristotle's experimental researches, in various parts of natural philosophy, and more especially from the information contained in his works on natural history. Aristotle attributed to fire absolute levity, and to the earth gravity, considering air and water as of an intermediate nature. (See PLATO and ARISTOTLE.) For an account of the opinions of Epicurus, see EPICUREANS. The works of the ancients, though scarcely any one of their opinions and conjectures was scientifically established on sure foundations, furnish nevertheless a variety of detached facts and observations, that have either led to modern experiments and discoveries, or that have been confirmed by them. Such especially is the fact recorded by Protagorides of Cyzicum, quoted

by Athenæus, who relates, that in the time of king Antiochus, it was usual, as a luxury, to cool water by evaporation: and also the phenomenon noticed by the ancients, that water usually froze the more readily for having been boiled.

The era of the revival, or perhaps we may justly say, of the commencement of physical discoveries, was the 13th century; to which period we may refer the famous Roger Bacon; Hugo Bertius, who is said to have described the polarity of the magnetic needle, though some suppose that the description of it was contained in verses attributed to Guyot, a French poet, who lived about the year 1180; Gioja of Amalfi, who first employed the compass in navigation about the year 1260; Peter Adiger, who mentions the declination of the needle from the true meridian in a manuscript bearing date 1269 (see MAGNET); and the poet Dante, who, about the close of this century, distinguished himself by his philosophical, as well as literary works, and who has given an essay on the nature of the elements. Amongst the philosophers of later date, to whom the sciences, comprehended under the head of Physics, are indebted, we might mention Dr. Gilbert of Colchester, who flourished about the close of the 16th century, and to whose writings on magnetism and electricity we have referred under those articles. The change or variation of the declination of the needle, the discovery of which has been commonly ascribed to Gellibrand, in 1625, must have been inferred, says Dr. Young, from Gunter's observations, made in 1622, if not from those of Mair, or of some other person as early as 1612; for at this time the declination was considerably less than Burrows had found it in 1580. In the beginning of the 17th century lord Bacon acquired, by his laudable efforts to explode the incorrect modes of reasoning which had prevailed in the schools, the just character of a reformer of philosophy: but his discoveries were neither numerous nor striking. In 1620, he proposed an opinion, with respect to heat, which appears to have been then new, inferring from a variety of observations, detailed in his "Novum Organum," that it consisted in "an expansive motion, confined and reflected within a body, so as to become alternate and tremulous: having also a certain tendency to ascend." A similar opinion, respecting the vibrating nature of heat, was suggested, about the same time, by David Gorlaeus, and it was afterwards adopted by Descartes, as a part of his hypothesis, concerning the constitution of matter. (See CARTESIANISM.) In the year 1620 Cornelius Drebel invented a method of measuring the degrees of heat by a thermometer, which, in its first and imperfect state, was a very important instrument; but it was much improved at the close of the century by Dr. Hooke's discovery of the permanency of the temperature of boiling water; which afforded a correct and convenient limit to the scale on one side, as the melting of snow served for fixing a similar point on the other. The true course of the circulation of the blood was discovered by Dr. Harvey in 1628. (See CIRCULATION of the Blood.) In the middle of the 17th century the barometer was invented by Torricelli; the variation of the atmospheric pressure was discovered by Descartes; and Pascal made several experiments which led to the method of determining heights by barometrical observations. (See AIR, ATMOSPHERE, and BAROMETER.) We pass over the observations of Gesner and Aldrovandus with respect to the animal kingdom, and those a century later of the Bauhins, on the vegetable kingdom: and also of Ray and Willughby, Tournefort and Reaumur; and proceed to mention, that the latter half of the 17th century was rendered a very interesting period in the his-

tory of natural knowledge by the establishment of the philosophical societies of Europe; such were the Royal Society of London, in which Boyle, Hooke, Halley, and Newton, distinguished themselves; and the Academy of Sciences at Paris; and also, though of less extent and shorter duration, the Florentine Academy del Cimento. (See ACADEMY and SOCIETY.) In the middle of the 18th century the science of electricity was diligently cultivated by Stephen Gray, Hauksbee, Dufay, Winkler, Nollet, Muschenbroek, Franklin, Wilton, Canton, Henly, &c. &c. (See ELECTRICITY.) The celebrated Linnæus, in his system of botany and zoology, has contributed in a very eminent degree towards bringing near to perfection the logic and phraseology of natural history; nor has he wholly neglected the philosophy of the science. His successors have acquired distinguished merit in these departments of science; but it would be almost endless to recount the names even of those who have most excelled: among whom we may reckon Buffon, Spallanzani, Daubenton, Geoffroy, Pennant, the Jussieus, Lacepede, Haüy, Bergmann, Kirwan, Werner, Shaw, Smith, &c. &c.

The absorption of heat, during the conversion of ice into water, appears to have been separately observed by De Luc, Black, and Wilke, about the year 1755. On this experiment Dr. Black principally founded his doctrine of latent heat, supposed to be retained in chemical combination by the particles of fluids. Dr. Irvine and Dr. Crawford explained the circumstances somewhat differently, by the theory of a change of capacity for heat only. Bergmann, Lavoisier, Seguin, Kirwan, Laplace, and many other philosophers, have illustrated, by experiments and calculations, the various opinions which have been entertained on this subject; and few chemists, from the times of Boerhaave, Stahl, and Scheele, to those of Priestley and other later authors, have left the properties of heat wholly unnoticed. For an account of the elegant hypothesis of Aepinus respecting magnetism and electricity, founded in a great measure on the theory of Franklin, and advanced in 1759, we refer to MAGNETISM and ELECTRICITY. The electrophorus of Wilke, and the condenser of Volta, are among the earliest fruits of the cultivation of a rational system of electricity. (See ELECTROPHORUS and CONDENSER.) Mr. Cavendish's investigation of the properties of the torpedo may serve as a model of accuracy and precision in the conduct of experimental researches. (See TORPEDO.) The speculations of Boscovich respecting the fundamental properties of matter, and the general laws of the mutual action of bodies on each other, (see MATTER,) have been considered by some candid judges as deserving the highest commendation: they remain, however, says Dr. Young, almost in all cases speculations only; and some of the most intricate of them, being calculated for the explanation of some facts which have perhaps been much misunderstood, must consequently be both inaccurate and superfluous. The attention of several experienced philosophers, now living, has been devoted, with much perseverance, to the difficult subject of hygrometry: such are De Luc, Sauffure, Piçet, and Dalton. For some years past, the discoveries of Galvani, Volta, and others, have commanded particular attention; for an account of which, see *Galvanic BATTERY*, GALVANISM, and VOLTAISM. Count Rumford has not only contributed to the extension of physical science by his own experiments and observations relating to light and heat, and also other subjects, but by his establishment of a prize medal to be given at the interval of every three years by the Royal Society to the

author of the most valuable discovery concerning heat or light. Professor Leslie entitled himself to one of these medals by his interesting discovery of the different properties possessed by surfaces of different kinds, with regard to the emission or reception of radiant heat. Perhaps, however, says Dr. Young, none of the modern improvements in speculative science deserve a higher rank than Dr. Herschel's discovery of the separation of heat from light by refraction. M. Prévost has made some just remarks on the experiments of other philosophers respecting heat; and his own theory of radiant heat, and his original investigations on the effects of the solar heat on the earth, have tended materially to illustrate the subject of his researches. The general laws of the ascent and descent of fluids in capillary tubes, and between plates of different kinds, had been long ago established by the experiments of Hauksbee, Jurin, and Muschenbroek (see ASCENT of *Fluids*, and CAPILLARY *Tubes*): many other circumstances, depending on the same principles, had been examined by Taylor, Achard, and Guyton; and some advances towards a theory of the forms assumed by the surfaces of liquids, had been made by Clairaut, Segner, and Monge. Dr. Young, in an essay on the cohesion of fluids; read before the Royal Society in the year 1804, has reduced all effects of this nature to the joint operation of a cohesive and repulsive force, which balance each other; assuming only that the repulsion is more augmented by the approach of the particles to each other than the cohesion: and he has thus discovered a perfect correspondence between many facts, which had not been supposed to have the slightest connection with each other. About a year after the publication of this paper, M. Laplace read to the National Institute at Paris a memoir on capillary tubes, in which, as far as he has pursued the subject, he has precisely confirmed the most obvious of Dr. Young's conclusions, although his mode of calculation appears, in our author's judgment, to be by no means unexceptionable, as it does not include the consideration of the effects of repulsion.

Dr. Young, of whose history of Terrestrial Physics in the first volume of his "Course of Lectures on Natural Philosophy and the Mechanical Arts," we have availed ourselves in the compilation of this article, closes his history with the following observations. "When we reflect on the state of the sciences in general, at the beginning of the 17th century, and compare it with the progress which has been since made in all of them, we shall be convinced that the last two hundred years have done much more for the promotion of knowledge, than the two thousand that preceded them: and we shall be still more encouraged by the consideration, that perhaps the greater part of these acquisitions has been made within fifty or sixty years only. We have therefore the satisfaction of viewing the knowledge of nature not only in a state of advancement, but even advancing with increasing rapidity; and the universal diffusion of a taste for science appears to promise, that, as the number of its cultivators increases, new facts will be continually discovered, and those, which are already known, will be better understood, and more beneficially applied. The Royal Institution, with other societies of a similar nature, will have the merit of assisting in the dissemination of knowledge, and in the cultivation of a taste for its pursuit; and the advantages arising from the general introduction of philosophical studies, and from the adoption of the practical improvements depending on them, will amply repay the labours of those, who have been active in the establishment and support of associations so truly laudable."

Physics may be divided, with regard to the manner in which it has been treated, and the persons by whom, into

PHYSICS, *Symbolical*, or such as was couched in symbols: such was that of the old Egyptians, Pythagoreans, and Platonists, who delivered the properties of natural bodies under arithmetical and geometrical characters, and hieroglyphics.

Peripatetical, or that of the Aristotelians, who explained the nature of things by matter, form, and privation, elementary and occult qualities, sympathies, antipathies, attractions, &c. See **ARISTOTELIAN** and **PERIPATETICS**.

Experimental, which inquires into the reasons and natures of things from experiments, such as those in chemistry, hy-

drostatics, pneumatics, optics, &c. See **EXPERIMENTAL Philosophy**.

And finally, *mechanical*, or *corpuscular*, which explains the appearances of nature from the matter, motion, structure, and figure of bodies, and their parts: all according to the settled laws of nature and mechanics. See **MECHANICAL** and **CORPUSCULAR Philosophy**.

PHYSIOGNOMICS, a term used by some physicians and naturalists, for such signs as are taken from the countenance to judge of the state, disposition, &c. of the body and mind.

PHYSIOGNOMY, φυσιογνωμια, formed from φυσικη, nature, and γνωσκα, I know, the art of knowing the humour,

PHYSIOGNOMY.

temperament, or disposition of a person, from observation of the lines of his face, and the characters of its members or features; or of designating the powers and dispositions of the mind by a peculiar combination of the features.

Baptista Porta and Robert Fludd, to whom we may add in later times, Gall, Camper, Lavater, and Blumenbach, are the best modern authors on physiognomy. The ancient ones are the sophists Adamantius and Aristotle: the physiognomy of which last we have translated into Latin by de Lacuna.

With respect to physiognomy, this at least may be said, that of all the fanciful arts of the ancients, disused for a considerable time, but lately revived among the moderns, there is none has so much foundation in nature as this.

There is an apparent correspondence between the face and the mind: the features and lineaments of the one are directed by the motions and affections of the other; there is even a peculiar arrangement of the members of the face, and a peculiar disposition of the countenance, corresponding to each particular affection of the mind.

In effect, the language of the face, physiognomy, as the zealous advocates of this art pretend, is as copious, nay, perhaps, as distinct and intelligible, as that of the tongue, speech. In other words, it is plain to the most inattentive observer, that each individual of the human race possesses a set of distinctive marks in the form of the head, and the outlines of the countenance: in proof of which we refer to the articles CRANIOLOGY, CRANIUM, and MAN. It is also well known and universally allowed, that these marks insensibly lead us to form conclusions as to the nature and inclinations of persons at the first sight, or on the slightest acquaintance with them; which notions are sometimes just, but often erroneous.

The foundation of physiognomy, as some have stated it, is this: the different objects that present themselves to the senses, nay, the different ideas that arise in the mind, do each make some impression on the spirits; and each an impression correspondent or adequate to its cause: therefore each makes a different impression.

If it be asked, how such an impression should be effected, it is easy to answer, that it follows from the economy of the Creator, who has fixed such a relation between the several parts of the creation, to the end that we may be apprized of the approach or recess of things useful or hurtful to us.

The animal spirits, say the Cartesians, moved in the organ by an object, continue their motion to the brain: whence that motion is propagated to this or that particular part of the body, as is most suitable to the design of nature; having first made a proper alteration in the face, by means of its nerves, especially the pathetici, and oculorum motorii.

The face, here, does the office of a dial-plate; and the wheels and springs, withinside the machine, actuating its muscles, shew what is next to be expected from the striking part.

Now if, by repeated acts, or the frequent entertaining of a favourite passion, or vice, which natural temperament was hurried, or custom dragged one to, the face is often put in that posture which attends such acts; the animal spirits will make such patent passages through the nerves (in which the essence of an habit consists), that the face is sometimes unalterably set in that posture (as the Indian religious are by a long continued sitting in strange postures in their pagods); or, at least, it falls, insensibly and mechanically, into that posture, unless some present object distort it therefrom, or some dissimulation hide it; and this reasoning, it has been said, is confirmed by observation; which, y being a little

more accurate and minute, would serve to distinguish not only habits and tempers, but even professions. After all, this is a kind of science which must be very precarious and delusive. (See LAVATER.) It should therefore be exercised with great judgment and discretion; otherwise we may deduce from it conclusions that are equally unfounded and injurious. To the observations on the theory of this science already introduced under the articles to which we have above referred, we shall here subjoin an account of the system of Lavater, which not long ago excited the public curiosity, though it is now almost forgotten.

Lavater asserts, that "each creature is indispensable in the vast compass of creation; but each individual," he adds, "is not alike informed of the truth of this fact, as man only is conscious that his own place cannot be supplied by another." The idea thus conceived, he thinks one of the best consequences of physiognomy, and he exults, that the most deformed and wicked persons are still superior to the most perfect and beautiful animal, because they always have it in their power to amend, and in some degree to restore themselves to the place assigned them in creation; and however their features may be distorted by the indulgence of their passions, still the image of the Creator remains, from which sin only is to be expelled, to render the likeness nearer perfection. In pointing out the distinguishing traits that discriminate the natives of different regions, Lavater observes, that the placing of several persons together, selected from nations remotely situated from each other, gives at one glance their surprising varieties of visage; and yet he acknowledges that to point out those variations is a task of considerable difficulty, and his assertion, that this may be done with more facility from an individual than the mass of population, seems extremely probable. The French, he thinks, do not possess equally commanding traits with the English, nor are they so minute as those of the Germans, and it is to the peculiarities of their teeth, and manner of laughing, that he attributed his power of deciding on their origin. The Italians he appropriated by the form of their noses, their diminutive eyes, and projecting chins. The eye-brows and foreheads are the criterion by which to judge of the natives of England. The Dutch possess a particular rotundity of the head, and have weak, thin hair: the Germans, numerous angles and wrinkles about the eyes and in the cheeks; and the Russians are remarkable for black and light coloured hair, and flat noses.

It must be extremely grateful to the natives of England to reflect, that Lavater considers them, in the aggregate, the most favoured upon the earth with respect to personal beauty; he says, they have the shortest and best arched foreheads, and that only upwards, and towards the eye-brows, sometimes gradually declining, and in other cases are rectilinear, with full, medullary noses, frequently round, but very seldom pointed, and lips equally large, well defined, curved, and beautiful, with the addition of full round chins. Still greater perfections are attributed to the eyes of Englishmen, which are said to possess the expression of manly steadiness, generosity, liberality, and frankness, to which the eye-brows greatly contribute. With complexions infinitely fairer than those of the Germans, they have the advantage of escaping the numerous wrinkles found in the faces of the latter, and their general *contour* is noble and commanding.

Judging from the ladies he had seen of our country, and from numerous portraits of others, Lavater was led to say, they appeared to him wholly composed of nerve and marrow, tall and slender in their forms, gentle, and as distant from coarseness and harshness as earth from heaven. His own countrymen he found to have many characteristic

PHYSIOGNOMY.

varieties: those of Zurich are generally meagre, and of the middle size, and either corpulent or very thin.

To pursue this subject something further, it will be found, that the people of Lapland, and parts of Tartary, are of very diminutive stature, and of extremely savage countenances, formed by flat faces, broad noses, high cheek-bones, large mouths, thick lips, peaked chins, and their eyes are of a yellow brown, almost black, with the lids retiring towards the temples; nor are the females of this disagreeable race more favoured by nature; and each sex is distinguished by the grossest manners, and minds stupid beyond credibility; but of all the varieties of the human species, the inhabitants of the coast of New Holland seem the most debased and miserable; those are tall and slender, and to add to the deformity of thick lips, large noses, and wide mouths, they are taught from their infancy to keep their eyes nearly closed, to avoid the insects which swarm around them.

Turning to the more favourable side of this picture of national physiognomy, we shall find the people of Cachemire, the Georgians, the Circassians, and Mingrelians, erect, noble, and formed for admiration, particularly the females, whose charms of face and person are proverbial.

There are too many local and physical causes for this difference in the external appearance of the inhabitants of the different parts of the world, for enumeration and explanation in so confined a space as that to which we are limited. Professor Kant, of Konigsberg, in an essay on this subject, divides the human race into four principal classes, into which the intermediate gradations may readily be resolved: those are the Whites, the Negroes, the Huns, (Monguls or Calmucs,) and the Hindoos, or people of Hindoostan. Circumstances purely external may be the accidental, but cannot be the original causes of what is assimilated or inherited: as well could chance produce a body completely organized. "Man," says the professor, "was undoubtedly intended to be the inhabitant of all climates and all soils. Hence the seeds of many internal propensities must be latent in him, which shall remain inactive, or be put in motion according to his situation on the earth: so that in progressive generation, he shall appear as if born for that particular soil in which he seems planted."

In the opinion of this gentleman, the air and the sun are the two causes which most powerfully influence the operations of propagation, and give a lasting development of germ and propensities, or in other words, the above powers may be the origin of a new race.

Food may produce some slight variations; these, however, must soon disappear after emigration, and it is evident, that whatever affects the propagating powers, does not act upon the support of life; but upon the original principle, the very source of animal conformation and motion. It has been observed, that man degenerates in stature and faculties the nearer he is situated to the frigid zone: this seems a necessary consequence of that situation, for this obvious reason; were men of the common stature in those regions of extreme cold, the impelling power of the heart must be increased, to force the blood through the extremities, which would otherwise chill, and become totally useless; but as the Creator did not think it useful to adopt this mode of preserving the limbs, they have been shortened, for the purpose of confining the circulating fluid to the trunk, where the natural heat accumulating, the whole body has a greater proportion of that comfortable sensation than strangers feel when visiting those northern countries.

The propensity to flatness, observable in the prominent parts of the countenance of the persons under consideration, exposed to the effects of cold, is accounted for by that very

circumstance; and it appears probable, that their high cheek-bones, and small, imperfect eyes are so contrived, to preserve the latter from the piercing effects of the wind, and the offensive brilliancy of the almost eternal snows. The abbé Winkelman attributes the enormous and disgusting lips of the Negroes to the heat of the climate they inhabit; others account for the blackness of their skin by supposing "the surplus of the ferruginous, or iron particles, which have lately been discovered to exist in the blood of man, and which, by the evaporation of the phosphoric acidities, of which all Negroes smell so strong, being cast upon the retiform membrane, occasions the blackness which appears through the cuticle, and this strong retention of the ferruginous particles seems to be necessary, in order to prevent the general relaxation of the parts."

In pointing out the distinguishing traits that discriminate the natives of different regions, Lavater observes, that a person deeply enamoured of another, and thinking intensely on the form and position of their features, might assume a resemblance of the admired object, though miles of space intervened between them; and pursuing his mental dream, he adds, that it is equally probable an individual meditating revenge in secret, may compose his countenance into a likeness of him who was to be its victim. The incorrectness of the latter fancy may be exposed by merely observing that the person under the influence of the passion of revenge, must bear in his countenance the lines expressive of that restless affection; now as the object intended to be injured is unconscious of the secret machinations against him, he may at the instant be engaged in some benevolent pursuit, or may feel some internal joy which moulds his features into an expression directly opposite to that of his adversary, who may have generally seen him thus; for revenge is often aimed by the wicked at the best of men: consequently, the countenance of a fiend grinning with malice cannot at the same time beam with a complacency arising from a set of features entirely unruffled.

Before we enter upon a description of the marks which, according to Lavater, point out the character of the possessor, it may be proper to give one or two instances of the fallacy, and of the truth, of the conclusions drawn from them, in order that our readers may form their own conclusions, as to the folly or propriety of entertaining a propensity to form a judgment of mankind from the shapes of their noses, eyes, foreheads, and chins.

M. Sturtz declared to Lavater, that he "once happened to see a criminal condemned to the wheel, who, with fanatic wickedness, had murdered his benefactor, and who yet had the benevolent and open countenance of an angel of Guido. It is not impossible, adds this gentleman, to discover the head of a Regulus among guilty criminals, or of a vestal in the house of correction." Lavater admits this assertion in its fullest extent, but his reasoning to reconcile it to his system is by no means conclusive.

When we hear of any atrocious act, the natural abhorrence of vice and cruelty implanted in us, leads the imagination to form a portrait of the perpetrator, suited to the deformity of the mind capable of committing it; without reflecting, that had such an index existed in the countenance of the abhorred object, it is most probable, his murderous and horrible exterior would have placed mankind so far on their guard as to detect his intentions. Upon viewing the culprit, we are perhaps surprised to find that there is nothing particularly indicative of cruelty in the outlines of his face, and we indolently endeavour to force each into the immediate form of our preconceived portrait; this occasions us to read lurking villainy in his eyes, and converts the wrinkles

PHYSIOGNOMY.

kles of disease, or approaching age, into the frown of a dæmon; and we depart exclaiming against the striking contour of the miserable wretch, when, perhaps, many of our friends, and even relatives, would suffer by a comparison, and yet had led uniformly innocent lives. On the other hand it must be admitted, that vice generally stamps her votaries with marks, which may be known at a glance, but this admission applies only to the confirmed enemies of virtue, those whose habits of living are so uniformly vicious, that very little propriety occurs in their conduct.

The following anecdote, related by Lavater, may serve as a partial illustration of the assertion, that the features are affected by the turn of the mind, or, perhaps, more correctly speaking, the muscles of the face. An innocent, amiable, and virtuous young lady, of high birth, who had been educated in the retirement of the country, happened one evening to pass a mirror, immediately after having attended evening prayers, and with a candle in her hand was depositing a bible on a table, when she observed her image reflected in the glass: affected with a sense of humility, and of extreme modesty, she averted her eyes and retired. A succeeding winter was passed in the amusements and dissipation of a city, where this lady had the misfortune to forget all her previously devout pursuits: but returning to the country, she once more passed the glass and the bible, and saw her features reflected, now deprived of those fascinating graces which belong alone to the serene and happy state of mind she had lost. Alarmed at the change, she fled from the spot, and retiring to a sofa, ejaculated sentences of penitence, and formed resolutions of future amendment.

Lavater begins his remarks on the human face with the forehead. According to this observer, the general form, proportion, the arch obliquity, and position of the skull of the forehead, denote the degree of thought, the sensibility, the mental vigour, and the propensities of man; and at the same time the skin of this part of the head explains, by its hue, tension, or wrinkles, the state of the mind at the moment of observation, and the passions which influence it, the bones affording the internal quantity, and the covering the application of power: however the latter may be affected, it is well known that the bones must remain unaltered, and yet they regulate the wrinkles by their variation of component form. Wrinkles are produced by a certain degree of flatness; others arise from arching, and these considered separately will give the form of the arch, and *vice versa*. Some foreheads are furnished with wrinkles that are confined to horizontal, perpendicular, curved, and others confused and mixed lines; those least perplexed when in action are usually observed in foreheads without angles.

Lavater appears to have been the first who attended to the peculiar turns of the position and outline of the forehead, which he considered the most important part presented for the study of the physiognomist. This he divides into three classes, and those he termed the perpendicular, the projecting, and the retreating, each possessing a number of variations: the principal, however, are rectilinear, "half round, half rectilinear, flowing into each other; half round, half rectilinear, interrupted; curve-lined, simple; the curve lined double and triple."

A long forehead denotes much capacity of comprehension, and less activity; a compressed, short, and firm forehead, more compression, stability, and little volatility; severity and pertinacity belong to the rectilinear; and the more curved than angular portends flexibility and tenderness of character; deficiency of understanding is discoverable in those whose foreheads are perpendicular from the hair to the eye-brows; but the perfectly perpendicular, gently arched

at the top, signifies that the possessor thinks coolly and profoundly. The projecting forehead indicates stupidity and mental weakness; the retreating, exactly the reverse; the circular, and prominent above, with straight lines below, and nearly perpendicular, shews sensibility, ardour, and good understanding; the rectilinear oblique forehead has the same properties; arched foreheads are considered as feminine; an union of curved and straight lines, happily disposed, with a similar position of the forehead, gives the character of consummate wisdom. "Right lines, considered as such, and curves, considered as such, are relaxed, as power and weakness, obstinacy and flexibility, understanding and sensation." When the bones surrounding the eye project, and are sharp, the person thus formed possesses a powerful stimulus to exercise a strong mental energy, which is productive of excellent and well digested plans, and yet this doth not seem a peculiar mark of wisdom, as many wise men have been known without it: those thus circumstanced have more firmness, when the forehead rests perpendicularly upon horizontal eye-brows, and is considerably rounded towards the temples. Perpendicular foreheads, which, however, project so as not to rest on the nose, and which are short, small, fine, and are full of wrinkles, give undoubted indications of a weakness of the thinking faculties; perseverance and oppressive violent activity, united with vigour and harshness, belong to the forehead composed of various confused protuberances; and on the other hand, when the profile of this part of the head affords two well proportioned arches, the lowest projecting, it is a certain sign of a good temperament and a sound understanding. All great and excellent men have been found to have their eye-bones firmly arched, and well defined; and circumspection, followed by stability, attends square foreheads, with spacious temples, and eye-bones of the above description; when perpendicular natural wrinkles appear, they express power of mind and application; but horizontal, interrupted in the middle, or broken at the extremities, betray, in general, negligence, if not want of ability.

Deep indenting in the bones of the forehead situated between the eye-brows, and extending in a perpendicular direction, mark the happy few who possess generous and noble minds, connected with excellence of understanding; besides, a blue vena frontalis, in the form of a Y, situated in an arched smooth forehead, is an indication of similar advantages. Lavater having given the above hints, describes the following characteristics, which he asserts, give "the indubitable signs of an excellent, a perfectly beautiful and significant, intelligent, and noble forehead." Such must be one-third of the face in length, or that of the nose, and from the nose to the chin; the upper part must be oval, in the manner of the great men of England, or nearly square; the skin must be smooth, and wrinkled only when the mind is roused to just indignation, or deeply immersed in thought, and during the paroxysm of pain; the upper part must recede, and the lower project; the eye-bones must be horizontal, and present a perfect curve upon being observed from above; an intersecting cavity should divide the forehead into four distinct parts, but with that slight effect as to be only visible with a clear descending light; and all the outlines should be composed of such, that if the section of one-third only is observed, it would be difficult to decide whether they were circular or straight; to conclude this portrait of a transcendent forehead, the skin must be more transparent, and of a finer tint than the remainder of the face. Should an infant, a relative, or a friend, who possesses a forehead resembling the above description, seriously err, the good enthusiast intreats, that the corrector may not despair of success,

PHYSIOGNOMY.

cess, as in all human probability the latent seeds of virtue may be roused into growth by perseverance, and finally produce the desired fruit.

The eyes of mankind are composed of various shades of colour, the most common of which are grey mixed with white, grey tinged with blue, and shades of green, orange, and yellow. According to Buffon, the orange and blue are most predominant, and those colours often meet in the same eye; those generally supposed to be black are not really so, and may be found, on attentive examination, and with a proper disposition of the light, to consist of yellow, a deep orange, or brown, which being violently opposed to the clear white of the ball, assumes a darkness mistaken for black. The same naturalist observes, that shades of yellow, orange, blue and grey, are visible in the same eye; and when blue, even of the lightest tint, appears, it is invariably the predominant colour, and may be found in rays dispersed throughout the iris: the orange is differently disposed, at a trifling distance from the pupil, is in flakes, and round; but the blue so far overpowers it, that the eye assumes the appearance of being wholly of that colour. The fire and vivacity emitted by the eye cannot be so powerful in those of the lighter tints; it is therefore in the dark ones alone that we look for the emotions of the soul; quiet and mildness, and a certain degree of archness, are the characteristics of the blue. Some eyes are remarkable for the absence of colour; the iris is faintly shaded with blue or grey, and the tints of orange are so light, that they are hardly observable: in eyes thus constituted, the black of the pupil appears too conspicuous, and it may be said, that portion is alone visible at a little distance, which circumstance gives the person a ghastly and spiritless appearance.

There are eyes whose iris may be said to be almost green; but these are very uncommon. It would require the pen of an inspired writer to describe the astonishing variety of expression of which the eyes are capable: being situated near the supposed seat of the soul, every sensation of that invisible spirit appears to rush in full vigour from those intelligent organs: all the passions may be seen in them; we shrink from their indications of anger, we find pleasure with all her train of joys dancing in them, we feel their force in love, and melt into tears upon observing them suffused with the moisture of grief; in short, their language is far more powerful than that of the tongue. The transitions are so rapid in the expression of the eyes, that it requires very close and attentive examination to catch and describe the emotions of the mind visible in them; admitting this fact, it will appear that the physiognomist is liable to numerous and egregious errors in drawing his conclusion of propensities from them. Paracelsus, a man of strong genius, and, like Lavater, misguided in many instances by enthusiasm, and a kind of superstition allied to the study of this art or science, pronounced that those eyes generally termed black frequently denoted health, firmness, courage, and honour; but the grey, deceit and instability. Thus far probability at least accompanies his remarks. It is, however, impossible to subscribe to his assertion, that short-sighted persons are deceitful and crafty, or that those who squint have similar propensities to evil, as it is evident both the peculiarities alluded to are the consequences of injury, and are never found in people whose organs of vision are perfect: indeed many instances might be cited of the actual and known cause of squinting and near sight, which frequently occur in adults from extreme anxiety and disease.

Small eyes situated deep in the sockets are said, by Paracelsus, to indicate active wickedness, with a mind calculated

to oppose with vigour, and suffer with perseverance; and their opposites, or very large prominent eyes, he conceived, explained the avaricious, covetous, propensities of their possessor; those in constant motion denote fear and care; winking is the mark of foresight, of an amorous disposition, and quickness in projecting; and the eye fearful of looking directly forward, decides upon innate modesty.

Lavater thought blue eyes, in general, signified effeminacy and weakness, and yet he acknowledged that many eminent men have had blue eyes; still he was convinced that strength and manhood more particularly belong to the brown: in opposition to this opinion, the Chinese, who are known to be an imbecile people, rarely have blue eyes; these contradictions, it must be confessed, weaken the reliance we are inclined to place on appearances during the quietest state of the eyes, and the indications of their colour. Men intemperate in anger, and easily irritated, may be found with eyes of all the usual colours; when they incline to green, ardour, spirit, and courage, are constant attendants. People of a phlegmatic habit, but who may be roused to activity, have clear blue eyes, which never belong to those inclined to melancholy, and they rarely belong to the choleric. Benevolence, tenderness, timidity, and weakness, are exhibited by the perfectly semi-circular arch formed by the under part of the upper eye-lid; persons of acute and solid understandings have a generous open eye, composing a long and acute angle with the nose; and when the eye-lid forms a horizontal line over the pupil, it is a strong indication that he who possesses it is subtle, able, and penetrating. Widely opening lids, shewing the white of the ball under the other colours, may be observed in the phlegmatic and timid, as well as in the courageous and rash; but upon comparing these marks in the different characters just mentioned, a very perceptible difference is discovered in the characteristics of the eyes; the latter are less oblique, better shaped, and more firm.

The eye-brows are essential in the expression of the eyes; in anger they are brought down and contracted; in all pleasant sensations, and in astonishment, they assume a fine arch; in youth they are naturally and regularly arched; the horizontal and rectilinear eye-brows belong to the masculine bias of the soul; and the above designations combined shew strength of understanding, united with feminine kindness; those that are deranged in their appearance, and the hairs growing in various directions, demonstrate a wild and perplexed state of mind; but if the hair is fine and soft, they signify gentle ardour. The compressed firm eye-brow, formed of parallel hairs, is a certain proof of profound wisdom, true perception, and a manly, firm habit of thought. There are eye-brows which meet across the nose; this circumstance gives the person an air of ferocious gloom, which is admired by the Arabs, but the ancients, versed in physiognomy, conceived such to be the characteristic of cunning; Lavater, on the contrary, observes, that he had discovered them on the most worthy and open countenances, admitting at the same time that they may denote a heart ill at ease. Those who think profoundly, and those equally prudent and firm in their conduct, never have high and weak eye-brows, in some measure equally dividing the forehead; they rather betray debility and apathy, and though men of an opposite character may be found with them, they invariably signify a diminution of the powers of the mind. Thick angular eye-brows, interrupted in their lengths, signify spirit and activity; and when they approach the eyes closely, the more firm, vigorous, and decided, is the character; the reverse shews a volatile and less enterprising disposition; when the extremes are remote from each other, the sensations of the possessor

PHYSIOGNOMY.

are sudden and violent. White eye-brows are demonstrative of weakness, in the same degree that the dark brown are of firmness.

The good Lavater considered the nose as the abutment, or buttress, of the forehead, the seat of the brain, without which the whole face would present a miserable appearance; indeed an ugly or disagreeable set of features is never accompanied by a handsome nose: but there are thousands of fine and expressive eyes where a perfectly formed nose is wanting: he describes this portion of the face as requiring the following peculiarities: "Its length should equal the length of the forehead; at the top should be a gentle indenting; viewed in front, the back should be broad, and nearly parallel, yet above the centre something broader; the bottom, or end of the nose, must be neither hard nor fleshy, and its under outline must be remarkably definite, well delineated, neither pointed nor very broad; the sides, seen in front, must be well defined, and the descending nostrils gently shortened; viewed in profile, the bottom of the nose should not have more than one-third of its length; the nostrils above must be pointed below, round, and have in general a gentle curve, and be divided into equal parts by the profile of the upper lip; the side, or arch of the nose, must be a kind of oval; above, it must close well with the arch of the eye-bone, and near the eye must be at least half an inch in breadth. Such a nose is of more worth than a kingdom." Numbers of great and excellent men have flourished in all ages of the world, whose noses would suffer essentially by a comparison with Lavater's description of a nose, more valuable to the possessor than extensive empire: indeed, he is compelled to acknowledge this indisputable fact, and observes that he has seen persons endowed with purity of mind, noble in their conceptions, and capable of exertion, whose noses were small, and the arches of their profiles inverted; and yet true to his first principles, he discovered, or imagined he discovered, their worth to consist chiefly in the elegant effusions of their imaginations, their learning, or fortitude in suffering, and this is accompanied with a proviso that the remainder of their form must be correctly organized.

Noses arched near the forehead belong to those who possess the energy to command, are capable of ruling, acting, overcoming, and destroying; others, rectilinear, are the medium between the extremes above noticed, and are appropriated by nature to persons who act and suffer with equal power and patience. Socrates, Laireffe, and Boerhaave, were great men, and had ill-shaped noses, and were distinguished for meekness and gentleness. Were it possible to attribute a general prevalence of disposition to a general form of the nose, individuals of every nation would be found to resemble the Tartars, who have flat indented noses, the Negroes who have broad, and the Jews who have high arched noses, in their propensities, and it must follow that whatever qualities the physiognomist may apply to those individuals, must also belong to the whole people whose noses bear a resemblance to them; were this particular accurately examined into, it would tend, in a great measure, to confirm the correctness or incorrectness of the science, as it has hitherto been practised.

The admirers of this study attribute great powers to the mouth, in expressing the emotions of the mind; and Lavater expatiates on it with enthusiastic fervour indeed: "Whoever," he exclaims, "internally feels the worth of this member, so different from every other member, so inseparable, so not to be defined, so simple, yet so various; whoever, I say, knows and feels this worth, will speak and act with divine wisdom." He then proceeds to call it "the chief seat

of wisdom and folly, power and debility, virtue and vice, beauty and deformity, of the human mind; the seat of all love, all hatred, all sincerity, all falsehood, all humility, all pride, all dissimulation, and all truth." Granting the benevolent pastor full assent to these observations on the mouth, it becomes the indispensable duty of all men to notice the physiognomy, or indications of that organ; in making those observations, it will be necessary to examine the lips separately, and to ascertain when they are closed, during the moments of perfect tranquillity, whether that operation is performed without a forcible exertion of the muscles, particularly the middle of the upper and under lips, the bottom of the middle line at each end; and finally, the extending of the middle line on both sides.

The character of the man is proclaimed in the lips, the more firm the latter the more fixed the former; the weak and irresolute man has weak lips, with rapidity in their motion. The vicious, cringing, mean, and bad countenance is never formed with lips well defined, large, and justly proportioned to the other parts of the face, and the line of which is equally serpentine on each side; such, though they may denote a tendency to sensuality, belong exclusively to a character deserving of admiration in most relations of life.

A mouth, the lips of which are so thin as to present, at first view, little more than a line, is said to indicate apathy and quiet, but industrious when roused. When this description of mouth is raised at the extremities, vanity or vain pretensions, affectation, and probably deliberate malice, distinguish those so formed. The opposite of this kind of lips, swelled into considerable size, is a mark of indolence and sensuality. The "cut through, sharp drawn lip," as Lavater terms some, has to contend with avarice and anxiety. Lips closed accurately, without exertion, and handsome in their outline, belong to the exercise of discretion and firmness. Lips with the latter advantage, and the upper projecting, is generally appropriated to the virtuous and benevolent, though there are, without doubt, numberless persons of excellent character whose under lips project, but in Lavater's opinion, the last peculiarity implies a well-meaning man, whose goodness consists rather of cold fidelity than ardent friendship. The under lip, hollowed in the middle, denotes a fanciful character. Let the moment be remarked, when the conceit of the jocular man descends to the lip, and it will be seen to be a little hollow in the middle.

The mouth remaining naturally closed, invariably signifies fortitude and courage. When the latter quality is in operation, the mouth closes insensibly; the naturally open mouth makes a disposition to complain; the closed, on the contrary, designates endurance. "Though physiognomists," adds Lavater, "have as yet but little noticed, yet much might be said concerning the lips improper, or the fleshy covering of the upper teeth, on which anatomists have not, to my knowledge, yet bestowed any name, and which may be called the curtain, or pallium, extending from the beginning of the nose to the red upper lip proper. If the upper lip improper be long, the proper is always short; if it be short and hollow, the proper will be large and curved:—another certain demonstration of the conformity of the human countenance. Hollow upper lips are much less common than flat and perpendicular; the character they denote is equally uncommon."

The ancients who studied the physiognomy of man, supposed that diminutive short teeth betrayed the weakness of those who possessed them; more modern observers contradict this supposition, and declare that men of uncommon strength have such, but they are rarely of that pure white so necessary

to preserve the general beauty of the countenance. Teeth of unusual length, and narrow, are signs of weakness and cowardice; those justly proportioned to each other, white and transparent, which appear immediately upon opening of the mouth, though not projecting, and entirely exposed to view, from the insertion in the gums to the opposite extremities, are seldom to be met with in the jaws of persons who possess unamiable propensities; when teeth of a different description are discovered belonging to amiable and worthy characters, enquiry will generally satisfy the physiognomist that his conclusions on this head were just, and that the blackness and derangement were occasioned by disease.

In one way the observer and admirer of this art cannot possibly be mistaken, for he that neglects his teeth, suffering them to decay through contempt of public opinion and indolence, may be safely pronounced an unhappy character, with many evil propensities.

The chin alone remains to be noticed in this slight survey of the human face, as connected with the internal operations of the soul or mind. The projecting chin is said to mark something decided, and the receding the reverse; and it has been asserted that the presence or absence of strength is frequently demonstrated by the form of this part of the countenance; it has also been remarked, that sudden indentings in the midst of the chin are peculiar to men of excellent cool understandings, unless attended by marks of a contrary tendency. When the chin is pointed, those so formed are supposed to be penetrating and cunning, though it seems there are people with pointed chins who are different at least in the latter particular; and here again the chin offers a certain criterion for the physiognomist, who may securely pronounce a large fat double chin an appendage of gluttony. "Flatness of chin speaks the cold and dry; smallness, fear; and roundness, with a dimple, benevolence."

"No one," says Lavater, "whose person is not well formed can become a good physiognomist. Those painters were the best whose persons were the handsomest. Reubens, Vandyke, and Raphael, possessing three gradations of beauty, possessed three gradations of the genius of painting. The physiognomists of the greatest symmetry are the best. As the most virtuous can best determine on virtue, so can the most handsome countenances on the goodness, beauty, and noble traits of the human countenance, and consequently on its defects and ignoble properties. The scarcity of human beauty is the reason why physiognomy is so much desired, and finds so many opponents. No person, therefore, ought to enter the sanctuary of physiognomy, who has a debased mind, an ill-formed forehead, a blinking eye, or a distorted mouth. "The light of the body is the eye; if, therefore, thine eye be single, thy whole body shall be full of light! but if thine eye be evil, thy whole body shall be full of darkness: if therefore the light that is in thee be darkness, how great is that darkness?"

PHYSIOLOGI, in *Botany*, those authors whose writings tend to set that study in its clearest light, by explicating and enumerating the various dispositions of the male and female parts in the flowers of plants.

PHYSIOLOGY, *Φυσιολογια*, formed of *φύσις*, *nature*, and *λογος*, *discourse*, or *reason*, the doctrine of nature, or natural bodies; called also *physics*, and *natural philosophy*.

PHYSIOLOGY properly denotes only an internal reasoning, or discoursing, which stops or terminates in the speculation, or abstract contemplation of its object, *viz.* natural appearances, their causes, &c. and does not direct or prescribe rules for the making of natural things, *e. gr.* stones, plants, &c.

In which view, chemistry does not properly belong to physiology, but is a kind of counter part thereto, as in many cases, imitating nature, rather than considering and explaining her.

PHYSIOLOGY, according to its etymological import, signifies a discourse on nature; but it is now usually employed, in a more limited sense, to denote the science which treats of the powers that actuate the component parts of living animal bodies, and of the functions which those bodies execute. It presupposes therefore a knowledge of the structure of the body, which is the object of anatomy; the latter is conversant with the dead, the former with the living body; the one may be called the science of organization, the other the science of life.

The principal source of our physiological knowledge of the human body, is an observation of its actions in all the various states comprehended under the general terms of health and disease. The results of the latter are very instructive: comparison of the phenomena during life with the state of parts after death, shews us the uses of many organs, which cannot be submitted to direct observation in the living state. But the information derived, even from the most attentive survey of the living human being in health and disease, is still very imperfect: it leaves many interesting subjects entirely unexplained: the viscera are all so hidden by their situation, that we can hardly have the testimony of our senses for any of their functions in man. The physiologist supplies this deficiency by experiments on living animals, in whom he exposes the various internal organs, and observes the consequences of circumstances altered and combined at his pleasure. It is not our business to consider here, whether this use of sentient beings is morally justifiable; or whether it may be advantageous to the individual or society, to stifle that internal voice which remonstrates most loudly in every mind not accustomed to acts of cruelty, against the infliction of pain on beings who seem to feel it as acutely as ourselves: we have only to observe that these proceedings, however afflicting to the humane, are full of physiological instruction. A comparison of the structure and functions of animals in all classes of the animal kingdom, is another most important source of physiological knowledge. The aid of chemistry is indispensable to the physiologist in the subjects of respiration, perspiration, and the secretions; indeed in unfolding the structure of the body in general.

We must refer the reader to various articles of this Cyclopædia, for an account of the physiology of man. Under **LIFE** and **FIBRE** he will find general views of the structure and actions of the body; and under **FUNCTION**, a classification of the functions. The physiology of the thoracic organs will be found under **HEART**, **CIRCULATION**, **LUNGS**, and **RESPIRATION**; of the lymphatic system, under **ABSORBENTS** and **ABSORPTION**; of the blood-vessels, under **HEART** and **ARTERY**; of the brain, nerves, and muscles, under **BRAIN**, **NERVOUS System**, and **MUSCLE**; of the mechanical preparation of the food, and its descent into the stomach, under **DEGLUTITION**; of the changes wrought on it in the alimentary canal, under **DIGESTION**. Further remarks on subjects connected with this will be found under **LIVER**, **SPLEEN**, **PANCREAS**, **STOMACH**, and **INTESTINES**. The physiology of the urinary apparatus is considered under **KIDNEY**. The functions of the organs of sense are explained under **INTEGUMENTS**, **EYE**, **EAR**, **NOSE**, and **TONGUE**; and those of the generative organs, under **GENERATION** and **EMBRYO**. Various physiological points are considered under **GLAND**, **LARYNX**, **MEMBRANE**, and **DEATH**; also under the article **MAN**. We may also refer

to BONE, CARTILAGE, CELLULAR Substance, CRANIUM, and other anatomical articles.

The Institutiones Physiologicæ of Blumenbach is the best compendium of this science: it is executed with brevity and great neatness, and is remarkable for the small quantity of objectionable matter it contains. Its well selected references will lead the student to the best sources of more detailed information. The First Lines of Haller, and the Elements of Physiology of Richerand, are inferior to the above-mentioned classical production of Blumenbach. The Elementa Physiologicæ of Haller is a most accurate and useful repository of all the facts and opinions relating to physiological science up to the period of its publication, and supercedes the necessity of all works previous to that date. The works of John Hunter and of Bichat (his Anatomie Generale, and Recherches sur la Vie et la Mort), the System of Physiology of Dumas, the Leçons d'Anatomie comparée of Cuvier, and the Manual of the same science of Blumenbach, with various detached papers in the collections of learned societies in this and foreign countries, are the best sources of information subsequent to the work of Haller. More particular references will be found in the different articles.

PHYSKIUM, in Botany, φυσικιον, a little bladder, is a genus of Loureiro's, found in the waters of Cochinchina, which by his characters and description appears to be very near the *Valisneria oëandra*, Roxb. Coromand. v. 2. 34. t. 165, and probably may be the very same plant.

PHYSOCELE, from φυσω, flatus, and κλη, a tumour, in Surgery, a swelling occasioned by air. See EMPHYSEMA.

PHYSOMETRA, in Medicine, from φυσω, to inflate, and μετρα, the womb, a tympany of the womb, occasioned by air distending that organ. This is, at all events, a very rare disease, and the accounts given of it by the older authors have probably originated in mistake. Air, however, appears to be occasionally generated in the internal cavities of the living body, as Mr. John Hunter suggested, by a sort of secretion from the blood-vessels. Sauvages mentions two varieties of the disease. Nofol. Method. Clafs x. Gen. 14.

PHYSOSPERMUM, in Botany, from φυσω, to inflate, and σπερμα, seed, a genus so named by Cusson, who removed it from LIGUSTICUM, (see that article,) principally on account of the double skin of the seed, the outer coat being separated by a small cavity from the inner. The plant, on which this supposed genus depends, is no other than the so much talked of, and long so little known, *L. cornubiense* of Linnæus and Fl. Brit. the *L. alterum*, Lob. Ic. 786; see Juss. Gen. 222.

PHYSSOPHORA, in Natural History, a genus of the class and order Vermes Mollusca. The generic character is this; body gelatinous, pendent from an aerial vesicle, with gelatinous sessile members at the sides, and numerous tentacula beneath. There are three species. They are all nearly allied to the Medusæ, and might perhaps without much impropriety be removed to that genus.

Species.

HYDROSTATICA. Oval; with numerous, lateral, three-lobed vesicles, open outwardly; middle intestine and four larger tentacula red. It inhabits the Mediterranean; is about half an inch long, compressed, and always swims with the tip of the vesicle above the water.

ROSACEA. Orbicular, and imbricate with oblong, horizontal, foliaceous membranes affixed to the vesicle. It is found in the Mediterranean. The body is hyaline, an inch

in diameter, and resembles a full blown flower bending downwards. The vesicle is obtuse, ovate, reddish, and covered with flat, obtuse, foliaceous membranes, curved and thickly laid.

FILIFORMIS. Lateral members oblong, filiform, and pendent. This is found in the Mediterranean. The body is very tender, not thicker than a thread, and a span long, hyaline, with an obtuse ovate head, about the size of a grain of rice.

PHYSTA, in Ichthyology, a name given by Gesner, and some others, to the fish called by the Greeks, and many of the later authors, *ballerus* and *balerus*. Artedi denies its right to any generic name, reducing it to the genus of the cyprini, to which it evidently belongs, and distinguishing it from the others of that numerous genus by the specific name of the very broad and thin cyprinus, with forty rays in the pinna ani. See CYPRINUS.

PHYSTE, in the Writings of the Ancient Physicians, a word used to express a mass of meal macerated in a close vessel with wine, but not left to ferment.

PHYTALIA, a word used by the ancients in two very different senses; with some expressing the latter part of the winter season, and with others a place where vines are planted, whether in standard vineyards or otherwise.

PHYTEUMA, in Botany, a name adopted from Dioscorides, whose φυτευμα, whatever it may have been, appears to have received that appellation from φυτεω, to sow or plant. Some have supposed an allusion to the reputed qualities of the herb as a philter, which Dioscorides and Pliny mention. We can trace no reason for the Linnæan application of the name, except perhaps in the fissures or perforations of the fruit of our *Phyteuma*, to which the Greek description seems to allude. Linn. Gen. 89. Schreb. 118. Willd. Sp. Pl. v. 1. 919. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 354. Sm. Fl. Brit. 240. Prodr. Fl. Græc. Sibth. v. 1. 143. Juss. 165. Lamarck Illustr. t. 124. Gærtn. t. 30.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, in five deep, acute, somewhat spreading segments. Cor. of one petal, wheel-shaped, spreading, in five deep, linear, acute, recurved segments. Stam. Filaments five, shorter than the corolla; anthers oblong. Pist. Germen inferior, roundish; style thread-shaped, the length of the corolla, recurved; stigma in two or three oblong revolute segments. Peric. Capsule roundish, membranous, of two or three cells, opening by a fissure at each side. Seeds very numerous, small, roundish, smooth.

Ess. Ch. Corolla wheel-shaped, in five deep linear segments. Stigma in two or three segments. Capsule inferior, opening laterally, of two or three cells.

A genus of herbaceous, almost uniformly perennial, mountain or alpine, European plants, with handsome blue flowers; nearly allied to *Campanula*, but with a differently shaped corolla. Willdenow well remarks, that the alpine species, and indeed all that are the produce of the more northern or middle regions of Europe, bear a dense oblong spike, or roundish head; while the oriental ones generally have dispersed flowers. In sensible qualities the genus agrees with *Campanula*; and the herbage, when wounded, discharges a bitter milky fluid. Linnæus has six species in his Sp. Pl. and the same number in Syst. Veg. ed. 14. Willdenow has sixteen. One only is wild in Britain. Five exotic species occur in Hort. Kew. one of them before published by Dr. Sims alone. Three are added to the stock in Prodr. Fl. Græcæ, of which one is *Campanula limonifolia* of Linnæus and Willdenow. The alpine species are,

PHYTEUMA.

are, in many instances; not free from obscurity in their characters and synonyms, as being liable to vary much, according to shade or exposure of situation, in the shape of their leaves, length and figure of their spikes, as well as in their whole habit and dimensions. Hence arises so much obscurity in their determination, that though we have examined not a few in their native stations, and have received some authentic specimens from the authors, who have described them, the difficulty of arranging their synonyms, and defining their limits, seems rather to grow under our hands. We shall attempt to correct some errors, in enumerating a few of the most certain species. There can be no good reason for persevering in the old blunder of making *Phyteuma* of the feminine gender.

Ph. Scheuchzeri. Willd. n. 2. Allion. Pedem. v. 1. 116. t. 39. f. 2. (*Rapunculus*, n. 682; Hall. Hist. v. 1. 304.)—Flowers in a round head, much exceeded by the long, linear, spreading bractæas. Stem leafy. Leaves linear-lanceolate, toothed, stalked, rough-edged.—Native of the alps of Switzerland and Savoy.—Stem from twelve to eighteen inches high, upright, weak, slender, smooth, simple. Leaves from one to three inches long, scattered, narrow, bluntish, minutely rough at the edges, and beset with glandular distant teeth. Flowers not very numerous, in a perfectly round, solitary, terminal head. Bractæas few, one much longer, and more leafy, than the rest. Style slender, hairy upwards. Style long, three-cleft, revolute.

Ph. scorzonifolium. Villars Dauph. v. 1. 519. t. 12. f. 2.—Spike cylindrical. Bractæas short, reflexed. Stem naked above. Leaves linear-lanceolate, toothed, smooth.—Native of the mountains of Dauphiny and Italy. We gathered it on the hill called *la Bocchetta*, above Genoa, in 1787. Willdenow considers this as but a variety of the former, to which he was perhaps led by an assertion of Villars, that it was sent by Allioni as his *Ph. Scheuchzeri*. Here must have been some mistake. The two species are essentially distinct in their inflorescence, and all the rest of the characters indicated above. The spike in our Genoese specimens is in seed, and measures near two inches in length, though only a quarter of an inch in thickness. The stem-leaves are mostly sessile, quite smooth at the edges, numerous about the lower part of the stem, though wanting in the upper. Their teeth are more like ferratures.

Ph. hemisphericum. Grafs-leaved Rampion. Linn. Sp. Pl. 241. Willd. n. 4. Ait. n. 1. Jacq. Ic. Rar. t. 333.—Head roundish. Bractæas ovate, pointed. Leaves linear, nearly entire, about as long as the stem.—Native of the alps of Switzerland, Italy, France, and Germany, as well as of the Pyrenees. It has been introduced from time to time into our gardens, but requires the shelter of a frame, like many other alpine productions, that are so long buried in snow in their native stations. The roots are somewhat creeping. Stems from two to six inches high, ascending or curved, concealed by the numerous, chiefly radical, narrow, smooth leaves, which sometimes overtop them, and whose grassy aspect characterises this species. The bractæas are several, shorter than the head, broad, taper-pointed, somewhat membranous, fringed. Two or three of the very earliest leaves are often short and spatulate.

Ph. comosum. Glaucous Rampion. Linn. Sp. Pl. 242. Willd. n. 5. Ait. n. 2. Jacq. Auftr. append. 56. t. 50.—Flowers in a terminal leafy tuft. Leaves strongly toothed, smooth, glaucous; the radical ones heart-shaped.—This beautiful species, so remarkable for its very glaucous herbage, and purple inflated flowers, was first found on mount Baldus. It occurs also on the alps of Carniola and the

Tyrol, but scarcely elsewhere. The stem is but three or four inches high. Leaves broad, mostly elliptical. No obscurity attends this plant, of which many figures are to be found in the old authors. We have never seen a garden specimen. The root is biennial.

Ph. orbiculare. Round-headed Rampion. Linn. Sp. Pl. 242. Willd. n. 6. Ait. n. 3. Jacq. Auftr. t. 437. Engl. Bot. t. 142.—Head roundish. Leaves crenate; the lowest somewhat heart-shaped; the uppermost sessile, ovate, pointed.—Found on the mountains of Italy and Switzerland, as well as on the chalky hills of Suffex and Surry, being the only British species. It flowers in August, and is perennial. The first or lowest leaves only are heart-shaped; the rest of the radical ones elliptic-oblong; all crenate, veiny, slightly roughish: the stem-leaves are scattered, sessile, small, lanceolate or ovate, taper-pointed. Stem about a foot high, in luxuriant ground twice as much, crowned with a dense head of numerous dark-blue flowers, subtended by several ovate fringed bractæas.—Willdenow subjoins as varieties three species of Villars, which we can scarcely think belong to *orbiculare*, though we have not had an opportunity of seeing more than two of them. *Ph. lanceolatum*, Villars t. 12. f. 1, we have not seen, but the uniformly ovate leaves, all stalked, indicate a strong specific difference from our *orbiculare*. *Ph. ellipticum*, t. 11. f. 2, is still more different, in its short dense hairiness, as well as in its oblong blunt upper leaves, and long leafy bractæas. *Ph. Charmelii*, t. 11. f. 3, is abundantly distinct from all these, in its small, violet-like, heart-shaped, radical leaves, rough with minute points, and supported by capillary footstalks, above five times their own length; as well as in its humble stem, bearing many long, narrow, lanceolate or linear leaves, and the long narrow bractæas which accompany its small dense head of flowers.

Ph. repandum. Olympian Rampion. Sm. Prodr. Fl. Græc. Sibth. v. 1. 143.—Spike rather lax. Leaves elliptic-oblong, stalked, wavy, smooth. Stem perfectly simple, almost leafless.—Gathered by Dr. Sibthorp on the summit of the Bithynian Olympus. The root is strong, woody, and perennial, producing many tufts of leaves not unlike those of *Globularia nudicaulis*, but less coriaceous, and somewhat wavy at the margin. Stems solitary, erect, straight, two, three, or four inches high, smooth, bearing one or two distant leaves. The footstalks are all fringed at the base. Flowers blue, in a solitary, erect, lax spike, the lower ones often in pairs, and sometimes very remote. Bractæas linear-lanceolate, fringed. This species is no where figured.

Ph. ellipticum. Elliptical Mountain Rampion. Sm. Prodr. Fl. Græc. Sibth. v. 1. 143. Fl. Græc. t. 217. unpubl. (*Ph. campanuloides*; Sims in Curt. Mag. t. 1015. Ait. n. 5.)—Spike rather lax. Leaves elliptical, stalked, crenate, rough. Stem perfectly simple, leafy, hairy.—Native of the Bithynian Olympus and of mount Caucasus. The root is somewhat creeping. Stems in the wild plant, from six to twelve inches high, erect, more or less rough with hoary dense hairs, and bearing many elliptic or ovate, strongly crenate, roughish leaves, about an inch and a half long, on fringed footstalks of various lengths. Flowers deep blue, in a terminal bracteated spike, extremely variable in length and luxuriance. In a garden, it seems, the stem becomes smooth, and the spike racemose, with ternate flowers, which last character occasionally presents itself likewise in wild specimens. Dr. Sibthorp's figure, with about seven flowers, and that in the Botanical Magazine, exhibit the two extremes of the inflorescence. Our specimens account for the appellation of *canescens*, under which Mr. Loddiges received the plant; and it is much to be wished that our

specific name, antecedent to that in the Magazine, might also take place of the probably unpublished Flora Taurica, *campanuloides* being liable to several objections.

Ph. betonicifolium, Villars Dauph. v. 2. 518. t. 12. f. 3; *spicatum*, Linn. Sp. Pl. 242. Fl. Dan. t. 362; and *ovatum*, Willd. n. 10, which last is Haller's *Rapunculus* n. 683, are sufficiently defined in Willdenow, nor does any obscurity attend these species.

Ph. limonifolium. Sea-lavender Rampion. Sm. Prodr. Fl. Græc. Sibth. v. 1. 144. Fl. Græc. t. 218, unpubl. (*Campanula limonifolia*; Linn. Sp. Pl. 239. Willd. Sp. Pl. v. 1. 914. *C. orientalis*, *limonii* *minimi* *facie*, *flore* *patulo*; Tourn. Cor. 3.)—Leaves lanceolate, roughish with reversed hairs, wavy, and somewhat toothed. Stem panicled. Flowers sessile, about three together.—Gathered by Tournefort in the Levant; by Sibthorp in grassy places towards the summit of the Bithynian Olympus. The root is very thick and woody, crowned with numerous tufts of narrow, bluntish, long-stalked, spreading leaves, about three inches long, and half an inch wide, of a bright green; their short rigid pubescence directed backwards, or towards the base; their margin either toothed or waved. Stems about a foot high, erect, round, smooth, leafy, copiously branched in an alternate manner; their branches spreading, leafless, beset with many smallish, blue, sessile flowers, two or three together, having yellow anthers, and a rough, reddish, club-shaped style.

Ph. lebelioides. Willd. n. 12. Phytogr. fasc. 1. 6. t. 4. f. 2. (*Rapunculus orientalis*, *hesperidis* *folio*; Tourn. Cor. 4.)—Leaves linear-lanceolate, somewhat toothed, rough. Stem panicled. Flowers stalked, scattered.—Gathered by Tournefort in America. It is very remarkable that so great a *corollifol* should have separated this plant generically from the last, their flowers agreeing so exactly in the depth of their segments. Indeed they come so near in specific characters, that but for the different distributions of their flowers, which seems constant, we could hardly have distinguished them.

Ph. amplexicaule. Toothed Rampion Willd. n. 15. Sm. Fl. Græc. Sibth. t. 219, unpubl. (*Rapunculus orientalis*, *campanule* *pratensis* *folio*; Tourn. Cor. 4.)—Leaves ovate, pointed, strongly and doubly serrated, smooth; slightly heart-shaped, and clasping the stem. Cluster leafy, somewhat panicled.—Gathered by Dr. Sibthorp, in grassy spots, near the top of the Bithynian Olympus. A very handsome species, twelve or eighteen inches high, smooth and unbranched, with numerous, alternate, strongly and sharply serrated, or toothed, leaves, about two inches long. Flowers large, bright blue, vying in beauty with the following, but far less numerous.

Ph. pinnatum. Winged-leaved Rampion. Linn. Sp. Pl. 242. Willd. n. 16. Ait. n. 6. Venten. Jard. de Cels. t. 52. Sm. Fl. Græc. Sibth. t. 220, unpubl. (*Rapunculus creticus*, *feu* *Pyramidalis* *altera*; Tourn. Inf. 113. *Petro-marula* *di* *Candia*, *overo* *lattuca* *petrea*; Pon. Bald. 96. *Imperati* *Hist.* Nat. 668.)—Leaves pinnate. Panicle cylindrical, branched, many-flowered.—Very common on the rocks and mountains of Crete, but does not appear to be found wild any where else. Parkinson is said to have cultivated this beautiful plant in 1640; but it had long been lost to our collections, till Dr. Sibthorp brought seeds, which produced flowering plants at Dr. Pitcairn's, Ingleton, from whom we obtained a specimen in 1791, there being none previously in the Linnean herbarium. The wooden cuts of Pona and Imperati are good and original; but the best history of the plant is given, from Honorius Belli's letter to

Clusius, by the former. This all writers have copied, and Ventenat attributes the credit of some of it to J. Bauhin, who certainly has nothing original on the subject. Ventenat also errs, in his own observation, when he says the simple stigma disagrees with the character of *Phytocuma*. But this part, though drawn simply capitate in his plate, is truly three-cleft, as drawn by Bauer. The root is perennial, thick and milky, eaten, like that of *Campanula Rapunculus*, being suffused of an aphrodisiac quality. The first leaves are simply heart-shaped, like those of violets; the rest pinnate, sometimes interruptedly, a span long, smooth, deeply serrated; pale, and often purplish, beneath; their terminal leaflet heart-shaped, the rest obliquely ovate, stalked. Flowers very abundant, in a long, erect, terminal, dense, panicle, with cymose branches; their stalks glaucous and purplish; their corolla and stamens of a lilac hue.

PHYTOLACCA was first so called by Tournefort, from *φύλλον*, a plant, and *lacca*, a barbarous word, designating a kind of colouring substance; see LAKE or LAQUE; because the berries of several species of this genus afford a beautiful, though not lasting, purple or crimson dye.—Tourn. t. 154. Linn. Gen. 233. Schreb. 313. Willd. Sp. Pl. v. 2. 822. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 139. Sm. Prodr. Fl. Græc. Sibth. v. 1. 318. Juss. 84. Lamarck Illustr. t. 393. Gært. t. 77.—Class and order, *Decandria Decagynia*. Nat. Ord. *Holeraceæ*, Linn. *Atriplicæ*, Juss.

Gen. Ch. *Cal.* inferior, of five roundish, concave, spreading, coloured, permanent leaves, inflexed at the summit. *Cor.* none. *Stam.* Filaments ten, or eight, or twenty, awl-shaped, the length of the calyx; anthers roundish, lateral. *Pist.* Germen superior, orbicular, depressed, marked with alternate furrows and ribs; crowned with ten, or eight, or five, or seven, very short, spreading, reflexed styles; stigmas simple, permanent. *Peric.* Berry orbicular, depressed, furrowed, with ten, or eight, or five, or seven, cells, the summit hollowed, lodging the styles. *Seeds* solitary in each cell, kidney-shaped, smooth.

Obf. *Ph. dioica* has the flowers of distinct sexes, on different plants. Linnaeus having now fixed the place of this genus, amongst his *Holeraceæ*, not *Miscellaneæ*, it becomes necessary to reform his generic character, as to the flower having a calyx, not a corolla, on which subject he speaks with doubt in his Gen. Pl.

Ess. Ch. Calyx of five coloured leaves. Corolla none. Berry superior, of five or ten cells, and as many seeds.

The genus before us is remarkable for having all its specific differences depend on the number or situation of the organs of impregnation; so that, strictly speaking, every species belongs to a different class or order of the artificial system. No genus, notwithstanding this irregularity, can be more natural. Linnaeus knew but four species; Willdenow has six, five of them in the gardens of England. It is worthy of remark, that the two new species, discovered since Linnaeus wrote, differ in the number of their stamens and styles from each other, as well as from all those originally described, so as to preserve the unity of the principle according to which they are all discriminated.

1. *Ph. oelandra*. White-flowered Phytolacca, or Poke-weed. Linn. Sp. Pl. 631. Willd. n. 1. Ait. n. 1. (*Ph. mexicana*, *baccis* *fessilibus*; Dill. Elth. 218. t. 239. f. 308. Sjooriku, vulgò *Jamma* *Gobó*; Kämpf. Amoen. 828. t. 829.)—Stamens and styles eight.—Native of Mexico, as well as of Japan. The root is perennial, long and fleshy, according to Kämpfer eatable, and like a turnip. *Stem* herbaceous, thick, fleshy, alternately branched, leafy, smooth,

smooth, from three to six feet high. *Leaves* alternate, ovate; with a glandular point, smooth, wavy, veiny, resembling those of a *Rumex* or *Beta*, on thick stalks. *Flowers* white, numerous, in dense, cylindrical, terminal, solitary spikes. *Berries* sessile, black, the size of a large pea. The whole plant has a coarse rank habit, like a dunghill herb, and smells unpleasantly when bruised.

2. *Ph. stricta*. Erect Phytolacca. Willd. n. 2. Hoffm. Comm. Goett. v. 12. 27. t. 3. (*Ph. heptandra*; Retz. Obs. fasc. 6. 29.)—"Stamens eight. Styles seven. Leaves lanceolate, pointed."—Native of America. We have seen no specimen. Retzius describes it as follows. *Root* perennial. *Stem* two feet high, branched, erect, striated, smooth, hollow. *Leaves* scattered, stalked, lanceolate, entire, smooth, an inch and a half long. *Flowers* racemose, with several small awl-shaped bractees, at or near the base of their partial stalks. *Calyx* white within. *Stamens* seven. *Styles* six. *Berries* yellow, pellucid, of six distinct lobes, or grains. Hoffmann and Willdenow both give the number of *stamens* and *styles* as above.

3. *Ph. abyssinica*. African Phytolacca. Willd. n. 3. Ait. n. 2. Hoffm. Comm. Goett. v. 12. 28. t. 2. (*Ph. dodecandra*; L'Herit. Stirp. 143. t. 69.)—Stamens ten. Styles five. Said to have been brought from Abyssinia, by Mr. Bruce, in 1775. It is a shrub, kept in the stove, and flowering in May and June. *Stem* six feet high. *Branches* slender and spreading. *Leaves* stalked, spreading, ovate, wavy, tipped with an acute, reflexed, channelled point. *Clusters* long, drooping, downy, of many greenish downy flowers. *Berry* deeply lobed, red, with orange-coloured juice. L'Heritier found the *styles* and *seeds* most commonly but five; the *stamens* usually fifteen. Both are acknowledged to be variable. Our garden specimen, in the collection of the younger Linnæus, bears the name of *Ph. scandens*, which we find no where in print, nor does it seem to agree with the character of the shrub.

4. *Ph. decandra*. Common Phytolacca, or Virginian Poke-weed. Linn. Sp. Pl. 631. Willd. n. 4. Ait. n. 3. Curt. Mag. t. 931. Mill. Illustr. t. 36. —Stamens and styles ten.—Native of America, now naturalised in Spain, Portugal, Barbary, Zante and Greece. With us it is a tolerably hardy perennial, flowering from July to the end of autumn, forming a large herbaceous bush, decorated at once with clusters of greenish-white flowers and dark purple berries. The latter are said to have sometimes served in Portugal to improve the colour of such red port as is compounded in that country, not in England.

5. *Ph. icofandra*. Red Phytolacca. Linn. Sp. Pl. 631. Willd. n. 5. Ait. n. 4. (*Ph. spicis florum longissimis, radice annua*; Mill. Ic. v. 2. 138. t. 207.)—Stamens twenty. Styles ten.—Native of the East Indies. Annual with us, if planted abroad; but perennial in a stove, flowering in autumn. The *stem* is herbaceous, three or four feet high. *Leaves* rather narrower than in the last. *Clusters* erect, long, and taper-pointed, of numerous bluish-coloured flowers, the lowermost of which, Linnæus says, have certainly twenty *stamens*. By Miller's account the generality have much fewer. *Berries* dark purple, on rather short partial stalks.

6. *Ph. dioica*. Tree Phytolacca. Linn. Sp. Pl. 632. Willd. n. 6. Ait. n. 5. L'Herit. Stirp. 145. t. 70.—Flowers dioecious, with many *stamens*.—Native of South America. Miller cultivated this species in 1758, and L'Heritier says it is extremely common in European gardens. The Hortus Kewensis marks it as a stove shrub, without any mention of its flowering. The *stem* is thick, ten or twelve feet high, with round smooth leafy branches.

Leaves precisely ovate, pointed, smooth, entire, on long stalks. *Clusters* drooping, somewhat downy. *Flowers* greenish-white; the female ones smallest. *Berries* large, crowded, pale, much depressed and umbilicated.

The *leaves* of all the species that we have seen terminate in an awl-shaped, channelled, pale or coloured, somewhat glandular point, or appendage, which seems characteristic of the genus.

PHYTOLACCA, in *Gardening*, affords plants of the herbaceous hardy kinds, of which the species cultivated are; the white-flowered phytolacca (*P. octandra*); the branching phytolacca, or Virginian poke (*P. decandra*); the red phytolacca (*P. icofandra*); and the tree phytolacca (*P. dioica*).

The first sort is in some places found a palatable wholesome green: the tender stalks being frequently served up as young asparagus.

Also, in some places the young shoots of the second sort are boiled and eaten as spinach.

The fruit in the third sort is a globular berry.

Method of Culture.—The three first sorts may be increased by seeds, which should be sown in pots, in the spring, and plunged in a moderate hot-bed; when the plants have had a few inches growth, they should be removed into separate pots in the first and third sorts, but in the second into the borders or other parts, allowing them good room. The two former may be set out in warm borders or other places during the summer in pots, being carefully watered, shaded, and kept free from weeds.

The fourth sort may be raised by planting cuttings in the summer season, in pots filled with light earth, plunging them in the bark hot-bed and covering the pots with hand-glasses, proper shade being given. When well rooted, they should be removed into separate pots of a small size, replunging them in the hot-bed with proper shade till rooted, when they should be gradually inured to the open air, being removed into a moderate stove during the winter season.

The first sorts afford ornament and variety among potted plants of the stove kind; and the second sort, in the borders of the natural ground.

PHYTOLOGI, PHYTOLOGISTS, authors who have written any treatise on botany, or the history or uses of vegetables.

PHYTOLOGY, *φυτολογία*, compounded of *φυτον*, *plant*, and *λογος*, *discourse*, of *λεγω*, *I describe*, or *rehearse*, a discourse upon plants, or a description of their forms, kinds, properties, &c.

PHYTOTOMA, in *Ornithology*, a genus of birds of the order Passeres. The generic character is; bill conic, straight, ferrate; nostrils oval; tongue short and obtuse; feet four-toed. There is but a single species; *viz.*

RARA, which inhabits Chili, about the size of a quail; it has a harsh interrupted cry, resembling the syllables *ra ra*; it feeds on fresh vegetables, which it cuts down near the roots with its bill as with a saw, and is, on account of the mischief which it does to gardens, detested by the natives: it builds in high shady trees in retired places; the eggs are white, spotted with red. The bill of this bird is thick, and about half an inch long, toothed on each side like a saw; the irides are brown; the body above is of a dusky ash, beneath it is paler; the quill and tail-feathers are spotted with black; tail rounded; the hind toes shorter than the fore ones.

PHYZANIA, in *Ancient Geography*, the name of a country of Africa, according to Ptolemy.

PIA MATER, in *Anatomy*, one of the coverings of the brain. See **BRAIN** and *NERVOUS System*.

PIABA, in *Ichthyology*, the name of a small fresh-water fish, caught in all the rivers and brooks in the Brasils, and some other parts of America.

It is of the size of the common minow; is a well-tasted fish, and much esteemed by the natives.

PIABUCU, the name of an American fish eaten by the natives in many places. It is a ravenous fish, and so greedy of blood, that if a man goes into the water with a wound in any part of his body, this fish will make up to it to suck the blood: it is a small fish, seldom exceeding four inches in length. See *SALMO Argentinus*.

PIACENZA, in *Geography*. See **PLACENTIA**.

PIACHE, **PIAZZA**, a covered arched walk, or portico. See **PORTICO** and **PIAZZA**.

PIADA, in *Ancient Geography*, a town of Asia, in Serica, between Damna and Amirza. Ptolemy.

PIADELLA, in *Geography*, a town of Italy, in the department of the Lario; 20 miles N. of Como.

PIADENA, a town of Italy, in the department of the Mincio; 16 miles W. of Mantua.

PIAFFEUR, in the *Manege*, is a proud, stately horse, being full of mettle, or fire, restless and forward, with a great deal of motion, and an excessive eagerness to go forwards, makes this motion the more that you endeavour to keep him in, and bends his leg up to his belly. He snorts, traverses if he can, and by his fiery action shews his restlessness; whence some, though very improperly, say, he dances.

Such horses as these, or such as are bred to passage upon a straight line, are much admired in carousals and magnificent festivals. See **SNORT**, and **PASSADE**.

PIALAPOUR, in *Geography*, a town of Bengal; 20 miles N. of Dacca. N. lat. $23^{\circ} 35'$. E. long. $90^{\circ} 8'$.

PIALITZ, a river of Russia, in the government of Archangel, on the coast of the White sea, near Pialitza. N. lat. $66^{\circ} 10'$. E. long. $37^{\circ} 44'$.

PIALITZA, a town of Russia, in the government of Archangel, on the coast of the White sea; 100 miles N. of Archangel.

PIAL-ÜL-GEEL, a town of Prussia, in the circle of Natangen; 10 miles E. of Lick.

PIALZY, a town of Hindoostan, in the country of Dindigul; 23 miles W.N.W. of Dindigul. N. lat. $10^{\circ} 28'$. E. long. $17^{\circ} 37'$.

PIANA, a town of the island of Corsica; nine miles N.W. of Vico.—Also, a river of Russia, which runs into the Sura, near Yadrin, in the government of Kazan.—Also, a small island near the N. coast of Sardinia. N. lat. 41° . E. long. $8^{\circ} 27'$.—Also, a small island near the W. coast of Sardinia. N. lat. $39^{\circ} 17'$. E. long. $8^{\circ} 25'$.—Also, a small island in the Mediterranean, near the coast of Naples. N. lat. $40^{\circ} 13'$. E. long. $12^{\circ} 55'$.

PIANEG, a town of Russia, in the government of Viatka; 16 miles E.N.E. of Yarensk.

PIANELLO, a town of the island of Corsica; 18 miles E. of Corte.

PIANEZZA, a town of France, on the Dora; four miles W. of Turin.

PIANISSIMO, in the *Italian Music*. See **PIANO**.

PIANKANSHAWS, or **PYANKESHAWS**, *Vermilions* and *Muscontins*, in *Geography*, are tribes of Indians in the Indiana territory, who reside on the Wabash and its branches, and Illinois river. These, with the Kickapoos, Musquitos, and Ouatanons, could together furnish about 1250 warriors, in the year 1780.

PIANKATUNK, a small river of Virginia, which runs E. into Chesapeake bay, opposite to Gwin's island; navigable eight miles for small craft.

PIANO, a town of Italy, in the department of the Panaro; 16 miles S.W. of Modena.

PIANO della Corte, a town of Naples, in Principato Citra; 12 miles N.N.W. of Cangiano.

PIANO Picola, a town of Naples, in Capitanata; two miles W. of Vieste.

PIANO, an Italian musical term implying soft, with a subdued voice, was at first only used in repeating short passages in the way of echo. It was no otherwise used by Corelli. At present its use is extended to whole periods in the way of chiaro-scuro, and contrast to *forte*, loud, in every degree of comparison. It is abridged to *pia*, and the initial letter P., as is its superlative degree, *pianissimo*, to *pianis*, and *pp.* Sometimes *pp.* stands for *pian piano*, when it has somewhat more force.

PIANO Forte, a keyed instrument, of which the tone is produced by hammers instead of quills, like the virginal, spinet, and harpsichord. There is a minute account of the invention, and a description of the piano forte, in the "Giornale d'Italia," tom. v. p. 144, printed at Venice, 1711. This instrument was invented at Florence, by Bartolommeo Cristofali, harpsichord maker, a native of Padua, in the service of the grand duke of Tuscany. For the history of the piano forte, see **HARPSICHORD**.

PIANOSA, in *Geography*, a small island in the Mediterranean, near the coast of Etruria, anciently called "Plunatia," and used as a place of exile. Its flat surface is a league in extent, elevated only a few feet above the level of the sea; an uncultivated rock, abandoned to wild goats; dangerous to navigators in the night; seven miles S.S.W. from the island of Elbe. N. lat. $42^{\circ} 42'$. E. long. $10^{\circ} 15'$.

PIAPET, or **MAGPIE**, in *Ornithology*. See **CORVUS Pica**.

PIAPIS HARBOUR, in *Geography*, a port on the N. coast of the island of Waygoo, on the Equator. E. long. $130^{\circ} 45'$.

PIAQUEMINES, a river of Louisiana, which runs into the Missouri, N. lat. $38^{\circ} 25'$. W. long. $91^{\circ} 37'$.

PIARANTHUS, in *Botany*, from *πικρός*, fat or thick, and *ανθος*, a flower, a genus separated by Mr. R. Brown from *Stapelia*, because it wants the external crown. Brown Tr. of the Wernerian Society, v. 1. 23. Clafs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocinea*, Juss. *Asclepiadeæ*, Brown.

Ess. Ch. Corolla bell-shaped, five-cleft, fleshy, including the column of fructification. Crown of the stamens single, of five leaves, toothed at their back. Anthers simple at the summit. Masses of pollen erect, attached by the base, cartilaginous and pellucid at one edge. Stigma pointless. Foli- cles

There are but two certain species.

1. *P. punctatus*. (*Stapelia punctata*; Masson Stapel. 18. t. 24. Willd. Sp. Pl. v. 1. 1289. Ait. Hort. Kew. v. 2. 92.)—Branches decumbent, jointed. Flower-stalks axillary, longer than the corolla. Found by Mr. Masson in the Namaqua lands, at the Cape of Good Hope. He sent it to Kew in 1795, and it flowers there, in the dry stove, during most part of the autumn. The joints of the branches are obovate, squarish, of a dark glaucous green, beset with numerous prominences, each of which is tipped with a brown tooth. *Flower-stalks* axillary from the prominences, several together, an inch and a half long, smooth, purplish, single-flowered. *Flowers* about an inch wide; internally pink,

pink, dotted with minute crimson tubercles: externally whitish; the segments spreading, acute.

2. *P. pullus*. (*Stapelia pulla*; Masson Stapel. 21. t. 31. Willd. Sp. Pl. v. 1. 1288. Ait. Hort. Kew. v. 2. 92.) —Branches erect, with about six angles. Flower-stalks lateral, shorter than the corolla. Discovered by Mr. Masson in the hot sandy region of Karrò in southern Africa. He introduced it at Kew so early as 1774, and it flowers in August and September in the dry stove. The stems or branches form a thick tuft, about a span high, of a light green, slightly glaucous; their angles beset with strong brown teeth. Flowers two or three together, on short simple stalks, from the sides of the branch, remote from the teeth. Corolla about an inch long, slightly spreading, acute; dark brown within; whitish, with five purple ribs, without; the edges revolute.

These plants so precisely accord with various *Stapelia* in every point of habit, that we should presume the singleness of the crown can afford no legitimate generic distinction, any more than the difference between five and ten stamens in *Cerastium*, the want or presence of a nectary in *Tilia*, and other similar cases.

PIASANSKOI, NIZNEI, in *Geography*, a town of Russia, in the government of Tobolsk, near the Frozen sea. N. lat. 69° 16'. E. long. 87° 14'.

PIASANSKOI, *Verebnei*, a town of Russia, in the government of Tobolsk, near the Frozen ocean. N. lat. 68° 30'. E. long. 87° 14'.

PIASKY, a town of Poland, in the palatinate of Lublin; 12 miles E.S.E. of Lublin.

PIASTER, or PIASTRE, a Spanish money, more ordinarily called a *piece of eight*.

PIASTLA, in *Geography*, a town of Mexico, in the province of Chiametlan, on the river Piaftla, which runs into the Pacific ocean, N. lat. 23° 25'. The town is situated at the distance of 50 miles N.W. of Chiametlan.—Also, a town of Mexico, in the province of Gualteca; 15 miles S. of Panuco.—Also, a town of Mexico, in the province of Tlafcala; 55 miles S. of Puebla de los Angeles.

PIASTRE, in *Commerce*. See PIASTER, or PIECE of eight.

PIASTRE is also a money of account and silver coin in Turkey, and the Levant. The piastre of Aleppo, and of its port, Alexandretta or Scanderoon, is accounted at 80 aspers, or 24 syaios. The piastres of Alexandria are valued at 40 medini, each medino being subdivided into 8 borbi, or 6 forli, or 3 aspers. The piastre at Algiers is the same with the *pataca gourda*, which see. At Grand Cairo accounts are kept, by European merchants, in piastres of 40 medini; but the Levanters reckon only in medini.

Constantinople and the whole of Turkey keep accounts in piastres, commonly called grouch by the Turks, and by the English, dollars. Each piastre is divided into 40 paras, and each para into three aspers. These are real coins; but the piastre is also sometimes divided into 80, and sometimes into 100 imaginary parts, called aspers, or minas. A jux or juck is a sum of 100,000 real aspers: a chise or purse is 500 ditto. The gold coin, called sequin fonducli, was coined in 1764; 100 of these weigh 5415 English grains, and they are about 23 carats fine; it passed at first for 3½ piastres, or 440 aspers, but its price was gradually raised to four piastres; and in 1769 most of them were called, in for a new coinage. The dollar or piastre is a silver coin of 40 paras. By the regulations of 1780, the purse of 500 piastres was to weigh 2812½ Turkish drams, so that a single piastre weighed 5½ drams, or 277 English grains, and the other pieces in proportion. The standard

of fineness was reduced at the same time to 50 carats (or hundredth parts) of fine silver, and 50 of alloy; which gave the value of the piastre at 19¼d. sterling, and the other silver coins in proportion. But since that period the Turkish have suffered a deterioration. Dr. Kelly, the author of the Universal Cambist, has caused a piastre of the latest coinage to be weighed and assayed, by the king's assay-master of the mint, and the report is as follows: weight, 8 dwt. 6 gr. Fineness, 5 oz. 6 dwt. worse than the English standard. This gives its fineness 47 carats 2 grains Turkish, and its value in sterling 13½d. Venetian sequins pass at present for 9½ piastres; Dutch, Imperial, and Hungarian ducats, for 9 piastres; Spanish dollars, and German six-dollars or Imperial tallaris (called by the Turks cara grouch) for 4½ piastres.

Damascus keeps accounts in piastres of 80 aspers like Aleppo, and has the same coins as Constantinople. Smyrna keeps accounts in piastres or dollars; which the English and Swedes reckon at 80 aspers; the Dutch, French, and Venetians at 100; and the Turks, Greeks, Persians, and Armenians, at 120 aspers. This piastre (called by the Turks grouch) is also divided into 12 temins, and 40 paras or medini. Tripoli keeps accounts in piastres, of 13 grimellini, or 52 aspers. The grimellini is valued at 6 fous Tournois, which makes the piastre of Tripoli worth 3s. 3d. sterling. At Tunis accounts are kept in piastres, of 52 aspers; each asper being divided into 12 borbes.

The assay, &c. of the Turkish piastres is as follows:

	Assay.	Weight.	Contents in pure Silver.	Value in Sterling.
	oz. dwt. grs.	oz. dwt. grs.	grains.	s. d.
Piastre of Mustafa III. (1757)	W. 4 11	0 12 7	161	1 10½
Piastre of Abdul Hamed (1773)	W. 5 2	0 12 7	147.5	1 8½
Another of the same period	W. 4 9	0 12 0	159.6	1 10¼
Double piastre of Selim (1789)	W. 5 12	0 16 22¼	186.4	2 2
Piastre of Selim (1801)	W. 5 6	0 8 0	96.7	1 1¼
Half piastre	W. 6 13	0 4 1	35.9	0 5
Piastre of Crim Tartary (1778)	W. 6 13	0 10 5	91.9	1 0½
Piastre of Tunis (1787)	W. 6 5½	0 10 0	96.5	1 1½

N.B. W. denotes worse than English standard.

The piastre and other silver coins bear the same inscriptions as the gold coins, and the same differences exist in them. The inscriptions on the single, double, and half piastres of Selim of 1789 are similar to those on the sequin fonducli of this prince, which has on one side, *Sultan Selim, son of Mustafa Khan*, and on the reverse, *Struck at Slambul, in the year 1203*, being the date of the Hegira, which began in 622 of the Christian era. The piastre of Tunis bears on one side the words, *Sultan of the two lands, and sovereign of the two seas, Sultan Selim Khan, blest with victory*; and on the reverse, *Struck at Tunis, in the year, &c.* See Kelly's Universal Cambist.

PIASTRE is also the French for a dollar; which see.

PIASTRINE. See PISTEREEN.

PIAT SOPOK, in *Geography*, a cluster of five islands; among

among the Fox islands, in the North Pacific ocean. N. lat. $53^{\circ} 24'$. E. long. $189^{\circ} 46'$.

PIATEK, a town of Samogitia; 15 miles N.N.E. of Miedniki.

PIATEK, or *Piontek*, or *Prontko*, a town of the duchy of Warfaw, celebrated for its beer; eight miles N.N.E. of Lenczicz.

PIATIA, a town of Naples, in Calabria Ultra; eight miles S.W. of Gierace.

PIATIGER, a town of Russia, in the government of Viatka; 16 miles E. of Kai.

PIATNITZKA, a town of Russia, in the government of Tobolsk; 28 miles N.N.W. of Eniseisk.

PIATTA, a town of Italy, in the county of Bormio; two miles S. of Bormio.

PIATTI. See PATTI.

PIATZINA, a town of Russia, in the government of Olonetz; 32 miles N.W. of Kargopol.

PIAUBAU, in *Ornithology*. See *MUSCICAPA Rubricollis*.

PIAVE, in *Geography*, a river which rises in the Tyrolese, crosses the Feltrin and Trevisan, and runs into the Adriatic; 16 miles N.E. of Venice.

PIAVO, a lake of Russia, in the government of Archangel. N. lat. $66^{\circ} 30'$. E. long. $30^{\circ} 14'$.

PIAW, a river of Mexico, which runs into the bay of Honduras, N. lat. $15^{\circ} 52'$. W. long. $85^{\circ} 50'$.

PIAZIDA, a river of Russia, which rises in lake Piazinskoi, in the government of Tobolsk, N. lat. $69^{\circ} 40'$. E. long. $89^{\circ} 14'$, and runs into the Kargskoi sea, at Verchnei Piazinskoi. N. lat. $73^{\circ} 30'$. E. long. $87^{\circ} 14'$.

PIAZZA, a town of Naples, in Principato Citra; 14 miles E.N.E. of Salerno.—Also, a town of Sicily, in the valley of Noto, situated nearly in the centre of the island, and containing 18,000 inhabitants; 25 miles N. of Alicata. N. lat. $27^{\circ} 23'$. E. long. $14^{\circ} 22'$.

PIAZZA, in *Building*, properly called *piache*, an Italian name for a portico, or covered walk, supported by arches. The word literally signifies a broad open place, or square; whence it also became applied to the walks, or porticos around them. See PORTICO.

PIAZZOLA, in *Geography*, a town of Corsica; 3 miles E.S.E. of La Porta.

PIBERSTAIN, a town of Austria; 10 miles W. of Freystatt.

PIBGORN, Welsh. See HORNPIPE.

PIBIGGA, in *Geography*, a town of Hindoostan, in Bahar; 35 miles S.W. of Patna.

PIBRAC, a town of France, in the department of the Upper Garonne; 9 miles W. of Touloufe.

PIC, or PIKE, in *Commerce*, a long measure in Turkey, which at Aleppo is equal to 299.8 French lines, or $26\frac{1}{2}$ English inches. At Constantinople it is of two sorts: the longest, called Halebi, or Archim, with which silks and woollens are measured, is 314 French lines, or $27\frac{1}{2}$ English inches in length; the other, called Endasse, with which cotton goods and carpets are measured, is 3 per 100 shorter. But in the general course of European trade the pike is reckoned at $\frac{1}{4}$ th of an English yard. But in different places it is of different lengths. In the isle of Cyprus the pic or ell measures $26\frac{1}{4}$ English inches. At Damascus it is $22\frac{1}{2}$ English inches. The Morocco pic, or pic Morisco is $26\frac{1}{4}$ English inches; so that 108 pics = 79 English yards. The long pic of Algiers is $24\frac{1}{2}$ English inches, and the short pic = 18.4 inches. The pic of Candia is 25.1 English inches; that of Corfu, 22.6; that of Jerusalem, 27; that of Negropont, 23.4; that of Oran, 27;

that of Rhodes, 29.7; the long pic of Scio, 27, and the short, 26; that of Sidon, 23.8; that of Smyrna, 27; that of Tripoli, 27; the woollen pic of Tunis, 26.5; the silk ditto, 24.8; and the linen ditto, 18.6 English inches.

PIC de l'Etoile, *Le*, in *Geography*, a small island in the South Pacific ocean, so named from its resemblance in form to a sugar-loaf, by M. Bougainville in 1768. It is one of the group called by Quiros "Terra Austral del Spiritu Santo," by Bougainville "the Archipelago of the Great Cyclades," and by Cook "New Hebrides." S. lat. $14^{\circ} 29'$. E. long. $168^{\circ} 9'$.

PIC Lamanon, a mountain on the W. coast of the island of Saghaliens, so called by Peroufe. N. lat. $48^{\circ} 40'$.

PIC Martiniere, a mountain on the W. coast of Saghaliens, so called by Peroufe, after the name of a French botanist, the companion of his voyage, on account of the great number of curious plants found there.

PIC de Luco, a town of the duchy of Spoleto; 16 miles S.S.E. of Spoleto.

PIC-beuf, in *Ornithology*. See BUPHAGA *Africana*.

PIC de Cayenne, *Petit*. See YUNX *Minutissima*.

PIC Noir, &c. &c. See PICUS.

PICA, or PYE, in *Ecclesiastical Antiquity*, was a term formerly used in the same sense with *ordinal*, for a table or directory, pointing out the order in which the devotional services appointed for different occasions were to be performed. Accordingly some derive it from ΠΙ, a contraction of πικρῶς, a table; and others from *litera picata*, a great black letter at the beginning of some new order in the prayer. In much the same sense the term was used by officers of civil courts, who called their calendars or alphabetical catalogues directing to the names and things contained in the rolls and records of their courts, the *Pyer*.

PICA, in *Geography*, a river of South America, which runs into the Pacific ocean, forming a harbour at its mouth. S. lat. $20^{\circ} 12'$.

PICA de Regalados, a town of Portugal, in the province of Entre Duero e Minho; 5 miles N.N.E. of Braga.

PICA, in *Medicine*, called also *malacia*, and by the Greeks *πιττα*, *citta*, signifies a depraved state of the appetite, which induces the patient to crave and swallow unusual and indigestible things, such as chalk, ashes, coals, pitch, salt, cinders, &c. Why the appellation of *pica* was given to this morbid appetite we know not: some writers assert that the bird called *pica* (the pic) is subject to the disease.

This morbid longing for uneatable substances occurs principally in women, and that under two conditions of the uterine system; namely, in a state of chlorosis, in the unimpregnated female, and in the early months of pregnancy. The proximate cause of the deranged appetite is, doubtless, a morbid state of the stomach and its secreted fluids, which we know to be commonly produced by the sympathy with the uterus in the early period of pregnancy in general, and to accompany the chlorotic condition. It has been supposed that the prevalence of an acid in the stomach occasioned this demand for earthy and absorbent substances: but many of the substances, taken in different instances, are not possessed of any antacid qualities. The disorder is very frequently beyond the power of medicine to relieve in a direct way. In the case of pregnancy, it commonly ceases altogether about the fourth month, and has been relieved by blood-letting in strong and plethoric women: but in chlorotic girls it is only removed by the course of medicine, which removes the morbid state of the habit in general, and restores the natural discharge where that was suspended. See CHLOROSIS.

PICA *Nasi*, a name given by Cohaufen to the immoderate taking

taking of snuff. It seems a whimsical term, but he chooses to treat this habit as a disease, and has written an express treatise concerning it. The word *pica*, in general, denotes an absurd and unnatural appetite; and the desire of taking the powder of tobacco in this manner is called a distempered appetite of the part into which it is taken, that is, the nose.

The consequences of the taking snuff immoderately, are, that the sense of smelling is either entirely destroyed, or at least greatly impaired: for the nervous tubercles of the nostrils being continually vellicated by this powder, are by degrees clogged up, or wholly destroyed, and the sensible membrane, which lines the nostrils, is rendered callous, and wholly unfit for the discharge of its office in smelling. The voice is next affected by this powder; for it causes a sort of stricture at the bottom of the nose, which affects the palate, and consequently the speech; this gives the person who takes it a continual desire of taking more and more, to rid himself of that stoppage.

PICA, in *Ornithology*, the *Magpie*, a species of *Corvus*; which see.—Also, a species of *Alca*, the black-billed auk of Pennant and Latham. See ALCA.

PICA is also a name by which some have called the *lanius*, or *butcher-bird*. See LANIUS.

PICA *Brasiliensis*. See MEROPS *Brasiliensis*.

PICA *Glandaria*, the *Jay*. See CORVUS *Glandarius*.

PICA *Glandaria carulea cristata*, the *Blue Jay*. See CORVUS *Cristatus*.

PICA *Jamaicensis*. See GRACULA *Quiscalis*.

PICA *Maderaspatana*, &c. of Ray. See ORIOLUS *Melanocephalus*.

PICA *Marina*, *Puffin*. See ALCA *Arctica*.

PICA *Marina*. See HEMATOPUS.

PICA *Papueusis*. See TODUS *Paradisacus*.

PICA *Papueusis* of Brisson. See MUSCICAPA *Paradisif*.

PICA *Persica*. See ORIOLUS *Persicus*.

PICA, in *Printing*. See PRINTING.

PICACIA, a name given by the ancients to that distempered appetite of women with child, and maidens at a certain time of life, which makes them long for things not fit for food. It is more usually called *pica*.

PICACUROBA, in *Ornithology*, the name of a Brazilian species of pigeon, of a greyish colour, variegated with a reddish-brown, and with very red legs and feet. See COLUMBA *Carolinensis*.

PICÆ, the second order of the class AVES in the Linnæan system. The distinguishing characteristics of this order of birds are; a bill somewhat compressed, more or less crooked, and always convex; toes divided, and adapted either for climbing or for stepping. Some of them feed on insects, worms, and the flesh and offal of other animals, and some on the seeds and juices of plants. During the breeding season they are monogamous, and make their nests in trees; and during the time that the female is sitting, she is fed by the male. There are twenty-six genera, divided into sections.

A. Feet formed for perching: this section contains

Buphaga,	Oriolus,
Certhia,	Paradisæa,
Coracias,	Sitta,
Corvus,	Trochilus,
Glaucoptis,	Upupa.
Gracula,	

B. Feet formed for climbing, containing

Bucco,	Pittacus,
Crotophaga,	Rhamphastos,
Cuculus,	Scythrops,
Galbula,	Trogon,
Picus,	Yunx.

C. Feet formed for walking, containing

Alcedo,	Momotus,
Buceros,	Todus.
Merops,	

PICANING, in *Geography*, a town of Africa, on the Ivory coast. N. lat. 5° 25'. W. long. 4° 35'.

PICARA, a large province of South America, in New Granada; bounded on the east by the Andes.

PICARD, in our *Old Writers*, a kind of large boat, about fifteen tons or upwards, used on the river Severn. Stat. 35 Hen. VIII. cap. 9. 13 Eliz. cap. 11.

PICARD, JOHN, in *Biography*, an able French astronomer and mathematician in the 17th century, was born at Flèche, in Anjou, but in what year is not known. He was educated for the church, but had a strong thirst for mathematical knowledge, and for those other branches of science that depend upon it, particularly for astronomy. Coming to Paris, his talents soon rendered him known and respected; and as the Academy of Sciences was at that time forming, he was selected to become one of its members, and was associated with them in the year 1666, with the appointment of astronomer to the academy. In the same year he published a new micrometer, for measuring the smallest apparent diameters of the stars, and their least sensible distances. In 1671 he was sent by order of the king to the observatory of Uraniberg, on the island of Huen, in the Sound, not far from Copenhagen, in order that by astronomical observations on the spot, he might determine, with the greatest exactness possible, the true elevation of the pole, and the longitude of that place, for the purpose of adapting to the meridian of Paris the astronomical tables on the observations of Tycho Brahe. He was commissioned likewise to collect, as far as possible, the original manuscripts of Tycho Brahe's observations which had been printed in Germany. He was successful in his researches, and the MSS. were found to differ in many respects from the printed copies, and they contained a book more than had been printed. He traversed several parts of the kingdom of France for the purpose of measuring the degrees of the French meridian, and he first gave a chart of the country, which the celebrated Cassini carried to a great degree of perfection. He was one of the first who applied the telescope to astronomical quadrants; and he was the projector of the work entitled "Connoissance des Temps," which he calculated from 1679 to 1683 inclusively. He died in the last named year: his chief works are as follow: "A Treatise on Levelling;" "Practical Dialling by Calculation;" "Fragments of Dioptrics;" "De Mensuris;" "De Mensura Liquidorum et Aridorum;" "An Abridgment of the Measure of the Earth;" "A Journey to Uraniberg, or Astronomical Observations made in Denmark." These and other of his pieces are to be found in the 7th and 8th vols. of the *Memoirs of the Academy of Sciences*. Moreri.

PICARDS, in *Ecclesiastical History*, a religious sect, which arose in Bohemia in the 15th century, so called from its author, who, because he originally came from Picardy, was called *Picard*. He drew after him, as it has been said,

a great number of men and women, pretending he would restore them to the primitive state of innocence in which Adam was created: and accordingly himself assumed the title of the New Adam.

Under this pretence (say their enemies) he taught his followers to abandon themselves to all impurity; making them believe, that in this consisted the liberty of the sons of God; and that all those not of their sect were in bondage.

He first began in Germany and the Low Countries, persuading many people to go naked, and giving them the name of Adamites. After this, seizing an island in the river Laufnez, a few leagues from Thabor, the head quarters of Zisca, he fixed himself and his followers therein; appointing his women to be common, but allowed none to enjoy them without his permission: so that when any man desired a woman, he carried her to Picard, who gave him leave in these words, "Go, increase, multiply, and fill the earth."

At length Zisca, the great general of the Hussites, (so famous for his victories over the emperor Sigismund), struck with their abomination, marched against them; and, making himself master of their island, put them all to death except two; whom he spared to inform himself of their doctrine.

Such is the erroneous and injurious account, as many have thought, which different writers, ultimately relying on the insufficient authorities of Æneas Sylvius and Varillas, have given of the Picards, who seem to have been a party of the Vaudois, or Waldenses, that fled from persecution in their own country, and sought refuge, about the beginning of the 15th century, in Bohemia. It is very doubtful whether a sect of this denomination, chargeable with the licentious principles and conduct above recited, ever existed; and we cannot forbear expressing our astonishment that Mr. Bayle, in his art. *Picards*, should adopt the reproachful representations of the writers just mentioned.

It is most probable, as competent and candid judges have maintained, that the whole or a great part of these charges is either an exaggeration or a calumny invented and propagated, in order to disgrace the Picards, because they deserted the communion and protested against the errors of the church of Rome. Lactantius relates, that Picard settled in Bohemia in the year 1418, accompanied by forty other persons, besides women and children. The Jesuit Balbinus, in his *Epitome Rerum Bohemicarum*, lib. ii. concurs in this account, and charges on the Picards none of the extravagancies or crimes ascribed to them by Sylvius. Schlecta, secretary of Ladislaus, king of Bohemia, in his letters to Erasmus, gives a particular account of the Picards; representing them as persons, who considered the pope, cardinals, and bishops of Rome, as the true Antichrists; who censured those that adored the consecrated elements in the eucharist as idolaters, and denied the corporal presence of Christ in this ordinance; who condemned the worship of saints, prayers for the dead, auricular confession, the penance imposed by priests, the fasts and vigils observed in the Romish church; and confined themselves to the observance of the sabbath, and of the two great feasts of Christmas and Pentecost. From this abstract of their sentiments, it sufficiently appears, that they were no other than the Vaudois; and M. de Beaufobre has plainly shewn that they were both of the same sect under different denominations. Besides, it is a certain fact, that the Vaudois were settled in Bohemia in the year 1178, where some of them adopted the rites of the Greek church, and others those of the Latin church. The

former were generally adhered to till about the middle of the fourteenth century, when the establishment of the Latin rites occasioned great disturbance. When the national troubles commenced in Bohemia, on occasion of the opposition to the papal power (see *MORAVIANS*), the Picards appeared more publicly in the avowal and defence of their religious opinions; and they formed a considerable body in an island by the river Launitz or Laufnez, in the district of Bechia, and recurring to arms, were defeated by Zisca. *Encyclop. art. Picards.*

Mosheim considers the Picards as deriving their name from that of the *Begbards* (see that article), by a change in the pronunciation of that word, and concurs in the unfavourable account of them given by the writers to whom we have already referred. He represents them as appearing in the religious assemblies, and joining in the celebration of divine worship, without any veil or covering whatever; agreeably to the maxim which they are said to have adopted, *viz.* that those were not free (*i. e.* sufficiently extricated from the shackles of the body) who made use of garments, particularly such garments as covered the thighs and the parts adjacent. But though he mentions this practice, and denominates them an absurd sect, which by such tenets incurred deserved reproach, he acknowledges that in their religious assemblies nothing passed that was contrary to the rules of virtue, however they were suspected of the most scandalous incontinence, and of the most lascivious practices. He states that Zisca, the austere general of the Hussites, gave credit to the rumours that were industriously circulated against them; and falling upon them in the year 1421, put some to the sword, and condemned the rest to the flames, which dreadful punishment they sustained with the most cheerful fortitude, and also with a contempt of death that was peculiar to their sect, and which they possessed in a degree that seems to surpass credibility. These extravagant enthusiasts, he says, were distinguished by other appellations, such as those of *Adamites* and *Begbards* (see these articles), and the denomination was extended so as to comprehend the Hussites, and all the Bohemians who opposed the tyranny of the church of Rome. They were called by their enemies, and indeed by the multitude in general, "Picardiers." He says that Beaufobre, in his attempts to justify the Picards, or Bohemian Adamites, against the accusations of their enemies, which he considers as altogether groundless, is manifestly endeavouring to wash the Ethiopian white: and he adds, that it may be demonstrated, by the most unexceptionable and authentic records, that his account is true; suggesting at the same time a charge of prejudice and partiality against the respectable and learned author from whom he differs. *Ecccl. Hist. vol. ii. p. 464, note.*

PICARDY, in *Geography*, a considerable province of France before the revolution, which now forms the departments of the Somme, part of the department of the straits of Calais, and the department of the Aisne; which see respectively.

PICARY, in *Zoology*, a name given by Bancroft, in his "Guiana," to the *Sus Taji-fu*; which see.

PICATUM VINUM. See **VINUM**.

PICAUVILLE, in *Geography*, a town of France, in the department of the Channel; 9 miles N.W. of Charantan.

PICAWEEES, Indians of America, on the banks of the Great Miami.

PICCINI, NICOLA, in *Biography*, born in 1728 at Bari, capital of the little province of that name, in the kingdom

PICCINI.

kingdom of Naples, may be ranked among the most fertile, spirited, and original composers that the Neapolitan school has produced. An invincible passion for music frustrated the intention of his father, who designed him for the church, and made him study for that intent; but for fear of his neglecting serious business for amusement, he would not let him learn music. The young man, whose genius suffered him not to rest, never saw an instrument, especially a harpsichord, without emotion; he practised in secret all the opera airs which he had heard, and which he retained with surprising accuracy. His father having carried him one day to the bishop of Bari, he amused himself in the room where he was left alone, with a harpsichord which he found there, thinking he could be heard by no one; but the prelate in the next apartment having heard him, condescended to go to the harpsichord, and obliged him to repeat many of the airs which he had been playing; this he did with so much accuracy and precision, with the ritornelle and accompaniments, which he likewise remembered, that the bishop persuaded his father to send him to the Conservatorio of St. Onofrio, at Naples, of which the celebrated Leo was then the principal master.

The young Piccini was admitted in that seminary in 1742, and was placed at first under the tuition of a subaltern master, whose lessons, given in a dry and contracted manner, soon disgusted him: and in a few months his discontent at such unprofitable instructions drew on him the resentment of his tutor, expressed in no very gentle way. Shocked with this treatment, he resolved to study by himself, and began composing without rules, or any other guides than his own genius and fancy, psalms, oratorios, and opera airs; which soon excited the envy or admiration of all his fellow students. He even had the courage to compose an entire mass. One of the masters who had seen it, and even permitted him to have it rehearsed, thought it right to mention it to Leo; who, a few days after, sent for Piccini to come and speak to him. The young man, penetrated with the highest respect for so great a master, which is in some sort an intuitive indication of genius, was extremely frightened at this message, and obeyed the order with fear and trembling. "You have composed a mass," said Leo, with a cold, and almost severe countenance: "Yes, sir." "Shew me your score,"—"sir, sir,"—"shew it me, I say." Piccini thought himself ruined; but he must obey. He fetched his score, at which Leo looked, turned over the leaves, examined each movement, smiled, rung the bell, as the signal for a rehearsal. The young composer, more dead than alive, begged in vain to be spared what he thought such an *affront*. The singers and instrumental performers obeyed the summons; the parts were distributed, and the performers waited only for Leo to beat the time. When turning gravely to Piccini, he presented him the *baton*, which was then used every where in the performance of full pieces. Piccini, put to new confusion, offered fresh prayers to be excused obeying this command, wishing he had never dared to meddle with composition. At length he mustered his courage, and marked with a trembling hand the first bars. But soon animated and inflamed by the harmony, he neither saw Leo, nor the standers by, who were numerous; he was absorbed in his music, and directed its performance with a fire, energy, and accuracy which astonished the whole audience, and acquired him great applause. Leo kept a profound silence during the performance: when it was over,—"I forgive you, for once," said he, "but if you are again guilty of such presumption, you shall be punished in such a manner as you will remember as long as you live. What! you have received from nature so estimable a disposition for

study, and you lose all the advantages of so precious a gift! Instead of studying the principles of the art, you give way to all the wild vagaries of your imagination, and fancy you have produced a master-piece." The boy, piqued by these reproaches, related what had passed between him and the assistant master under whom he was placed. Leo became calm, and even embraced and caressed him; ordering him to come to his apartments every morning, to receive instructions from himself.

This truly great master died suddenly some months after. Happily for his promising pupil, his successor was the celebrated Durante, one of the most learned composers Italy ever produced. He soon distinguished Piccini from the rest of his class; conceived a particular affection for him; and had pleasure in communicating to him all the secrets of his art. "Others are my pupils," he sometimes used to say, "but this is my son."

At length, after twelve years' study, Piccini, in 1754, quitted the Conservatorio, knowing all that is permitted to an individual to know in practical music, and possessed of such a creative and ardent imagination, as perhaps, till then, was unexampled.

He began his career at the Florentine theatre in Naples, which is that of San Carlo, what Foote's theatre used to be compared with Drury Lane, or the Opera House. His first production there was "Le Donne Dispettose," and the next year, "Le Gelosie," and "Il Curioso del suo Proprio Danno," of all which the success increased in a duplicate ratio. At length, in 1756, he set the serious opera of "Zenobia" for the great theatre of San Carlo, which was crowned with still greater success than his comic operas. In 1758, he composed "Alessandro nell' Indie," for Rome; and after this, every theatre in Italy was eager to engage him. In 1760, his celebrated comic opera of the "Buona Figliuolo" had a success that no musical drama could boast before. It was no sooner heard at Rome than copies were multiplied, and there was no musical theatre in Europe where this burletta was not frequently performed, in some language or other, during many years. In 1761, he composed six operas, three serious and three comic, for different theatres of Italy; and was at once applauded in Turin, Reggio, Bologna, Venice, Rome, and Naples. Sacchini assured us, in 1776, that Piccini had composed at least three hundred operas, thirteen of which were produced in seven months. On his arrival at Paris, he received many mortifications before his reputation was firmly established, from the partizans of the old French music, as well as the friends of Gluck. The success of his operas of "Roland," "Atys," "Iphigénie en Tauride," "Adele de Ponthieu," "Didon," "Diane et Endymion," and "Penelope," seems to have solved a problem which was long thought insolvable: "Whether the French language was capable of receiving Italian melody?"

If we add to so many dramatic works the oratorios, masses, cantatas, and occasional songs and scenes in pasticcio operas, it would prove, that in twenty-five years he had produced more music, and good music, than any other ten masters had done in their whole lives.

What still more astonishes in such innumerable works, is the prodigious variety which reigns in them all; and the science which never degenerates into pedantry or affectation; an harmony pure, clear, and profound; a melody perfectly suited to the subject and situation of the performers; and a force, an originality, and resources of all kinds, unknown till his time, and of which perhaps the secret will long remain undiscovered. And what appears as extraordinary as the rest is, that the genius of this

master, far from being exhausted by so many labours, by frequent and severe sickness, by domestic disquietude and chagrin, inseparable from a numerous family, seemed, before the revolution, to continue in full force. Deprived of all his appointments, and well-earned theatrical pensions, he returned to Naples, where, after he had established himself in France, all his appointments had been disposed of. Unluckily, on the arrival of a French army at Naples, he either did adhere to the invaders, or was supposed by the court to be in correspondence with them, which occasioned his disgrace, and precipitated his flight back to Paris, where he was received with open arms, and placed at the head of a new singing school; but we have heard nothing of new compositions after his return, nor any thing more concerning him, except that he died at Paris in 1800.

PICCININI, ALESSANDRO, of Bologna, lived about the year 1570, and was in the service of the duke of Ferrara in 1594. He is author of a treatise on the tablature of the lute, which was in great estimation. In this work, we find the origin of the *theorbo* and *pandore*. He pretends to have been the inventor of the *arch-lute*.

PICCILOLO, in *Commerce*, a money of account in the island of Sicily. Thus, a taro contains 2 carlini, 15 ponti, or 120 piccioli; a carlino, 10 grani; a pon o, 8 piccioli; and a grano, 6 piccioli.

PICCITONO, PARDE ANGELO DA, in *Biography*, author of a book entitled "Fior Angelico di Musica," published at Venice in 1547; a work which, however difficult to find at present, is, from its dulness and pedantry, still more difficult to read.

PICCOLOMINI, ALESSANDRO, a learned Italian, was born at Sienna in 1508. He passed the early part of his life in his native place, and was a member of the celebrated academy of *Degli Intronati*, in which he bore the name of "Stordito." He is supposed to have been in that city at the time of the visit of the emperor Charles V. in 1536, when his comedy, entitled "Amor Costante," was recited before that prince. He wrote two other comedies, "L'Alessandro" and "L'Ortenzio," and translated the 13th book of Ovid's *Metamorphosis*, and the 6th book of Virgil's *Æneid*, into Italian verse, and printed a collection of 100 sonnets. About the year 1540 he went to Padua, where he was aggregated to the academy *Degli Inflammati*, and engaged to read lectures in it on moral philosophy. He wrote books also on morals, on philosophy, and astronomy; and by order of duke Francesco de Medici, he wrote a book on the reformation of the calendar undertaken by pope Gregory XIII. He resided several years at Padua and Rome, and at an advanced age retired to Sienna, where he possessed a villa and a fine garden. In 1574 Gregory nominated him to the titular archbishopric of Patras, and made him coadjutor of the archbishop of Sienna. He died in 1578, and was interred in the cathedral of that city.

PICE, in *Commerce*, a money of account and copper coin in the East Indies. At Calcutta and in Bengal, 12 pice = 1 anna, and 16 annas = 1 current rupee. See **RUPEE**.

The double and single pice are copper coins, with a mixture of tin or lead at Bombay, the single pice being 4 reas, and the double pice or fudda being 8 reas, the rea being $\frac{1}{16}$ th of the quarter, and the quarter $\frac{1}{4}$ th of the rupee. At Anjengo, on the Malabar coast, accounts are kept in fanams, pice, and budgerooks: a fanam being = 12 pice, or 16 vis, and 1 pice = 4 budgerooks: a silver rupee is worth 7 old fanams, or 6 new ones, called galloa fanams. All these are real coins. At Scindy the coins are silver rupees of 16 annas or 48 copper pice. At Surat, accounts are kept in rupees of 16 annas or 64 pice. Here are also

pezas or pice of copper or lead, 64 of which are reckoned to 1 silver rupee. Sixty padens, a sort of bitter almonds from Persia, pass for 1 pice.

PICE is also a weight in the East Indies. See **MAUND**.

PICENDACA, in *Ancient Geography*, a town of India, in the interior of the country belonging to the people called Arvari. Ptolemy.

PICENTES, a people of Italy, inhabitants of Picenum, who were originally Sabines. Strabo says that they took their name from the word *picus*, which they followed whilst they were going to establish themselves in their new country. See **PICENUM**.

PICENTIA, BICENZA, a town of Italy, and capital of the Picentini. It was situated in the interior of the country: and Pliny reports, that the inhabitants were driven from it on account of their having taken part with Hannibal. It continues to subsist under the same name; though at present there are merely traces of it remaining.

PICENTINI, a people of Italy, who were descended from the Picentes, and whose immediate origin is very uncertain; they were settled towards the west on the sea-coast.

PICENTINUM, PEZENTINUM, or Pefcentinum, a town of Pannonia, upon the route from Æmona to Sirmium, between Inicerum and Leuconum, according to Antonine's Itinerary.

PICENUM, a country of Italy, on the Adriatic gulf; extending from the Æfis, towards the N.W., as far as Truentus. It was bounded to the N. by the Æfis, to the S. by the Truentus, to the E. by the Adriatic sea, to the W. by a small part of Umbria and mount Fiscelus, and some other mountains which separated it from the country of the Sabines. Its principal rivers were the Æfis, the Misios, the Potentia, the Timna, and the Truentus. The most noted places were, commencing from the N., Ancona, Auximum, Firmum, and Asculum. The origin of its name has been given under Picentes. Eusebius and Servius, however, give the name of Picus to the chief of the colony.

PICHANA, in *Geography*, a town of South America, in the province of Cordova; 130 miles N.W. of Cordova.

PICHINCA, a mountain of Peru, in the jurisdiction of Piura, and bishopric of Truxillo, whose height is said to be 2432 toises above the level of the sea. M. Von Humboldt was twice at the mouth of the crater of this mountain; no one but Condamine having ever reached it before. From the edge of the crater, he says, rise three peaks, which are free from snow, as it is continually melted by the ascending vapour. At the summit of these is a rock that projects over the precipice, and from which he made his observations. The rock is about twelve feet long by six broad, and strongly agitated by frequent shocks, of which he counted eighteen in less than half an hour. On this he lay on his belly, that he might the better examine the bottom of the crater. The mouth of the volcano forms a circular hole, near a league in circumference, the perpendicular edges of which are covered with snow on the top. The inside is of a deep black; but the abyss is so vast, that the summits of several mountains may be distinguished in it. Their tops seemed to be six hundred yards below his station; and he has no doubt but the bottom of the crater is on a level with the city of Quito, which the mountain overlooks. Condamine found it extinct, and even covered with snow: but M. Humboldt found it burning. On his second visit, being furnished with instruments, he found the diameter of the crater to be 1600 yards, whereas that of

Vesuvius is but 670. The height of the mountain is 5280 yards.

PICHINCHAS, a town of South America, in the province of Quito; 15 miles N.E. of Quito.

PICHMANSKOL, a town of Russia, in the government of Olonetz, on the lake Latcha; 32 miles S.S.W. of Kargapol.

PICICITLI, in *Ornithology*, the name of a bird in the Spanish West Indies, described by Nieremberg. Its head and neck are black, and its whole body grey; it is a small bird, and makes its appearance in Mexico after the rainy seasons; it is a bird of passage, and it is not known where it breeds. See *PIRA Cristata*.

PICIERNO, in *Geography*, a town of Naples, in the province of Basilicata; eight miles W.N.W. of Potenza.

PICIOTTI, a river of Naples, which runs into the sea, 15 miles S.E. of Reggio.

PICK, a river of Upper Canada, which runs into lake Superior, N. lat. $48^{\circ} 28'$. W. long. $86^{\circ} 4'$.—Also, a small island, in the N. part of lake Superior. N. lat. $48^{\circ} 31'$. W. long. $86^{\circ} 28'$.

PICK, among *Miners*, is a tool which they use to cut down the cliffs and rocks of stone to make passages in the earth; and which is also used in digging canals.

PICK-Axe, in the *Military Art*, a tool carried by the pioneers to dig up ground that is too hard for the spade; they are of great use for mending the ways, and in fortifications.

PICKS, Ear. See *EAR-picks*.

PICKAGE, or **PICCAGE**, *Piccagium*, an ancient custom, or duty, paid at fairs and markets, for breaking the ground, and pitching up stalls, or standings.

This profit of pickage was usually given, or granted, in charters for holding a fair or market.

PICKAWAY, in *Geography*, a county in the state of Ohio, containing, in 1810, 10 towns and 7124 inhabitants.

—Also, a town in the said county, of the same name, containing 1598 inhabitants.

PICKEERING, or **PICKEROONING**. See **PICQUEERING**.

PICKER, or **HORSE-PICKER**, in the *Manege*, an iron instrument five or six inches long, bent or crooked on one side, and flat and pointed on the other. It is used by grooms to cleanse the inside of the horses feet, and to pick out the earth, sand, or small stones that get into them.

PICKERELL, in *Ichthyology*, an English name used by some authors for the jack or pike.

PICKERING, in *Geography*, a market-town in the west division of the wapentake of Pickering-Lythe, and North Riding of Yorkshire, England, is pleasantly seated on an eminence, surrounded by the lofty mountains of Blakemore, at the distance of 26 miles from York, and 225 from London. It is a town of very remote antiquity. It seems formerly to have enjoyed the privileges of a borough, and undoubtedly sent members more than once to parliament. How it lost this right is unknown; but it was most probably through neglect. The market day here is on Monday weekly; and there are besides four annual fairs for horned cattle, horses, and sheep. Pickering is an honour belonging to the duchy of Lancaster, and possesses a jurisdiction over several of the neighbouring villages, lying within its boundaries. Here are, therefore, held the courts of the honour, and also the petty sessions for the west division of the wapentake.

In the parliamentary returns of 1811, the houses in this town are estimated at 540 in number, and the inhabitants at 2332. The former are arranged chiefly in one long straggling

street, which offers no edifice worthy of notice, except the church, an ancient and spacious structure, adorned with a lofty spire. Here are three meeting-houses appropriated to the public worship of Quakers, Presbyterians, and Methodists. Its western extremity, however, is rendered interesting by the remains of a strong castle, which occupies the brow of a hill overlooking the town, and commanding a delightful view of the vale of Pickering. The date of the foundation of this fortress is uncertain, but it appears from Domesday book to have belonged to Morcar, earl of Northumberland, in the time of Edward the Confessor. In the beginning of the reign of Henry III. the custody of it was committed to William, lord Dacre, high sheriff of the county; but this nobleman had only retained it two or three years, when it was bestowed by the monarch on his own son, Edmund, earl of Lancaster, whose successor, Thomas, forfeited it to the crown by rebellion. His descendants, however, afterwards recovered it; and it consequently came by marriage into the possession of the celebrated John of Gaunt, duke of Lancaster and king of Castile. What became of it after his death is unknown; but in the reign of queen Elizabeth we find it once more possessed by the crown; and in the time of the civil wars, in the seventeenth century, it is recorded to have stood a long siege against a party of the parliamentary forces sent to reduce it. Beauties of England and Wales, vol. xvi., by John Bigland.

PICKERING, a township in the East Riding of the county of York, in Upper Canada, between Whitby and Scarborough, and parting lake Ontario.

PICKERSGILL COVE, a harbour within Christmas Sound, on the S. coast of Terra del Fuego, at the S. extremity of South America.

PICKERSGILL Harbour, a port of New Zealand, on the S. shore of Dusky bay. S. lat. $45^{\circ} 47'$. E. long. $166^{\circ} 18'$.

PICKERSGILL Island, a small island in the South Atlantic sea, near the S. coast of the island of Georgia, so called after the name of captain Cook's third lieutenant. S. lat. $54^{\circ} 47'$. W. long. $36^{\circ} 42'$.

PICKERSVILLE, the chief town of Washington district, in South Carolina; 771 miles from Philadelphia.

PICKET, **PICQUET**, or **Piquet**, in *Fortification*, a stake sharp at one end, and usually shod with iron; used in laying out the ground, to mark the several measures and angles thereof.

There are also larger pickets, driven into the earth to hold together fascines, or faggots, in any work cast up in halts.

PICKETS are also stakes driven into the ground by the tents of the horse, in camp, to tie their horses to; and before the tents of the foot, where they rest their muskets, or pikes about them, in a ring.

The picket was a corporal punishment, chiefly used by the cavalry and artillery, and in the former often inflicted by order of the commanding officer, without the sentence of a court-martial. The mode of inflicting it was this: a long post being driven into the ground, the delinquent was ordered to mount a stool near it, when his right hand was fastened to a hook in the post by a noose round his wrist, drawn up as high as it could be stretched; a stump, of the height of the stool, with its end cut to a round and blunt point, was then driven into the ground near the post before-mentioned, and the stool being taken away, the bare heel of the sufferer was made to rest upon the stump, which, though it did not break the skin, put him to great torture: the only mitigation he could obtain was by resting his weight on his wrist, the pain of which soon became intolerable. Soldiers were frequently sentenced to stand on the picket

for

for a quarter of an hour. This, like the riding of the wooden horse, has been for some time left off, as it lamed and ruptured many soldiers. See *WOODEN HORSE*.

PICKETS are also stakes with notches toward the top, to which are fastened the cordages of tents. Thus, to plant the picket, is to encamp.

PICKET, in *Gaming*. See **PICQUET**.

PICKET, *Watching*, in *Ornithology*. See **ORIOULUS NIDIPENDULUS**.

PICKLE, a brine, or liquor, ordinarily composed of salt, vinegar, &c. sometimes with the addition of spices; in which meats, fruits, and other things, are preserved and seasoned.

PICKLE is also used substantively, for a fruit, root, leaf, or other vegetable matter, prepared in pickle, to be used by way of sauce, &c. See **SALLET**, &c.

They pickle artichokes, mushrooms, ashen-keys, barberies, asparagus, beans, onions, &c. Broom-buds, capers, and olives, are pickled with oil and vinegar.

PICKLE, in *Agriculture*, a sort of brine or liquor used for steeping grain, to preserve it from disease, insects, and vermin.

A great number of different compositions have been at different times employed as steeps or pickles, for freeing grain from disease; but those which are the most in use at present are such as are described below, though very strong solutions of common salt, and other similar substances, have been often employed.

Pickle Arsenic.—Much advantage is said to have been found by Mr. Young, from the use of half a hoghead of strong lixivium of wood-ashes, put in a cast-iron boiler, with seven pounds of common salt, and one pound of arsenic boiled well, and kept in the boiler for use when cold. And which, without the salt, was employed with benefit by Mr. Andrews.

Pickle Salt.—This is prepared, according to Mr. Summerville, sometimes with plain water, into which common kitchen salt is put, till it is of such a strength as to float an egg. In many cases, however, sea-water is used, and salt added to it, till it will also carry an egg. The advantage of using sea-water is, that less salt is required. The pickle, thus prepared, is put into a large open vessel, that will hold perhaps 30 or 40 gallons: the wheat is then poured into it, in the quantity of from a bushel, to two bushels at a time, and well stirred round, either with a broom or a stick; during the stirring, the light grains rise to the surface and are skimmed off; the vessel is then lifted up, and the contents poured into another of equal dimensions, upon the mouth of which a sieve is placed; the sieve retains the grain, and suffers the pickle to pass through it into the vessel beneath. The same quantity of wheat is again put into the pickle, and the same process repeated, till the whole has been washed and pickled; and progressively as it is taken out of the water, some new flaked lime is sifted upon it. The whole is then carefully mixed up with a wooden shovel, and frequently turned over, till it attain a sufficient degree of dryness, in which state it is committed to the earth without any further preparation or management.

Pickle Urine.—This is prepared in this way, according to the same writer: a quantity of urine, in as stale a state as possible, is put into a vessel, in the same manner as for the salt pickle, into which the grain is put and well stirred. The contents are then poured through a sieve, and the process continued till the whole of the wheat intended to be sown is moistened. It is then sprinkled with lime, as in the former case, and committed to the earth. It is, however, added, that in many cases, instead of mixing the whole of

the grain with the urine, it is common to spread the wheat upon the barn-floor, and sprinkle the urine upon it, either with a watering-pan or a kind of brush made of straw: when it is sufficiently moistened, lime is made use of as before, and the grain sown.

Pickle Italian.—This is that recommended by J. B. Scandella, an Italian physician, which is prepared in this manner: Take of nitre, three pounds; alum, one pound; vitriol, six ounces; verdigris, three ounces; wood-ashes, well sifted, six pounds; boil the whole in a copper with five pails of water for an hour, then remove them from the fire, and pour them into a large vessel; then add sixteen pails of water, in which half a bushel of quick-lime has been previously dissolved; mix the whole intimately, and allow them to stand still till they are quite cold. In this steep, two bushels and a half of wheat are to be plunged, and left for about six hours, stirring it up frequently with a wooden shovel, and skimming off what rises to the surface: the wheat is then to be withdrawn, and spread out till it is dry enough for sowing. The process is thus to be continued until the whole quantity of seed intended to be sown is pickled. The above steep is generally sufficient for preparing about twenty-four bushels of wheat.

And on these different pickles or steeps the ingenious writer has made several pertinent reflections. On the first he remarks, that as far as his own observation, aided by the testimony of the most respectable farmers, can be depended upon, it has never been known to fail in a single instance, where judiciously applied; that is to say, it has always prevented the crop from suffering by smut. But though it has answered this purpose most effectually, and the proofs in favour of it are too numerous to be disputed, there is little doubt that, under certain circumstances, it may be highly injurious to the crop. And that while the grain, steeped in this pickle, continues in a moist state, it may be kept for any length of time, without much injury to its vegetative powers; a circumstance of no small consequence, as it not unfrequently happens that after the grain has been pickled, and made ready for sowing, a sudden fall of rain prevents it from being put into the earth for several days, perhaps weeks. But though the pickle is thus harmless while the grain continues in a moist state, repeated trials convince him that it is quite otherwise when well dried, and exposed to a certain degree of heat. He does not hazard this merely as an opinion, but speaks from conviction, when he says that if wheat, which has undergone this preparation, and has had lime in a very active state mixed with it, is sown early in the autumn (as in August), upon dry warm land, and no rain falls for a considerable time after, a thing by no means uncommon at that season of the year, a great proportion of the grain will either be entirely destroyed, or materially injured, by the dry caustic crust with which it is surrounded. The mischief in this case is certainly done by the action of the lime, and in many instances is, he supposes, very considerable. But in order to avoid this inconvenience, the writer states, that from much inquiry, as well as numerous trials of his own, he is perfectly satisfied that the most valuable part of this preparation consists in immersing the wheat in the brine, and that the lime is only added afterwards as an absorbent to dry up the superfluous part of the moisture, and make the grains separate, and sow more readily. If this is admitted, and it certainly is the case, it will be extremely easy to reap the whole benefit of the salt pickle, without any of its defects, merely by substituting some other article in the place of lime; and for that purpose nothing seems better calculated than powdered chalk, or common whiteness. The former is known, in its unburnt state,

state, to be entirely destitute of any caustic or corrosive quality; and the latter consists of burnt limestone, which has been completely saturated with moisture, and afterwards dried, by which process its activity is destroyed. Both of these articles can be obtained in sufficient quantity, in most situations; and as neither of them are expensive, they will be found good substitutes for lime; and if properly managed, will answer every purpose that can be expected from it, without the smallest degree of risk.

It is asserted, in respect to the urine pickle, that there is no article at present employed that requires to be used with more circumspection than this; nor is there any where the risk or loss attending its use has a chance of being so great. He is ready to admit, that where the urine is sufficiently stale, and the grain properly moistened with it, every insect or animalcule contained therein will be completely destroyed; but to counterbalance this, he has to state that as yet there has been no test established to ascertain the necessary degree of staleness: and as it is known that urine, which is not stale, will not destroy vermin, there is an absolute certainty, if it is used in that state, it will be of no service; and that, on the other hand, when urine is completely stale, it abounds with volatile alkali, which, in its naked state, is known to be hurtful, when applied either to seeds or plants; but when united with lime, it then forms what is called caustic alkali, in which state its strength and dangerous qualities are very considerably increased. This compound, though an excellent manure when applied to the soil, and allowed to operate properly upon it before the crop is sown, is completely destructive both to seeds and plants, when brought into contact with them. When wheat, therefore, has been completely moistened with urine, and is afterwards mixed with quick-lime, the crust with which it is surrounded will be of the most acrid nature, and nothing but throwing the seed immediately into a tolerably moist soil can possibly save it from destruction. Accordingly it has often happened, when wheat pickled in this way has, by bad weather, or any other accident, been prevented from being sown even for a single night, nine-tenths of the seed have been known to perish. He has said, that nothing can save the seed thus cruised over from destruction, but sowing it instantly upon land containing a certain share of moisture. If the soil happens, however, to be of a warm nature, is very dry at the time of sowing, and the weather continue warm and dry for any considerable time afterwards, an immense deal of the seed will perish by the action of the pickle. And these objections to the urine pickle, which every man who is in the slightest degree acquainted with its chemical properties will readily understand, apply to those cases where the pickle has been most faithfully prepared and administered, and that is when the grain has been completely immersed in it. The other method, *viz.* that of laying the wheat upon the barn-floor, and sprinkling it with a wisp of straw dipped in the urine, is also liable to many objections. He has already hinted, that we have at present no test for ascertaining the necessary degree of staleness in urine: the want of this must always subject the use of it to very great uncertainty. But admitting that it were in all cases sufficiently stale, there is no possibility of applying it properly or equally, when the wheat is spread upon the floor: some of it will have more moisture than it requires, some will be very imperfectly moistened, and many of the grains will not be moistened at all. He need scarcely add what the consequences of such management will be. The part of the seed, which has got an over-dose, will be subjected to all the risks he has mentioned, from the caustic quality of the urine and lime; and the remaining part, which has been either imperfectly

moistened, or not moistened at all, will, by the vermin not being destroyed, produce blighted or smutted ears. When speaking of the salt pickle, he has said, that if powdered chalk or common whitening are used, it will destroy the insects as effectually as lime, and that without the least risk to the grain, and has accordingly recommended it to be prepared in that way. The urine pickle he decidedly condemns, as it is in every point of view liable to insuperable objections: for whether the urine is used singly, or in conjunction with lime, great mischief may be done by it, if the wheat is either prevented by any accident from being sown even for a single night, or if it is sown upon dry land, and the weather continues warm, and no rain falls for a considerable time afterwards; but if the urine pickle is ever had recourse to, it will certainly be much milder, if chalk or whitening be employed as absorbents in place of lime, than under other circumstances.

But he is fully sensible that much opposition will be made to the doctrine here laid down concerning these pickles, especially by those who have been long accustomed to the use of them; and who, without knowing the risk with which they are attended, have generally ascribed the failure or deficiency of their wheat crop to other causes. But the ideas here held forth are by no means the offspring of conjecture, or a warm imagination. Careful trials have been made of each, under almost every variety of circumstances that can occur, with this result;—that though, in a few fortunate cases, both the salt and the urine pickles may be used without any seeming loss or inconvenience, yet in a majority of all the instances in which they are employed, more or less of the seed perishes from their effects. He has, for several years past, made trials of both pickles upon a given number of seeds, sown at different periods of the season, and under different circumstances of heat and moisture, and he has uniformly found that when wheat, pickled with salt and lime, was sown either upon ground containing a moderate share of moisture, or had a slight shower soon after it was sown, scarcely one grain in ten perished; whereas, when it was sown upon warm dry land, and no rain fell for perhaps two or three weeks afterward, nearly a third of the seed never vegetated. And that when the urine pickle was used, even under the most fortunate circumstances, two grains out of ten, or one-fifth part of the whole, was generally the least failure that happened, even when it was sown immediately after being pickled: but in cases when it was kept a night or two in the pickle, nine-tenths of the seed have been known to perish; and when sown upon very dry land, and much dry warm weather followed, the loss has also been very great. These trials having been made with a given number of grains, the writer was enabled to ascertain, with perfect accuracy, the proportion which perished in each experiment.

But with regard to the last sort, or Italian pickle, it has not hitherto been sufficiently in use fully to ascertain in what respects it may be injurious, or beneficial, when made use of in preparing feed corn for being put into the ground. From the nature of the different ingredients, it would, however, seem to be a preparation of an active nature, and which should be employed with caution, till more full experience has shewn its effects and advantages.

PICKLE is also a term sometimes applied to the grains of wheat, in discriminating its quality; thus we have a *lean* and a *hungry* pickle, &c.

PICKLED FISH. See FISH.

PICKLING of Grain, in *Agriculture*, the art of steeping it in pickles, in order to preserve it, and prevent the crops from being diseased.

It is sufficiently plain, from what has been observed in respect to pickles, that they are liquors of a very active nature, and which must be employed with considerable care, and nice attention to the circumstances of the weather and state of the land; as, without this, much injury and disadvantage, instead of benefit, may be the result. The length of time for effecting the purpose, in the safest manner, must also be had in the mind of the farmer; as the steeping of grain from twenty to twenty-four hours in solutions of wood-ashes and arsenic, as well as in lime-water, gave clean crops from extremely smutty seed; while the retaining it in these mixtures only a short time had but a comparatively trifling effect. In all cases, in using these pickles, great attention should likewise be paid to having the grain as equally as possible imbibed and impregnated with the liquors, as in this way the most beneficial effects must be produced.

But whatever danger there may be in pickling feed corn, for the purpose of preventing its being affected with the smut, it is a practice that is seldom or ever neglected in the northern parts of England, and in Scotland, without the farmers in these parts suffering from such omissions.

PICKOUAGAMIS, in *Geography*, a river of Canada, which runs from lake Shabamouhan to lake St. John.

PICLE, PICTELLUM, a small parcel of land inclosed with a hedge; a little close. This word seems to come from the Italian *picciola*, i. e. *parvus*; and in some parts of England is called *pightel*.

PICO, GIOVANNI, of Mirandola, in *Biography*, one of the most extraordinary persons of his time, surnamed the Phoenix, was the third son of Gianfrancesco Pico, prince of Mirandola, and Concordia. He was born in 1463, and almost from his childhood displayed an eager attachment to literature. At the age of 14 he was sent to Bologna to study canon law, but after spending two years there, he set out to visit the most celebrated schools in Italy and France. He went to Ferrara, where he was kindly received by his relation Duke Hercules I., and studied under Batista Guarino. He had a great readiness in acquiring languages, and is said to have thoroughly understood twenty-two by the time he was eighteen years of age. This is probably an exaggeration. After he had employed seven years in his academical tour, he returned to Rome at the age of twenty-three. There he potted up 900 propositions appertaining to dialectics, morals, physics, mathematics, &c. offering to dispute with any antagonist whomsoever upon any one of them. This caused him to be looked upon with envy and jealousy, none daring to accept of his challenge. Thirteen of his propositions were however accused before the pope as contrary to sound doctrine. He published an elaborate defence of them addressed to Lorenzo de Medici, and after putting him to a considerable deal of trouble in justifying himself, he was acquitted of all blame. The effect of the anxiety produced by this business caused a total change in his course of life, and though young, rich, elegant in person and manners, and in some degree habituated to pleasure, he gave himself up to devotion, and confined his future studies to theological subjects. He fixed his abode in Florence, where he enjoyed the intimacy of several illustrious characters, among whom was Lorenzo de Medici, who testified his affection for him by calling him to a parting embrace on his death-bed. His high reputation caused him to be thought of for the cardinalate, but it does not appear that any steps were taken to advance him to that dignity. At this period he had a most enthusiastic desire to be useful, and he resolved to distribute all his property among the poor, and travel bare-footed through the world to preach the gospel. An early death, at the age of 32, put an end to his

projects. The writings of Pico display an acute genius, and a vast extent of learning, but they added very little to true science. His principal works are "Hexaplus, or an Explanation of the Six Days of Creation;" "Adversus Astrologiam Divinaticem;" *Epistolarum*, lib. viii.

PICO, GIANFRANCESCO, prince of Mirandola, nephew of the preceding, being son of his brother Galeotto, was born in 1470. He studied at Ferrara, and manifested, like his uncle, an early attachment to literature. After the death of his father, he succeeded to the sovereignty of Mirandola, an elevation which proved the source of many troubles. His brother Lodovico, who had married a daughter of general Trivulzi, was his competitor, and by the assistance of a third brother, he expelled Gianfrancesco in 1502. He was restored by the arms of pope Julius II. in 1511, but was again dethroned, and on the 15th of October, 1533, Galeotto, nephew of Lodovico, with a band of armed men surprised Mirandola, and entering the chamber of Gianfrancesco, put him and one of his sons to death, and then imprisoned his wife and younger son. He was probably much better fitted for a private than a public station. In the midst of all the changes of fortune, religion and letters were his chief solace. He was in habits of correspondence with all the eminent literary characters of his time, many of whom held him in the highest estimation. He was author of many works, but that by which he is best known is a life of his uncle, containing much curious information respecting that extraordinary man. He also composed a life and apology of the famous Savonarola.

PICO, or the PEAK, in *Geography*, one of the Azores, which derives its name from a high mountain, terminating in a peak. This volcanic mountain is by some reported to be equal to the peak of Teneriffe in height. Mr. Adanson, who visited these islands in his return from Senegal in 1753, says that the peak is about half a league in perpendicular altitude, which, allowing the French league to be 2450 toises, would give a moderate height, not exceeding 7350 feet. The peak would form a very convenient first meridian, from which to reckon the longitude. The dimensions of the island are about 30 British miles in length, and 10 in breadth. The chief places are Pico, Lagoas, Santa Cruz, San Sebastian, Pasquin, San Rocko, Playa, and Magdalena. The island is productive; its cattle are numerous, of various kinds, and excellent; its wine is highly commended; and it furnishes a considerable quantity and variety of wood, particularly the cedar and teixo, which is solid and hard as iron, and veined when finely polished. The inhabitants live wholly on the produce of their own island in plenty and comfort. Pico carries on a considerable trade in wine, which seems to be sold as Canary. N. lat. 38° 30'. W. long. 28° 16'.

Pico, a mountain of Spain, on the confines of New and Old Castile, and Estremadura.

Pico, or *Puerto de Pico*, a town of Spain, in Old Castile, on a mountain, near the source of the Tormes.

Pico *Sacro*, a mountain of Spain, in Galicia; nine miles S. of Santiago.

Pico *Teneriffe*, a mountain of Barbadoes; one mile S. of Cuckold's point.

Pico *el Teja*, a town of Spain, in Old Castile; 20 miles W.S.W. of Segorbe.

Pico *d'Urbino*, a mountain of Spain, in Old Castile; 12 miles S. of Calzada.

PICOLATA, a fortress of East Florida, on the river St. John; 27 miles from St. Augustine.

PICOLET POINT, a point on the N. side of the island of St. Domingo, that forms the W. boundary of the bay which

which sets up to cape Francois. Under its cannon ships have been secured in time of war.

PICOLO, a town of Italy, in Friuli; six miles S. of Udina.

PICOLOS, the name of an ancient Prussian idol, to which human sacrifice was offered. See POTRIMPOS.

PICOSA, or PISANA, in *Geography*, mountains of the coast of Peru, extending about seven leagues between Colamahe river and Salango island, S. of the equator, and serving for the direction of mariners.

PICOTA, a name given by some authors to a distemper which they describe as consisting wholly in an eruption of a number of very minute pimples upon the skin, all over the body; it is attended with no danger, unless they are struck in.

PICOY, in *Geography*, a town of Peru, in the diocese of Guamanga, on a river of the same name, which runs into the Xauxa, 20 miles N. of Guanca Velica.

PICQUEERING, or *Pickerooning*, a little flying war or skirmish, which the soldiers make when detached from their bodies to pillage, or before a main battle begins.

PICQUET, or PICKET, a celebrated game at cards, much in use throughout the polite world.

It is played between two persons, with only thirty-two cards; all the duces, threes, fours, fives, and sixes, being set aside.

In reckoning, at this game, every card goes for the number it bears, as a ten for ten; only all court-cards go for ten, and the ace for eleven: and the usual game is one hundred up. In playing, the ace wins the king, the king the queen, and so down. Twelve cards are dealt around, usually by two and two; which done, those that remain are laid in the middle. If one of the gamesters finds he has not a court card in his hand, he is to declare he has *carte blanche*, and tell how many cards he will lay out, and desire the other to discard, that he may shew his game, and satisfy his antagonist, that the *carte blanche* is real; for which he reckons ten.

Each person *discards*, *i. e.* lays aside a certain number of his cards, and takes in a like number from the stock. The first, of the eight cards, may take three, four, or five; the dealer all the remainder, if he pleases.

After discarding, the eldest hand examines what suit he has most cards of; and, reckoning how many points he has in that suit, if the other have not so many in that, or any other suit, he tells one for every ten of that suit. He who thus reckons most is said to win the *point*.

The point being over, each examines what *sequences* he has of the same suit; *viz.* how many tierces, or sequences of three; quarts, or fours; quintes, or fives; fixiemes, or sixes, &c. For a tierce they reckon three points, for a quarte four, for a quinte fifteen, and for a fixieme sixteen, &c. And the several sequences are distinguished in dignity by the cards they begin from: thus, ace, king, and queen, are called *tierce major*; king, queen, and knave, *tierce to a king*; knave, ten, and nine, *tierce to a knave*, &c. and the best tierce, quarte, or quinte, *i. e.* that which takes its descent from the best card, prevails; so as to make all the others in that hand good, and destroy all those in the other hand. In like manner, a quarte in one hand sets aside a tierce in the other.

The sequences over, they proceed to examine how many aces, kings, queens, knaves, and tens, each holds; reckoning for every three, of any sort, three; but here too, as in sequences, he that with the same number of threes has one that is higher than any the other has, *e. gr.* three aces,

has all his other made good hereby, and his adversary's are all set aside. But four of any sort, which is called a *quatorze*, always set aside three.

All the game in hand being thus reckoned, the eldest proceeds to play, reckoning one for every card he plays above a nine, and the other follows him in the suit: and the highest card of the suit wins the trick. Note, unless a trick be won with a card above a nine (except the last trick), nothing is reckoned for it: though the trick serves afterwards toward winning the cards; and that he who plays last does not reckon for his cards, unless he win the trick.

The cards being played out, he that has most tricks reckons ten for *winning the cards*. If they have tricks alike, neither reckons any thing. The deal being finished, and each having marked up his game, they proceed to deal again as before; cutting afresh each time for the deal.

If both parties be within a few points of being up, the *carte blanche* is the first thing that reckons; then the point, then the sequences, then the quatorzes or threes, then the tenth cards.

He that can reckon thirty in hand by *carte blanche*, points, quintes, &c. without playing, before the other has reckoned any thing, reckons ninety for them; and this is called a *re-pique*. If he reckons above thirty, he reckons so many above ninety. If he can make up thirty, part in hand, and part in play, before the other has told any thing, he reckons for them sixty. And this is called a *pique*. Whence the name of the game.

He that wins all the tricks instead of ten, which is his right, for winning the cards, reckons forty; and this is called a *capot*.

This game has, in some cafes, been the object of mathematical computation.

Thus M. de Moivre has proposed and solved the following problems:

1. To find at picquet the probability which the dealer has for taking one ace or more in three cards, he having none in his hand. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more.

2. To find at picquet the probability which the eldest has of taking an ace or more in five cards, he having no ace in his hand. Answer; 232 to 91, or 5 to 2, nearly.

3. To find at picquet the probability which the eldest hand has of taking an ace and a king in five cards, he having none in his hand. Answer; the odds against the eldest hand taking an ace and a king are 331 to 315, or 21 to 20 nearly.

4. To find at picquet the probability of having twelve cards dealt to, without king, queen, or knave; which case is commonly called *cartes blanches*. Answer; the odds against *cartes blanches* are 1791 to 1 nearly.

5. To find how many different sets, essentially different from one another, one may have at picquet before taking in. Answer; 28,967,278. This number falls short of the sum of all the distinct combinations, whereby twelve cards may be taken out of 32, this number being 225,792,840; but it ought to be considered, that in that number several sets of the same import, but differing in suit, might be taken, which would not introduce an essential difference among the sets.

M. De Moivre also gives some observations on this game which he had from an experienced player. See *Doctrine of Chances*, p. 179, &c.

M. de Monmort has also treated of picquet in his *Analyse des jeux de Hazard*, p. 162.

PICQUET Guard. See **GUARD.**

PICQUET-Berg, in *Geography*, a division of the district of Stellenbosch and Drakenstein in southern Africa, near the Cape of Good Hope. It terminates the plain of the Four-and-twenty rivers to the northward. Here, besides corn and fruit, the inhabitants rear horses, horned cattle, and sheep. And from hence also is sent to the Cape market a considerable quantity of tobacco, which has the reputation of being of the best quality that southern Africa produces.

PICQUIGNY, a town of France, in the department of the Somme, and chief place of a canton, in the district of Amiens. The place contains 1253, and the canton 14,125 inhabitants, on a territory of 202½ kilometres, in 22 communes.

PICRA, HIERA. See **HIERA.**

PICRAMNIA, in *Botany*, so named by Swartz from πικρα, bitter, and βρωμος, a shrub, on account of the great bitterness of every part of the plant. Swartz. Prodr. 27. Fl. Ind. Occ. 217. Schreb. 687. Willd. Sp. Pl. v. 4. 761. Ait. Hort. Kew. v. 5. 384.—Class and order, *Dioecia Pentandria*. Nat. Ord. uncertain; perhaps akin to *Rhus*.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in three or five deep, lanceolate, erect segments. *Cor.* Petals three or five, lanceolate, somewhat spreading, longer than the calyx. *Stam.* Filaments three or five, awl-shaped, approximated at the base, erect, longer than the corolla; anthers ovate, two-lobed.

Female, on a different plant, *Cal.* as in the male, permanent. *Cor.* as in the male. *Pist.* Germen (superior?) oblong, rather compressed; styles two, short, recurved, permanent; stigmas simple, acute. *Peric.* Berry roundish-ovate, of two cells. *Seeds* two in each cell, ovate-oblong.

Eff. Ch. Male, Calyx in three or five deep segments. Petals three or five. Stamens three or five.

Female, Calyx and Corolla like the male. Styles two. Berry of two cells. Seeds two in each cell.

Obf. The berry is said to have sometimes, though very rarely, three cells, and solitary seeds.

1. *P. Antidesma.* Ash-leaved Picramnia. (*Berberis fruticosa racemosa, fraxini folio alato, fructu nigro dipyrreno*; Sloane Jam. v. 2. 101. t. 208. f. 2. *Antidesma*; Browne Jam. 123.)—Clusters slender, pendulous. Stamens three. Styles recurved.—Native of Jamaica and Hispaniola; brought to Kew by admiral Bligh's ship in 1793, but it has not yet blossomed. The stem is nine or ten feet high, according to Sloane, as thick as a man's arm, smoothish. Leaves scattered, pinnate, of about seven smooth, elliptical, nearly entire, leaflets. Clusters long, loose, of numerous little yellowish-white flowers. Berries the size of gooseberries, at first red, then black, ripe in November. The negroes esteem this shrub antisyphilitic, and use its infusion as a remedy for the colic.

We quote Willdenow after the Hort. Kew. without having that part of his work at hand, so that we know not whether he describes, as the specific character seems to imply, more than one species.

PICRIA, so called by Loureiro, from πικρα, bitterness, on account of the flavour of every part of the plant. Lour. Cochinch. 392.—Class and order, *Didynamia Angiospermia*, or rather perhaps *Diandria Monogynia*. Nat. Ord. *Personata*, Linn. *Scrophularia*, Juss.

Gen. Ch. *Cal.* Perianth superior, four-leaved, deciduous; two of the leaves ovate, flat, longer than the corolla; two others alternate, linear, shorter. *Cor.* tubular, ringent; tube contracted in the middle; upper lip spatulate, emarginate; lower broadest, in three rounded equal segments.

Stam. Filaments four; the two longest erect, separately sheathed with papillary tubes; their anthers of one cell, curved, distant; two shorter inflexed; their anthers connected together, each of two cells. *Pist.* Germen ovate; style the length of the corolla; stigmas two, lanceolate, erect. *Peric.* Berry ovate, inferior, of two cells. *Seeds* very numerous, roundish.

Eff. Ch. Calyx of four leaves. Corolla ringent. Berry inferior, of two cells.

1. *P. Fel-terra.* Cultivated in the gardens of China and Cochinchina. The leaves are esteemed for their aperient, sudorific, diuretic, and emmenagogue properties; and used in incipient dropsy, intermittent fevers, colics, and various suppressions. The stems are numerous, herbaceous, perennial, eighteen inches high, erect, square, branched. Leaves opposite, ovate, serrated, rough, but not hairy. Flowers pale red, crowded, stalked, axillary, and terminal.—Such is Loureiro's description. We find no notice of this genus in other writers; yet it must be presumed that a plant so generally cultivated, and of so good report as to its medical uses, can hardly have escaped the notice of botanical travellers. Many points indicate an affinity to *Gratiola*, but the fruit being a berry, and inferior, is foreign to that genus, nor can we, by any probable conjecture, reduce Loureiro's plant to any other with which we are acquainted.

PICRIDIDIUM, so called from its bitterness, a genus established by Desfontaines in his *Flora Atlantica*, the only two species of which, mentioned by that able writer, are *P. tingitanum* and *P. vulgare*. The first is *Scorzonera tingitana*, the other *Scorzonera picroides*, of Linnæus. Both are removed by Willdenow to *Sonchus*, a measure adopted in the Prodr. Fl. Græc. v. 2. 126; nor can we trace any thing like an essential difference, in the character given by Desfontaines, to separate them from that genus, with which moreover they well accord in habit.

PICRIS, from πικρα, bitter, a name for the wild fucory, or some bitter herb of that family. It is well chosen for the present genus, inferior to few of its natural order in this respect. Linn. Gen. 399. Schreb. 526. Willd. Sp. Pl. v. 3. 1556. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 814. Prodr. Fl. Græc. Sibth. 131. Ait. Hort. Kew. v. 4. 447. Juss. 170. Lamarck Illustr. t. 648. Gærtn. t. 159. (Helmintia; Juss. 170. Willd. Sp. Pl. v. 3. 1607. Ait. Hort. Kew. v. 4. 461. Lamarck Illustr. t. 648. Gærtn. t. 159.)—Class and order, *Syngenesia Polygamia-æqualis*. Nat. Ord. *Compositæ semisifculosæ*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. Common calyx double; the outer of several flat, lax, converging scales; inner ovate, of many equal parallel scales. *Cor.* compound, imbricated, uniform, of numerous monopetalous, ligulate, linear, abrupt, five-toothed, perfect florets. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen to each floret nearly ovate; style the length of the stamens; stigmas two, reflexed. *Peric.* none, except the permanent calyx, finally reflexed. *Seeds* solitary, swelling, obtuse, transversely furrowed; down feathery, sessile or stalked. *Recept.* naked.

Eff. Ch. Receptacle naked. Calyx double; the inner equal; the outer lax. Down feathery. Seeds transversely furrowed.

Obf. The inner calyx is by no means imbricated. Its scales, or leaves, are parallel, close, all of equal length. The **HELMINTIA** of authors, see that article, consists of the first of our species only; its outer calyx has but five leaves, the inner about eight; and the seed-down is stalked. The habit

habit also is rather peculiar; but we are always on our guard against the unnecessary multiplication of genera, that inure to the most accurate observers.

1. *P. echioides*. Britfly Ox-tongue. Linn. Sp. Pl. 1114. Curt. Lond. fasc. 3. t. 51. Engl. Bot. t. 972. (*Helmintia echioides*; Willd. Sp. Pl. v. 3. 1607. *Buglossum luteum*; Ger. Em. 798.)—Outer calyx of five broad prickly leaves. Down stalked. Leaves wavy.—Native of banks and the borders of fields, especially on a clay soil, in England, France and Italy, flowering in June and July. The root is annual. Herb two or three feet high, branched, bright green, copiously beset with rigid pungent prickles, of which those on the disk of the leaves proceed each from a hard tubercle. Lower leaves lanceolate; upper heart-shaped and clasping the stem. Flowers rather large, of a bright golden yellow. The plant abounds with a bitter milky juice; yet Dr. Sibthorp found the leaves in use among the modern Athenians, either raw, as an ingredient of their salads, or boiled as a pot-herb.

2. *P. hieracioides*. Hawkweed Ox-tongue. Linn. Sp. Pl. 1114. Willd. n. 1. Ait. n. 1. Engl. Bot. t. 196. (*Hieracium asperum*; Ger. Em. 298.)—Stem rough. Outer calyx many-leaved, short, lax. Leaves lanceolate, wavy; the radical ones toothed. Down sessile.—Found about dry gravelly banks, and the borders of fields, in the north of Europe; not rare in the chalk or gravel counties of England; flowering in July and August. Root biennial. Herb corymbose and widely spreading, dark green, rough. Flowers yellow, with a broader corolla, but smaller calyx, than the former.

3. *P. japonica*. Japanese Ox-tongue. Thunb. Jap. 299. Willd. n. 2.—Stem hispid. Leaves sessile, lanceolate, hairy, toothed. Flowers paniced. Calyx hispid; the outer one erect.—Native of hills in Japan, flowering in April or May. Stem two feet high, hispid. Lower leaves a finger's length, somewhat stalked; upper shorter and sessile, alternate. Flowers yellow, paniced, on long, naked, hispid, compound stalks.

4. *P. aculeata*. Prickly Ox-tongue. Vahl Symb. v. 2. 89. Willd. n. 3.—Stem very prickly. Leaves elliptic-lanceolate, toothed. Flowers corymbose. Calyx hispid; the outermost lax.—Native of uncultivated hills in Barbary. Perennial. A foot high, rough all over with copious small rigid prickles. Vahl describes it as differing from *P. echioides* in the want of a five-leaved outer calyx; yet he says there is an outer calyx, only all the calyx-scales are linear-lanceolate. Such is the case with every species except *echioides*.

5. *P. pauciflora*. Few-flowered Ox-tongue. Willd. n. 4. Prodr. Fl. Græc. n. 1912.—Stem hairy. Leaves lanceolate, sessile, toothed. Flower-stalks elongated, swelling. Calyx hairy; the outermost lax.—Native of the south of France and of Greece. It was raised in Chelsea garden in 1788, as well as in that of the late Dr. Gwyn at Ipswich, from seeds given to the writer of this by M. Gerard. The root appears to be annual. Stem from eight to twenty-four inches high, more or less branched, spreading, rough with short bristly cloven-pointed hairs, as is all the herbage. Flowers yellow, of an ordinary hawkweed aspect, open in the morning only. Villars's figure of his *Hieracium pappo-leucum*, Dauph. t. 31, is a very tolerable representation of this plant, as Willdenow has likewise noted; but specimens from the author himself prove very different from our *Picris*.

6. *P. asplenoides*. Spleenwort-leaved Ox-tongue. Linn. Sp. Pl. 1115. Willd. n. 5. Vahl Symb. v. 2. 90. Prodr. Fl. Græc. n. 1913. Ait. n. 2. (*Leontodon muricatum*; L'Herit. Stirp. 173. t. 82. *Virea scabra*; Scop. Del. Insul. v. 2. 25. t. 13.)—Stem rough. Leaves oblong-

lanceolate, obtuse, sinuated. Flower-stalks elongated, swelling. Calyx rough; the outermost reflexed.—Native of the sandy sea-coast of Barbary. Perennial. Much larger than the last, with blunt, strongly sinuated, or pin-natifid, leaves; and some of the seed-down is stalked, which greatly invalidates the supposed character of *Helmintia*, as a distinct genus.

7. *P. ruderalis*. Rock Ox-tongue. Willd. n. 6.—Stem hispid. Leaves lanceolate, with fringe-like teeth. Flower-stalks and calyx hispid; the outermost spreading. Found on rocks near Prague in Bohemia. Schmidt. Root perennial, abrupt. Stems several, six inches high, erect, beset from top to bottom with axillary, distant, very hispid flower-stalks. The flowers are small, like *Crepis tetrorum*. Willd.

8. *P. hispid*. Hispid Ox-tongue. Ait. n. 3.—Leaves oblong-lanceolate, nearly entire, sessile, hispid, as well as the calyx, with hairs barbed at the point.—Native of the Levant. A specimen in the Banksian herbarium, it is said, shews this plant to have been cultivated before 1789, in the gardens of England. It is marked as a hardy perennial, flowering in July and August. We have had no opportunity of examining this species, but we greatly suspect it to be no other than our *pauciflora*, whose pubescence answers to the description, and which we believe was communicated to Sir J. Banks, as well as to Kew garden, in 1788 or 1789.

PICRIUM, from *πικρὸς*, bitter, an appellation for which Schreber has exchanged the barbarous *Coutoubea* of Aublet. Schreb. Gen. 791. Mart. Mill. Dict. v. 3. See EXACUM.

PICROTOXINE, in *Natural History*, a name given by M. Bouley to a peculiar substance, which he extracted from the "Cocculus indicus," and to which that substance owes its deleterious qualities. It may be obtained by the following process. Boil the seeds deprived of their pericarp in a sufficient quantity of water; filter the decoction, and precipitate it by acetate of lead; then filter again, and evaporate slowly to the consistence of an extract; dissolve this extract in alcohol, and evaporate the solution to dryness. Repeat these solutions in alcohol and evaporation, till the residue is wholly soluble in alcohol and water. It then consists of picrotoxine mixed with a little colouring matter; agitate it with a very small quantity of water, the colouring matter is dissolved, and the picrotoxine separates in small crystals. Its properties are as follow: its colour is white, and it crystallizes in four-sided prisms; its taste is disgustingly bitter; 100 parts of boiling water dissolve four parts of picrotoxine, one-half of which separates as the solution cools; the solution does not alter the colour of vegetable blues; alcohol, of the specific gravity 0.810, dissolves the third of its weight of this substance; a little water throws down the picrotoxine, and the addition of a greater quantity redissolves the precipitate; sulphuric ether, of the specific gravity 0.700, dissolves only 0.4 of picrotoxine; it is insoluble in oil, both fixed and volatile; diluted sulphuric acid does not act upon it; concentrated acid dissolves it, assuming a yellow colour; when heat is applied, the picrotoxine is changed and destroyed; nitric acid dissolves it without the disengagement of nitrous gas; the solution is yellowish-green; when heat is applied, the picrotoxine is converted into oxalic acid; but about eighteen parts of nitric acid are requisite to produce this effect:—muriatic, oxymuriatic, and sulphureous acids, do not act upon it:—acetic acid readily dissolves it:—carbonate of potash precipitates it from this solution unaltered:—potash, soda, and ammonia, diluted with ten times their weight of water, readily dissolve picrotoxine:—when triturated with potash, it assumes a yellow colour, but does not emit the odour of ammonia:—

when heated, it burns without melting, or flame, exhaling a white smoke, which has a resinous odour:—when distilled, it yields very little water, and gaseous products, but much yellow-coloured empyreumatic oil, and a brilliant bulky charcoal remains behind. *Annal. de Chim.* vol. 80.

PICTA TOGA. See TOGA.

PICTAVIENSIS, or PICTONUM *Colica*, the *colic* of *Poitou*, called also the *painter's colic*, *Devonshire colic*, and, in the West Indies, the *dry belly-ache*, is now known to be occasioned solely by the poison of lead, and is more properly called the *saturnine colic*. See COLICA.

PICTOU, in *Geography*, a growing settlement of Nova Scotia, in the county of Halifax, built on the bay of Pictou, on the N.E. coast of the province, nearly opposite to the S.E. end of the island of St. John's, and about 100 miles distant from Halifax, with which it has a free and speedy communication. It contains 40 houses, and 500 inhabitants, mostly Scots. Formerly it was inconsiderable, but now is the most flourishing place in the province. Its trade consists chiefly in the exportation of timber, annually shipped to Great Britain and Ireland, in return for which are imported dry goods.

PICTS, in *History*, a denomination given to the inhabitants of the eastern parts of Scotland, concerning whose origin, the etymology of their name, and various particulars relating to them, antiquarians, after all their researches, have been divided almost to the present day; though we have reason to believe, that the principal questions in dispute with regard to these people are now nearly settled. The first mention of them under this denomination occurs in a panegyric of Eumenius, the orator, during the year 297, and again in 308; who, referring to Constance's arrival in Britain in 306, for the purpose of repelling the Caledonians and "other Picts" (*Caledones aliique Picti*), expressly and significantly represents them as the same people. The Caledonians had been often mentioned before by classic authors, under other names; but on this occasion they were called Picts, on account of their peculiar seclusion from the Roman provincials on the south; and they were often mentioned, during the decline of the Roman empire, by orators, historians, and poets, under that significant appellation. As the learned professor of Autun knew the meaning of his own language, says Mr. Chalmers, we are bound to regard the Caledonians and Picts as the same people, at the end of the third century. Towards the conclusion of the fourth century, Ammianus Marcellinus (l. xxvii. c. 7.) spoke of these people in the same manner. The poets also, referring to the custom of painting themselves, that prevailed among the Caledonians, and perhaps erroneously imagining that they were on this account called *Picti*, confirm the same opinion. Thus Claudian, about the year 400, "De Bello Getico," alludes to them in the following lines:

"—— ferroque notatos
Perlegit exanimos Pictō moriente figuras."

And in his panegyric on Theodosius's victories, he again thus speaks of the Picts:

"Ille leves Mauros, nec falso nomine Pictos
Edomuit."

It appears, therefore, from the mention of classic authors, during three centuries, that the Picts were Caledonians. That the Caledonians were the North Britons, who fought Agricola, at the foot of the Grampian, we know from the nature of the events, and the attestation of Tacitus; and that the Northern Britons of the first century were the descendants of the Celtic aborigenes, who were the same

people as the Southern Britons, during the earliest times, has been satisfactorily proved, says Chalmers, as a moral certainty.

At the period of the Roman abdication, A.D. 446, when the Pictish period commenced, the sixteen tribes of Picts, under this appropriate denomination, ranged unsubdued beyond the wall of Antonine, and acquired from their independence higher importance, when they were no longer overawed by the Roman power. By degrees they became the ruling nation, and retained their dominion throughout four centuries of the North British annals, *viz.* until A.D. 843, when the Pictish period terminated. It has been a subject of dispute, as we have already intimated, whether the Picts were of a Celtic, or of a Gothic origin; but it has been shewn, on the most satisfactory evidence, that their genealogy may be clearly traced through three successive changes; from the Gauls to the Britons; from the Britons to the Caledonians; and from the Caledonians to the Picts; thus changing their names, but not their nature. The venerable Bede, who was contemporary with the Pictish government, speaks doubtfully of the Picts, as the second people, who came into this island from Scythia; first to Ireland and thence to North Britain, and many later writers have been misled by his authority; but it has been since concluded, from more accurate examination, that the Picts were undoubtedly Caledonians, that the Caledonians were Britons, and that the Britons were Gauls, or Celts. Towards the conclusion of the third century, the Caledonians acquired the comprehensive appellation of Picts; and this appellation, before the end of the fourth century, superseded every other name. Some writers, indeed, maintained, with Buchanan, that a great part of North Britain was, even before the invasion of Britain by the Romans, inhabited by a people called Picts, Piks, or Pechts, who are thought by some to have migrated from Scandinavia, and to have driven out the ancient inhabitants; nevertheless it is said, that they were a Celtic colony, and spoke at least a dialect of the language of the original inhabitants. But for these assumptions there seems to those who have been industrious in their researches no sufficient authority. Camden, whose testimony commands deference and respect, is the first person of eminence who avowed it as his opinion, that the Picts were the genuine descendants of the ancient Britons; and Selden, having duly considered the subject of the origin of the Picts, advises the reader, rather to adhere to the learned Camden, who makes the Picts very genuine Britons, distinguished only by an accidental name. Different etymologies have been given of the name *Picti*. The most probable opinion is, that these distinguished descendants of the Caledonians acquired this name, during the Roman period, from their relative situation, and local qualities, as compared with the romanized Britons, who lived in the province of Valentia, within the Roman wall; whereas the Picts dwelt without the province, and roamed free from the Roman authority, and separated from the romanized tribes within, who often felt their rigorous incursions, and frequently required the protection of the Roman government. In the British speech, the Picts were from these distinctive qualities called "Peithi," which was naturally latinized by Roman writers into "Picti," when, during the third century, they came to be the objects of Roman observation, by assimilating the British term to their own familiar word "Picti," which was descriptive of the custom of painting the body, seen by the Romans among the Northern Britons. "Peithi" in the British language signifies "those that are out or exposed," "the people of the open country," or of the waste and desert; and also those "who scout, or lay waste." Accordingly the "Peithi" and "Peith-wyr" are the terms commonly

commonly used by the Welsh poets for the Pictish people; and on the confines of Wales, those Britons who threw off their allegiance to their native princes, and set up a *regulus* of their own, or adhered to the Saxons, were called "Peithi" or "Picti." Moreover, the Welsh, in order to distinguish the northern from the southern Picts, called the Caledonian Picts by the appellation of "Gwyddyl Pichli," or "Fichli;" the *p* of the British being often changed into *f*. We may here add, that the Welsh, as Owen observes, in his Dictionary, apply the term "Brython," and Brythonig, to the Picts, and hence it has been inferred, that the Welsh considered them as Britons.

Innes, in his "Critical Essay," has given from an ancient chronicle a series of the Pictish kings, comprehending forty, who succeeded one another from Druif, the son of Erp, A.D. 451, to Bred, A.D. 843. These Pictish kings successively governed uncivilized clans, during the rudest ages. In the third century, they were in a high degree barbarous; but in process of time they gained some improvement from their intercourse, either civil or hostile, with the romanized Britons, or Roman armies, and still more from the introduction of Christianity among them.

The appropriate country of the Picts acquired different names, in successive periods. The mountainous part of it was denominated by the first colonists in their native speech "Alban," *i. e.* the superior height. This appellation, originally applied to the hilly region that forms the west of Perth, and the north-west of Argyle, was in subsequent times extended to the whole country. In the first century, the British term "Celyddon," literally signifying the "Coverts," was applied by the Roman authors to the whole country on the N. of the Friths, though the same name was restricted by the Roman geographers to the interior highlands, lying northward of Alban: and both these appellations were afterwards applied more largely to North Britain. The Pictish chronicle, from the Pictish people, called their country "Pictavia." The annals of Ulster generally mention this country under the name of "Fortruin," derived, with a slight variation, from "Fother," the name of the Pictish capital. Saxo, the Danish historian, plainly refers to "Petia," as the name of Pictland; and this "Petia" of Saxo approaches the nearest to the British term "Peith," or "Peithw," which the British people applied to the open country, lying along the east coast, on the northward of the Forth. In the sequel of this article, we shall merely mention some incidental circumstances that occur in the history of the Picts. The reign of Bridei was rendered illustrious by his conversion to Christianity, under the instruction of Columba, in 565. From this epoch, the Picts may be considered as Christians, though this change in the profession seems not to have produced any considerable alteration in their principles, or their customs. About the year 724, a civil war commenced among the Picts, and they were at the same time exposed to the destructive incursions of their enterprising neighbours, on the north-east. The anarchical governments of Norway, Sweden, and Denmark, during the middle ages, produced the pirate kings of the northern seas, and these were for a long time the scourges of the navigators, who sailed from every nation, on the European seas. In 839 the Vikings, as they were called, landed among the Picts, and a bloody conflict ensued, which proved fatal to many of the Pictish chiefs. Weakened by domestic strife, and by a formidable invasion, the Picts were unable to resist the arms, or to defeat the policy of Kenneth, the son of Alpin, when he acquired their distracted government, A.D. 843.

With regard to the *language* of the Picts, it has been

observed, that as they were merely the Cambro-Britons, who appeared at various periods under a new and lasting name, the speech of the Britons and of the Picts must have been the same. Accordingly Aber-nethy, the metropolis of the Pictish kingdom, derived from the British language its appropriate appellation, which it retained till the latest period of the Pictish government; and upon investigation, which we have not room to pursue, it has been found that the most ancient repertory of Pictish language is the topography of North Britain. The Pictish language may also be traced in the vernacular language of North Britain even at this day: and the municipal law of that country has even borrowed several of its significant terms from the Pictish speech. This language of the Britons and Picts has been considered, by judicious writers, as masculine, copious, and poetical. Although from not seeing it, in its primitive orthography, it seems to be harsh, in its sounds, to the ears of strangers, yet, when it is put into verse, and is read with its genuine pronunciation, it is, like the Greek and the Hebrew, melodious and strong. As the Celts were the original settlers of Western Europe, they transmitted to their posterity an energetic passion, for imposing their own significant names on all the prominent objects of nature. In exercising this peculiar prerogative of first discoverers, they displayed those appropriate qualities of their language, which have been remarked; its strength and discrimination, its copiousness of epithet, and its frequency of metaphor. In the subsequent progress of the Gothic tribes over Europe, they adopted the names of mountains, rivers, &c. which had been imposed upon them by the Celts who had previously occupied the countries of which they took possession; and the Saxons, who settled in Britain, were prompted, by their poverty of speech, to follow the example of their Gothic fathers. The Anglo-Saxons, who, in more recent times, acquired settlements in North Britain, borrowed many words from the Celts and Britons, and Scots-Irish, which have maintained their place, and which give strength, copiousness, and ornament to the Scots-Saxon of the present times.

The *religion*, as well as the *language*, of the Picts, derived its origin from those of the Gauls; and hence we may conclude that the Picts and the Britons were the same people, as well as from the identity of their speech, topography, and monuments. The tenets and the forms of the Pictish religion were Druid in the sixth century; as we know from a thousand relics of stone that still engage attention within the district of the Pictish country. The modes of sepulture were the same among the Picts as those of the Caledonians, and the sepulchral rites of the latter were the same as those of the Britons. Their hill forts, their weapons of war, their ornaments, and their modes of life, were the same as those of the Caledonian Britons, of whom the Picts were the immediate descendants. That the Caledonians and Picts were the same people is now universally allowed. Buchanan, Camden, Lloyd, Jones, the M'Pherions, O'Connor, d'Anville, and Stillingfleet, however they may differ in other points, are here all agreed. But some have asserted, without proof, and against probability, that the Caledonians were a Gothic colony, who conquered North Britain in some unknown age. With regard to any Gothic expedition for this purpose, history is silent. Few questions have engaged more general attention among learned antiquaries than that of the origin of the Picts. Mr. Chalmers has given a minute detail of the different opinions that have been maintained with regard to this question; and he concludes with adducing the testimony of the learned antiquary. Mr. Edward King, the author of the "Munimenta Antiqua;"

tiqua;" who maintains, that the Picts were descended from the aboriginal Britons. With him concurs the late Dr. Henry, who says, that we hear nothing of any invasion of the Caledonians by any such distinct people as the Picts; and he therefore concludes, as Innes had done before him, that this denomination was merely a new name, which was given to the old settlers. Upon the whole, Mr. Chalmers observes, the twenty-one British tribes, who occupied North Britain during the first century, remained for ages in their ancient settlements. Five of those tribes were subdued by the Roman arms, and civilized by the Roman arts. After the Roman abdication, these five tribes continued, in their appropriate country, on the south of the Friths, distinguished by no other circumstance than their civilization from the sixteen tribes, who equally remained unsubdued on the north of the same Friths, and who obtained the name of Picts. These were as much the descendants of the Cambro-Britons as their southern neighbours of Strathclyde, who were noticed, till recent times, as genuine Welsh.

Upon the death of Bred, the last Pictish king, A.D. 843, Kenneth, the son of Alpin, king of the Scots, obtained the Pictish government; in his person a new dynasty commenced: the king was changed, but the government remained the same. The Picts and Scots, who were a congenial people, from a common origin, and spoke cognate tongues, the British and the Gaelic, readily coalesced; and the union of the Picts with the Scots, A.D. 843, conjoined the separate dominions of both, and led on to the annexation of other territories. The Picts had been confined, for ages before that epoch, by the Forth on the south, and Drumalban on the west, and by the German ocean on the east and north. Their southern limits had been fixed at an early period by the prevalence of the Roman power. They were induced, probably by the long continuance of that power, to consolidate the distant districts of the various tribes, which had, from the earliest times, divided their country, by their spirit of independence, and enfeebled their strength, by their desires of revenge. Tradition reported, even so lately as the twelfth century, that Pictavia had been once separated into six kingdoms. But these fictitious monarchies had long ceased to exist before the memorable union of the Picts and Scots, except in the natural divisions of the country, as they had been named by a Celtic people. The Scots, at that epoch, possessed the whole western coast, from the Clyde to Loch-Toridon, with the adjacent isles. In the days of Bede, their colonies extended from the northern margin of the Clyde, along the shores of the Irish sea, far into the north: and in the course of another century, they occupied the ample extent of Argyle, from the river Clyde on the south to Loch-Ew and Loch-Maree on the north, and from the sea on the west to Drumalban on the east. Such were the dominions which the Scots brought with them, when, by overpowering the Picts, an union was effected between them, both of authority and of territories. Chalmers's Caledonia, vol. i. See SCOTLAND.

Picts' Wall, in *Antiquity*, a famed piece of Roman work, begun by the emperor Adrian, A.D. 124, on the northern bounds of England, to prevent the incursions of the Picts and Scots.

At first it was made only of turf, strengthened with palisadoes, till the emperor Severus, coming in person into Britain, repaired it, as some say, with solid stone, reaching eighty miles in length, from the Irish to the German sea, through Carlisle and Newcastle; with watch-towers garrisoned, now called castle-steeds, at the distance of a mile from each other.

It does not appear, with sufficient evidence, that Severus's

wall was formed of stone: Bede expressly asserts the contrary, though Spartian intimates that Severus built both a *murus*, i. e. a wall of stone, and a *vallum*, or a wall of turf. Bede's words are these: Severus, after several great and difficult engagements, thought it necessary to separate that part of the island which he had recovered, from the other nations that were unconquered; not with a *murus*, as some think, but with a *vallum*: now a *murus*, says he, is of stone; but a *vallum*, such as they made round a camp, to secure it against the attacks of the enemy, is made of turf, cut regularly out of the ground, and built high above ground like a wall, with the ditch before it, out of which the turf has been dug; and strong stakes of wood all along the brink. Severus, therefore, drew a great ditch, and built a strong earthen wall, fortified with several turrets from sea to sea. The learned Camden adopts this opinion; and adds, that Severus's wall is expressed by no other word than *vallum*, either in Antoninus or the Notitia. *Camd. Brit. vol. ii. p. 1045.* See AGGER.

This wall was ruined several times by the Picts, and often repaired by the Romans. At last Ætius, a Roman general, ordered it to be rebuilt of stone, about the year 420; but the Picts ruining it in the year following, it was no longer regarded but as a boundary between the two nations. The wall was eight feet thick, and twelve high from the ground: it ran on the north side of the rivers Tyne and Irthing, up and down several hills: the tract, or remains of it, are to be seen to this day in many places, both in Cumberland and Northumberland.

The inhabitants of the country pretend, that there was a brazen trumpet or pipe, so artificially laid in the wall between each castle and tower, that upon the apprehension of danger at any one place, by the sounding of it, notice might be given to the next, and then to the third, &c. whence it derived the ancient name *cornage*; and in the inside a fort of fortified little town, now called Chester, the foundations of which appear, in some places, in a square form.

PICTURE, an imitation or representation by lines and colours of any natural object. Such representations are also called paintings, from the name of the art by which they are produced; which being capable of general application, and of great influence upon the mind, has, at all times, since men have cultivated their intellectual powers, been regarded with peculiar interest.

Were that art employed merely as ornamental, as the amusement of leisure time, or an agreeable source of innocent delight, we could not regard it as unworthy of attention; but when considered as an useful instrument of instruction, an universally intelligible means of communicating ideas, with all the force, the brilliancy, and sublimity of poetry, and with some advantages superior to those possessed by that divine art, it claims undoubted respect.

The well-known aphorism of Hippocrates, that "art is long, and life is short," applies to no peculiar art so well as to painting; since not only has no single man unaided been able to carry it to perfection, but in the progressive accumulation of knowledge through the lapse of ages, succeeding ones benefiting by the experience and examples of the former, no man has yet arrived at that degree of excellence in the practice of it, which a perfect union of all its principles and qualities would produce.

The power of exercising this useful and delightful art has, at all times, been slow of acquirement, as the history we have given of its progress under the article PAINTING evidently shews. It has this diversity in its growth from that of poetry; which has shone with conspicuous lustre at very early periods of human culture, whilst painting has never flourished,

PICTURE.

flourished, but in gradual advance with the general improvement of mankind; and has been truly conspicuous only at those times, when the arts of civilization have risen to their highest pitch of excellence in the countries where it has been practised.

In no art has the professor greater or more numerous difficulties to encounter than in painting: since he not only is under a necessity, equally imposing as is the historian or the poet, of obtaining accurate ideas of the events he records, or the scenes he displays; but he has also to invent and perfect himself in the medium, or language, in which he communicates his ideas, before he proceeds to the use of it. This medium is utterly out of the ordinary way of human culture; and whatever may be the aids derived from the advantages we now possess, in having the experience of our predecessors as our guide, there must have been infinite difficulty in bringing it so near to perfection as the great masters have done; and it has been only effected by an extremely gradual progress, and the union of successive exertions operating in one continued line of action. Even now, with the works of preceding painters in our hands, the language of the art (the value and use of its materials) is necessarily, in a very great degree, new to every professor who attains any tolerable degree of eminence. And though it must, no doubt, appear very extraordinary to those who have never made the practice of painting their study, that when such exemplars of art remain to us, men possessed of good sense should hesitate in producing the like; or that, when they are become capable of making copies, perfect almost to deception, they should not be also capable of employing the means they have acquired, in a systematic mode, in works of original invention; yet the reverse, in many instances, is a fact of universal notoriety; and proves incontrovertibly, that the art of painting, particularly when employed upon original matter, is more dependent upon mental exertion, than manual dexterity, in its execution, as well as in its object and effect; and well worthy of the rank assigned it by the Greeks among those arts which they denominated liberal.

Notwithstanding the high degree of perfection to which this art has been carried, no scientific or complete systematic arrangement has yet been adopted for the perfect guidance of the painter; nor does it appear probable that any one ever can be formed, that will effectually apply to the practice of an art such as his, which is capable of such an infinite diversity of character and effect. A man of enlarged mind, carefully consulting the pictures of preceding artists, cannot avoid acquiring information which may assist him in his labour; and it is by this means, more than by regular systematic instruction, that painting has arrived at eminence. But then, the power of extracting valuable information, and of employing it judiciously, even in the practical part of the art, is almost as rare as the superior ones of invention, of composition, or design. Thus, however, as in other arts or sciences, something is ready done to the hands of the painter; he builds upon a foundation laid by his predecessors; but the benefit is derived principally from seeing what may be done, rather than in being informed how to do it. He has yet to discover what colours or materials will most effectively combine to attain his end, even in copying pictures; and when he ventures to attempt the imitation of nature, to trace her varieties and intricacies through the numberless paths of light and shade, and colour, and in all the diversities of view in which objects present themselves, then the whole value of the information obtained by the study of the works of former masters in the practical part of the art, falls still lower in

the scale of utility, from the extreme difficulty of applying it. Perhaps there cannot be a greater proof of the originality of thought required in the mere practice of the art, than the great diversity of the works produced in competition with old pictures, by those who have at different periods admired and studied them enthusiastically. No man of genius, or of good sense, will, however, slight the advantages which the study of them may afford him. He may not, at first, obtain the full and actual information he seeks, but the attempt will lead him in a right way to the discovery of the true principles of art; and time may be saved for their application, which, without such helps, must have been lost in experiment. Without tuition, the only mode of advancement in mental culture is by discovering our imperfections; a mode by no means favourable to rapid improvement, when there is nothing better than our own productions to operate as a corrective. But when good examples are before us, and our first object is to rival them; this advantage, at least, is derived from the attempt, that we set forth in a road which leads to a happy termination, and have no occasion to retrace our steps; like him who starting without a guide, wanders in the mazes of ignorance.

If to acquire possession of the means of the art of painting, the mere power of combining colours in such a manner as to produce imitations, be thus encompassed with difficulties, how great is the task of him who undertakes to unite its higher principles with its noblest aims; and successfully to apply it in extended compositions, illustrative of history, of poetry, or of philosophy. Such has been the exalted and successful ambition of many painters: and their works have proved the beauty, the utility, and sublime power of the art they professed, when exercised by genius, and applied with energy.

To effect this, the hand and the head must equally combine in their efforts. No vulgar or uninformed man, no one who has not taken pains to cultivate and improve his mental faculties, can be a great painter, in the exalted sense in which we view it. Whatever is requisite for the poet or the historian, in cultivation and information, ought not to be disregarded by the painter, whose desire is to exercise his art in an honourable or useful manner, as the great masters among the ancient Greeks and in the more modern Italian schools have done. If it be not required of him to become as learned in natural philosophy as Newton, he ought not to be unacquainted with its principles: his business is not merely with the surface of things, if he wishes to represent their appearances in a sensible and characteristic manner. A knowledge in the sciences, sufficient to inform him of the principles which direct and govern the actions of animals, and cause the various appearances of natural unanimated objects, cannot, or ought not to be uninteresting to him whose whole life is employed in contemplating and representing their forms or their effects. If he knows the natural structure of an animal, its modes and habits of life and action, he at once, and without hesitation, directs his attention to the parts most materially necessary to its delineation; and does not lose his time, as an ignorant person would do, in representing those parts, which, though they may, from accidental causes, strike the eye, yet are, in effect, prejudicial to true character; and if marked too strongly, even with the hand of ability, counteract the effect of those more efficient in general representation, which always ought to be the sole object of him who wishes to be a great painter. In the representation of objects of unanimated nature, a just comprehension of their causes and effects will, in great measure, operate in the

fame

PICTURE.

same way. We do not mean to say, that if a man happens, for example, to know the cause of a rainbow, or can form a pleasing theory upon it, that he will therefore be able to select and blend, in a proper manner, the colouring substances necessary to paint one with truth and taste: we have already said that this is a matter utterly unconnected with all other species of information: but, if he add to his technical and practical acquirements the scientific one alluded to, he will most undoubtedly set about the task with less confusion of mind than the most ingenious among those who are ignorant of it; and will the more easily satisfy himself of the tones to be employed; and, of course, be more fully assured of its propriety when done, and know when to leave his labour with greater certainty of success.

To this knowledge of the principles of nature, an unremitting attention to her productions is absolutely required of the painter. To him whose mind is devoted to the art, no scene can be vacant or uninteresting; every place affords him matter of observation and investigation. All appearances of natural objects, from the simplest to the most awful; all the actions of man, the varied expressions of his countenance, when under the influence of his passions; the characters of health, of age, of beauty, and even deformity, are entitled to his regard, indeed demand his closest enquiry into their most characteristic lines and effects. All the varieties of country, the characteristic forms of animals, trees, rocks, &c. &c. ought necessarily to be known to him; in fact, there is no object the observation of which may not, either immediately or collaterally, be useful to him. The trouble which attends this constant application of the mind, is in the end most highly rewarded. His sphere of vision is enlarged, almost to the creation of another sense, unknown to those who are uninitiated in the art, which finds continual nourishment in scenes even of apparent dulness and insipidity: imagination is strengthened by it, as the power of creating new images increases in proportion to the store of ideas he acquires; and the power of invention or combination, with whatsoever degree nature may have blessed him, is rendered so much the more effective, as he is careful and active in observation; whereas it would be utterly useless, or worse, if not thus supplied by a well digested mass of materials, raised by continual study of nature; particularly of the beautiful, the grand, the interesting, and the characteristic.

This union of general knowledge with practical ability, may be regarded as the material, or the body of the art, the servant of its more exalted and spiritual essence, the power of invention and expression, by which alone the charm of the art is acquired and imparted. In vain may the most skilful operator combine his colours, and arrange his lines; or the most scientific composer determine his groups, and perfect his forms, in exact imitation of nature, if a vivid and correct invention, amply supplied with the stores of nature and of art, has not formed the basis of the work; and if an enthusiastic feeling of expression does not pervade every part, and add, with its glowing energy, the true and forcible impression of life, of motive, and of motion.

To this end, the nature of the subject is the only proper guide; the little that can be taught being quite unavailing, if not directed by feeling and the principle of the subject. Rules are allowed to controul in the arrangement of inferior matters; indeed it is only by science, that scenes of common, or still life, become interesting; but whenever expression, action, character, are required, when the object is, to develop sentiment, to create

emotion, or impress with sublimity, the prime governing power must be the original impression made upon the artist's own mind, and emanating from the subject; to which rules must be made subservient, systematic arrangements must give way, and whatever can be supplied by commonplace tuition, can only be appealed to in a minor degree.

The basis of the art of painting is imitation: its object, when it is best employed, is to excite emotion. The pleasure or pain which it is capable of exciting, rests not, however, altogether upon actual imitation; since all the moral purposes of the art may be effectually answered by lines only; at least, all that can be imparted by the action and expression of figures. (See *OUTLINE*.) It is sufficient for those purposes, that a hint intelligible to the understanding be given, by which the mind is filled with idea sufficient to fix its attention. Hence arises the notion, which has been supported and opposed with considerable power by men of talents, that an union of the qualities of the different schools of painting would be injurious, instead of beneficial, to the practice and effect of the higher object of art. (See *PAINTING*.) It is a certain fact, and allowed by both, that too close an imitation weakens the sentiment of a picture; abstracts the mind too much from the object to fix it upon the means; and by dividing the interest, diminishes its power. We do not mean by too close an imitation, that narrow view of nature, which, without selection, takes men and things as they are, and copies defects and beauties with equal fidelity; but would extend it to the most perfect system of combination and selection, unless wrought upon the general principles of ideal nature. (See *IDEAL*.) Yet it is not in the quality of the imitation the danger lies, so much as in the degree; and we perfectly agree with those who are in favour of truth in colour and effect, as well as form: and know no reason why the imperfect colouring of the Florentine, or any other school, should be an allowed medium, through which, by incorrectness, the mind should be made to conceive of what is right; in preference to another, which, without disturbing the imagination by presenting images too minutely just, yet has its basis in correct imitation.

Nothing can justify the impropriety of attempting to make falsehood the source of truth. It has by no one ever yet been made apparent, that an hieroglyphic is more emphatic than a true image; and till that is done, we must be excused from believing that a false imitation of nature can be substituted, with equal effect, in place of a just one. Whatever is introduced must, of course, be subject to the governing principles of the art in chiaro-scuro and tone of colour; and also in the degree of imitation, or of advance towards the appearance of absolute projection and reality; and these all depend entirely upon the nature of the subject. But what is done, ought surely to be founded upon the general principles of nature, and not upon a fictitious substitute, which perhaps may have originated less in choice than necessity. The limited number and kind of the colours employed in fresco, together with its peculiarities of execution, forbade, for a while, any great degree of richness, of brilliancy, or of truth, in colouring, but we have many specimens to prove, that when more beautiful, more artful, and true colouring was effected by the use of oil, that the great masters themselves of the Florentine and Roman schools attempted, as far as possible, to impart something of it to their frescoes. Raphael's pictures of the Heliodorus and the Miracle at Bolsenna, are very striking examples of this fact, that true, though general imitation, was the guide of his pencil; and still more did he exhibit his sense of its value in his picture of the Transfiguration; and

PICTURE.

in almost all his productions in that medium which permitted the attempt freely. Even M. Angelo sought to unite the richness, vivacity, and reality of Titian's colouring, with his own grandeur and simplicity of design, by employing the pencil of Sebastian del Piombo, and others, upon his own compositions.

We cannot conceive that the great style of design may not have its appropriate tones of colour true to nature, yet suitable to its dignity and simplicity in form; and probably Sir Joshua Reynolds and Mr. Opie, who stand opposed to each other in opinion in this matter, may not, in reality, so widely differ, as at first sight they appear to do. The former asserts in his fourth discourse, that "there are two styles of historical painting, the grand style," (that of the Florentine school,) "and the splendid or ornamental," (that of the Venetian); and again, "that the great style stands alone, and does not require, perhaps does not well admit, any addition from inferior beauties." Had he not in a former part of the same lecture asserted, "that the pictures of the Venetian school were not only too brilliant, but also too *harmonious*, to produce that solidity, steadiness, and simplicity of effect, which heroic subjects require," and which simple and grave colours only can give to a work, there would have been no reason to conclude from the other remark, that he thought truth of imitation, with certain limitations, inimical to that grandeur of impression required: and when it is considered, that he is speaking of the characteristic distinctions of the two styles, and has previously declared, that he wished it to be understood, "that in speaking of the Venetian or ornamental style he excluded Titian, who had a sort of senatorial dignity about him, particularly in his portraits," and meant only the works of P. Veronese and Tintoretto; and that, in another place, he declares it to be his opinion, that "the tone and style of colour of Ludovico Carracci is the proper vehicle for historic art," we cannot believe that his mind could be made up to the approval of the dry, hard, and imperfect management of colours exhibited in the general style of the large fresco pictures of the Florentine and Roman schools, when compared with the truly fine efforts of imitation by Titian, or even some of those works themselves more perfect in harmony, depth, brilliancy, and truth. It appears most probable that his ideas of dissonancy, were principally attached to those peculiarities which distinguish the styles; where they turned aside from nature, to mark more strongly their peculiar objects; and which separate completely and necessarily the severity and purity required by the one, from the luxuriance and sensuality attached to the other.

To this opinion Mr. Opie assents, when he cautions the painter to "beware of losing the terrors of the crucifixion, in the magnificence of a triumphal show; or of disturbing the pathetic solemnity of the last supper, with the impertinent gaiety of a bacchanalian revel;" and justly observes, that "the grand style consists not in neglecting to give all the apparent truth, force, and reality of objects to the eye; but in supplying the defects, and avoiding the redundancies, of individual and imperfect forms;" and adds, that "colouring is not less capable, by rejecting what is merely accidental, and copying only the general and characteristic hue of each object, of being elevated to the same ideal standard."—"One simple and refined principle operating equally on all parts of the art," must surely produce a correspondent effect in all: and there is no apparent reason, why the same system of operation, which, whilst it elevates, still maintains design in purity, should not produce in colouring a correspondent degree of expression, of simplicity,

Vol. XXVII.

and of truth; without violating harmony, or presenting discordant and harsh contrasts in shades and colours.

We must again repeat, however, that the *degree* of imitation is the essential part for consideration, as being that wherein the difficulty lies. If colours are to be reduced in their tones, and made serious in their effect, to suit the dignity of historic design, they may be reduced as twilight reduces them, in which forms and colours together are seen only in general masses. The St. Peter Martyr by Titian, is a fine exemplar of that kind of effect; grand and imposing, yet true. Time has indeed produced some changes in the effect of that work, but the principle of imitation remains discernible to a well-informed eye, and is broad, yet just; simple, yet effective and rich. The execution of the inferior parts is not, as has been said by a learned critic, (see *Edin. Rev.* Aug. 1810, art. Barry,) wrought "with all the accurate truth of a botanist;" and if they were so executed, it would, as Sir J. Reynolds has more justly said, only be labour wasted. They have truth in character, but not minute botanical markings; and it perhaps would puzzle a botanist to do more than point out the genus of the plants upon the fore-ground. Nature, however, is evidently the guide, and Titian has only omitted those parts which, if he had imitated them, would never have been seen at a proper distance for viewing the picture, and which being unnecessary, must have diminished the general interest if made observable. They are not even seen in nature minutely, when the eye is not immediately directed to them, but is attached to some peculiar object which they surround; and the imitation of them therefore ought to be general, as the natural impression is; if it is wished that the principal object should remain undisturbed in effect.

But however interesting and agreeable, perfect and full imitation in colour, and light and shade may be, yet wherever it is intended to produce a great or sublime effect, it must be remembered that form is the most effective agent which painting can employ. Sir Joshua Reynolds, fully conscious of its value, has said that "he who is capable of delineating fine forms, even if he can do nothing more, is a great artist;" and in perfect consonance with this opinion, the principal object of all the greatest masters has been to acquire a knowledge of the forms of natural objects, and the power of delineating them. Annibal Caracci is said to have told his scholars, "first to make a good outline, and then, however the middle be filled up, it must be a good picture." This, however, must be regarded as a freedom of speech, too loose to be followed to the letter; yet it conveys his strong sense of the powerful necessity of employing skilful design,—the original foundation and the most useful principle of the art; without which, the others are completely nugatory.

This simple principle, which apparently offers little difficulty to be overcome, requires, nevertheless, the deepest study, and the most constant practice, in order to obtain its two most important requisites,—correctness and expression. The only mode of acquiring these, is derived from that general study of nature which we have spoken of above. No man, for instance, can draw the human figure in such a mode, as to correspond with either of those terms, who is not well versed in the anatomy of it; not even when it is in a tranquil state: how much less so then, when it is animated and in motion; when the agitations of the passions extend, or contract the limbs; or the gentle sentiments of affection cause them to play in graceful undulation. Without the knowledge of the structure of the bones, the forms and attachments of the muscles, and their consequent varieties of ac-

PICTURE.

tion, he must necessarily confound the essential with the useless; the solid, unchanging, and characteristic forms, with the integuments that encumber them and disguise their action.

It is not, however, in outline alone, that the understanding of form is requisite to the painter; since in a style correspondent to the character which that possessor, should the space it circumscribes be wrought by the *chiaro-scuro*, which comes next in value among the principles of the art, and by which the form suggested to the fancy by outline is rounded, made to project from the ground, or from other forms, to obtrude itself upon the notice of the spectator, or recede and fall back from the view. (See *CLAIR-OBSCURE*.) The passion or the action which the drawing of the outline presented, may be in most cases greatly assisted by this branch of the science of art; as in poetical scenery, for instance, and whatever depends upon illumination in tone or degree. Scenes of horror and obscurity, which participate of the mysterious or sublime; and the enchanting bland effects of serenity and repose, alike find in *chiaro-scuro* their main ornament and support; though colouring, when judiciously applied and conducted, is that which lends the finished perfection of the art, and completes the degree of illusion which is its aim. See *COLOURING*.

The best mode of acquiring the practical part of painting, is certainly, in the first instance, to copy the works of good painters, under the guidance of an able instructor. Slight, however, in comparison with the object, is all that tuition can afford in this matter. The arrangement of the palette, the preparation of colours, the general principles of their union or opposition, and consequently the order of their most agreeable arrangements and most powerful effects, together with the best or readiest mode of exercising the implements of the art, may of course be communicated and learnt. The mind may be directed to seek for refinement in taste of form and colour, and to select and combine them; but will be taught in vain, unless nature has implanted the seeds of discrimination, of judgment, and of taste itself. And even if somewhat of this should be imbibed, vain is every effort to impart imagination, invention, or the feeling of expression: these are qualities, improvable, when possessed, by exercise and study; but not to be created by the power of man. To those who possessing them, feel the inclination to study the art of painting, we would say,—the true mode of learning to rival the successful efforts of the great masters, is not by copying servilely the surfaces of their works; but when the power of execution is in part obtained, endeavour, while copying, to search into the principles by which compositions are arranged, and upon which their execution is effected: wherein consist, and what are the peculiar features of colour, or of handling, that give the character of grace and taste expressed in them; and what peculiar traits of imagination most beautifully and most justly develop their subjects. In investigating pictures with views dictated by such desires, it will frequently be found, that what appears to superficial observers mere freaks of fancy, or mere recreation or indulgence of the pencil, is the result of the most deeply inventive faculty, and admitted, not for pleasure only, but for the most important purposes. Such, to instance in a work open every season to the inspection of artists by the liberality of the marquis of Stafford, is the little vase in the middle of Titian's picture of the bath of Diana. To the common observer it presents, as intended, a proper accompaniment to the toilette of the goddess, perhaps a vessel containing perfume, no matter whether disposed of here or there, provided it were introduced; yet more an ornament than a necessary

adjunct in the composition: in the eyes of the artist, it is beheld as an instrument of inestimable value, in preserving the brilliancy and richness of flesh in full, yet just character, by its own superior power of reflection; and producing a brilliant focus to the light of the picture, without attracting the eye too powerfully to itself; not to speak of its interrupting, by its beautiful form, the too great regularity of the mass of stone-work on which it stands. It should never be forgot, that painting is more a work of the mind, than of the hand; it is the former which creates, the latter only displays; and though the art consists, absolutely speaking, in that display, its value is nothing, if not supplied with well selected, well arranged materials; and is comparatively of easy acquirement, as is testified by every day's experience. We must not be thought to undervalue the benefit of copying. It seems almost absolutely necessary, under judicious management, to perfect the hand, and shorten the labour necessary for acquiring the practical part of the art, and therefore the more early in life it is begun the better; and if, while the hand is engaged in the labour of it, the mind be employed in developing the principles upon which the work is conducted, then there is the chance of advantage being derived from the facility of devoting so much time to one object; as it affords the opportunity of deeper and more solid investigation. One thing is certain, that there is no mode of obtaining excellence in painting but by a regular and steady pursuit. Let the original foundation of genius and talent be as good as it may, nothing short of persevering industry can raise the superstructure. "There is no royal road to the arts," no short cut whereby the painter may arrive at the end of his course, and escape the labours of study and exercise; and of this the practice and declarations of the very greatest artists are satisfactory proofs. Apelles, it is said, never allowed a day to pass without exercising his art in a greater or less degree. The industrious exertions of the most able of the Italian artists are on record: and our own great example, sir Joshua Reynolds, is a host in himself: the immense quantity of his works amply testifying his industry, as well as his attachment to the art. Indeed, without that entire devotedness which supercedes, though it does not exclude, all attention to other objects, it is impossible to obtain that facility of hand, or intelligence of mind, which resorts to the proper sources for a supply of materials to fill the canvas, to improve or embellish a composition, to supply deficiencies or correct defects, by a prompt and happy recollection of the most appropriate objects in form or colour.

The power of execution in painting being secured, the next step is to invent compositions, and execute the parts from nature; combining them with the principles of the art. Then comes the proof, whether the student has felt in his previous studies like an artist, or only as a man possessing no higher qualifications for his profession, than those with which his fellow mortals in general are endowed. Our exhibitions inform us too frequently of the misguided hopes and labours of numerous classes; and gratify us but rarely with any prospect of future excellence or originality; manifesting, by the woeful disappointment and ruin of hundreds, the rarity of the peculiar talent which leads to perfection in painting, and the difficulty of attaining any great degree towards that point, even by those endowed with taste and sense to feel and practise the art with great ingenuity.

It is an advantage to those who are so favoured, if they endeavour to look forward beyond the skill exhibited by others,

PICTURE.

others, and aim at improving even upon the practice of their predecessors. They at least who hold this course are more likely to do something meritorious than others, who fear to launch out of the beaten track: and if their works are conducted upon sound principles, with elevated ideas, and freedom in execution, though they may fail to obtain the object of their wishes; yet they have the best chance of soaring above mediocrity, and the most reasonable ground to hope for applause.

There is, however, a danger attending this ambitious adventure; it is that of mistaking novelty for improvement; of substituting the rashness of a licentious imagination, for the corrected and chaste effusion of true well-founded feeling and judgment. Unfortunately we have too frequent reason to regret, that a man may possess great vigour of fancy, unaccompanied by sound judgment; the want of the latter rendering abortive the vivacity and brilliancy of the former. There are none who are more in need of the corrective hand of a master, than a youth whose imagination outstrips his reason: and it not unfrequently occurs in the practice of the art, that the slow but steady growth of one endowed with a capacity little above the common standard, surpasses in the end the precocity of the former; who, indulging his imagination, plays with the store of knowledge early tuition has supplied, and forgets that the only mode of maintaining the fancy in full force, is by supplying it with new images; which perpetual recurrence to nature only can produce, and perpetual practice only can secure. "Invention," it has been said, "is not creation;" therefore to be a good and ingenious inventor in art, is not to run far into the riot of fancy, by the mere indulgence of it in wanton and monstrous devices; but rather to bring together such combinations of natural objects in their purest forms, as will best illustrate the subject adopted. This is its regulator in the higher class of pictures; in others of a lower order, and particularly what is called ornamental paintings, false and heterogeneous combinations, beginning at first in allegory, and afterwards continued, in spite of their acknowledged absurdity, merely on account of their beauty of form, allow of all the loose indulgence of the fancy which the most vivacious can desire.

When we consider the general extent of the gratification and information afforded by painting, it is extraordinary that a due attention to its principles is not yet admitted as a portion of polite education; since the knowledge of them so evidently increases the pleasure the art is capable of producing: the more particularly when, among the higher classes of mankind, it forms so very constant and material a source of their delights, and is so constantly also a subject of discussion, although arising from, and pretty generally decided by, sensation, rather than reason; and necessarily so indeed! "What can we reason, but from what we know?" Pope has justly said, and how can they decide with reason upon the merits of a work, who are ignorant of the principles upon which it is constructed? Yet so much of it is felt to be desirable, that every gentleman and lady conceives it necessary to learn to draw, regarding the art as worthy of a partial devotion of time: but this is generally effected in so inferior a degree, as to leave the polished learner utterly uninformed of its higher claims, its worthier objects, and its real utility.

To be truly a connoisseur or a judge of the qualities of painting when exercised in its highest style, notwithstanding the impertinent slipperiness of thousands of pretenders, requires a peculiar cultivation of mind; quite as much so as any other art or science requires an initiation into its principles, to be a judge of its effects. Our art,

however, appealing to the sense of sight, more than to reason, and producing its effects from the representation of well known objects, has a great advantage over others, in that its end is more easily comprehended, although the principles which govern its practice are not less abstruse and difficult of application. Most men, therefore, of good mental capacities, are capable of understanding and feeling the grand and general points; such as of colour, whether it be like that of natural objects, under peculiar circumstances; of expression, and if the story be fully and clearly exhibited; and of the general effect of the chiaro-scuro, whether it present an agreeable surface to the eye, &c.; but of the subtleties of arrangement and execution, whereby difficulties arising from the nature and disunion of the materials and parts are overcome; of the delicate hues, which are covertly introduced to produce harmony; and of the art which attaches light to light, and dark to dark, to produce masses, without violating the principles of nature: of these things, hidden as they are in the mystery of the art, none but an artist can well judge; though a portion of that knowledge may be acquired by scientific study without practice. No doubt a man being constantly or frequently in the habit of comparing picture with picture, and both with nature; and reflecting upon the diversities of each, their beauties, and their defects; may acquire a very considerable power of discrimination and judgment in matters of art; and more particularly if he devotes that time, which the regular artist is obliged to employ at his ease, to a careful investigation of nature, and the study of the means and principles of art. A man so tutored may become able to guide, in many points, the pencil of a good painter: still there are many others to which his attention can never be attracted, as they arise only from practice, and consequently can only be known and appreciated by those who are engaged in it. These, it may be remarked, must be of an inferior nature; and true it is they are so, in comparison with the great leading and essential features of a picture, whose subject is of a grand and heroic character; but nevertheless they enter into the aggregate, and assist in affording delight to that organ of sense through which the art appeals to the mind, and more readily enable it to attract attention.

This valuable art has, in the course of the world, been generally regarded as worthy of the greatest honours; and its eminent professors of a proportional share of estimation and rewards. Some of the greatest among men have, at different periods, upheld this opinion of its excellence, as its history testifies (see PAINTING); but Pericles, at the head of the Athenian republic, was the first who duly estimated its value as a national political instrument; and encouraging it, in conjunction with sculpture and architecture, laid, in part, the basis of the long continued fame of the city. He satisfied the people, who murmured at the expence he indulged in in the public works, that by advancing the interests of the arts, he was promoting their own glory. In tracing the mode in which they were employed, we discover the principles upon which they act; and which, being founded upon feelings and sentiments of the human heart, must always produce the same effect.

It is doubtless to the direction in which talent is employed, that we owe its utility, or its power to do mischief. The love of fame was the first object of the Greeks, and their leaders therefore very wisely employed every means to maintain so useful a spirit. In compliance with this, Panæus and Polygnotus were employed by Pericles to adorn the public buildings with paintings, the subjects of which were the heroic actions of the most renowned among their coun-

PICTURE.

trymen; thus perpetuating a record of those deeds which excited to emulation, which, appealing to the natural and instinctive pride of man, in a becoming manner, necessarily leads, wherever it is strongly felt, to great and useful conduct. There is no denying that painting is peculiarly adapted to this species of excitement, its effect being full and instantaneous; as the impression made upon the mind by witnessing the exhibition of a scene of heroism, of distress, or of delight, is greater than any which can arise from a detail of it in description. The interest in the relation is the weaker, as impression succeeds to impression; whereas in the fact, or the representation of it, the whole rushes upon the sight at once. But then it must be acknowledged, that there is this drawback in its effect upon the minds of men in general, that they are not prepared to comprehend more than the general impression; therefore the public works of the Greeks in painting, appear to have been conducted upon the most simple principles, in order that their whole object and intention might be universally embraced.

It is scarcely credible that, in direct opposition to this sentiment of the Greeks, any one should assert, in this enlightened period, that no inculcation of moral or religious truth can be effected by painting; the more so, when the works of Hogarth, the most instructive of painters, are in our hands, and no one who ever thinks of art at all can plead ignorance of them. An assertion that effect has, however, lately been made by a very learned and ingenious author, in a critique on the life and works of J. Barry, esq. (see *Edinb. Review*, August 1810,) and he has gone the length of saying, "that as to conveying moral, religious, or political instruction in pictures, it is the most absurd of all absurd notions." If the ingenious gentleman means, by the word instruction, that kind only which properly belongs to painting, and to which, when speaking of the art, (if he mean well to its cause,) he ought to confine himself, *viz.* that sudden and unavoidable impressions of truth, which most men, not utterly destitute of sense, receive upon the first sight of a well regulated moral, or poetical composition; more particularly such as, being drawn from common nature, applies common objects to its purpose, and presents to the observer familiar incidents, surely every day's experience is against him. We would appeal to himself, if he has never received the impression of disgust at pride; abhorrence of avarice and of sensuality; disdain of vanity and idle waste of time, a prudential hint of the folly of extravagance, and of trusting to gay dissipation for the enjoyment of happiness; from the series of pictures called *The Marriage-a-la-mode* by Hogarth. What moral lectures in rhetoric would, or could, more completely illustrate, in a more universally intelligible manner, the fatal effects of vice, or the beneficial ones attendant upon virtue, than that ingenious painter has done in this, and others of his productions; as the industrious and idle apprentices, the Rake's and the Harlot's progress, &c. &c.; and yet with these designs in his hand, has he risked so unjust and ungenerous a sentiment as his assertion conveys. Ungenerous, because, if true, it can be productive of no good to extend such an opinion, and it tends to diminish the regard which painting has deservedly received from the world, wherever its highest powers have been engaged; and unjust, because it is contrary to the acknowledgment of ages, and is upheld by no reasoning at all applicable, and scarcely tangible; since, in support of it, he only inquires with a sneer, "what *argument* can be drawn in support of the idea of a future state, from Mr. Barry's picture of final retribution?" Does he not, in this, mistake the ground on which he ought to reason upon painting? If,

by argument, he means its usual acceptation, a deduction from point to point, till we arrive at a satisfactory definition of what is virtue and religion, or what is the probable nature of that future state of existence which man is destined to partake of: then we answer, that no *argument* in proof is expected from the art, none desired of it. The painter's business was to make that future state, the belief of which was already settled, as engaging as possible; to exemplify it in an attractive manner, and make beholders anxious to participate in its glory; and the enquiry ought to have been, has Mr. Barry effected that purpose? We do not hesitate to say, that in the point of invention he undoubtedly has. Who, beholding the assemblage of illustrious characters which he has introduced in that picture, upon a most judicious ground of reasoning, *viz.* their usefulness to mankind, is not led to serious reflection, and an ardent wish to unite with them, to be ranked with the great and good, and emulous to merit such exaltation; to share their conversation; to receive their instruction; and to adore in their enlightened society, that beneficent Creator whose incomprehensible greatness and goodness made and sustains the universe. Such was, such alone could be, the just object of the painter; and no attempt to prove the fact, whether this "corruptible shall put on incorruptible" or not; for that the Christian resorts to his Testament, and the heathen and the philosopher to nature. The artist can only exemplify it, and enlarge our consideration of that state wherein rational beings may be supposed to enjoy the highest possible degree of felicity; and in this respect Mr. Barry is borne out in the opinion he has endeavoured to illustrate, by the writings of many ingenious divines.

To say, what indeed is not said, but must almost necessarily be inferred, that no impression could be made upon the mind of an observer, favourable to virtue and religion by the contemplation of that picture, would be to say, that he either was incapable of reflection, or that by vice and sensuality he was become ill fitted to receive such impressions as it is calculated to produce upon well regulated minds; common experience is against it, and hundreds have left the room where it hangs with as serious and useful emotions, as a sermon on the subject would produce. Many have expressed these sentiments to the writer of this article; and he himself takes his opportunity of paying a grateful tribute of respect to the memory of Mr. Barry, whilst he acknowledges the lasting impression it made upon his mind, when he saw it in early life. Thus although the avowed truism, that virtuous conduct is the wisest and best that man can pursue for his own happiness, will find no *argument* in the pencil for its support; it will have a most able assistant, by the exhibition it is capable of affording of its effects. Is the moral or religious effect of painting, when duly appreciated and exercised, to be denied, when, as we have stated, such works as Hogarth's exist? and is that to take place first of all in the country where he was born, and exerted his useful talents?—He, whose pencil inculcates so powerfully the value of good, and the enormity of evil, and by the representation of the common events of life, brings home the sentiments of morality to every mind, and makes so forcible an appeal to the heart and head of every man possessed of ordinary understanding, be his state in life what it may; not, we will venture to say, to the exception of the learned author himself, whose ungentle sentiment towards the art is the cause of these remarks;—a sentiment whose object, or whose effect at least, if it have any, can only be to restrict the pencil from its most honourable and most valuable application; and render it a mere instrument of amusement, or of idle and useless gratification, or worse.

PICTURE.

The appeal of the pencil is not so much to the understanding, as to the heart and mind; by that the first excitement is produced, and thence necessarily follow reflections, attached to the nature of the images presented to the eye. Do we not fearfully acknowledge its power to corrupt young minds, and take constant care to keep improper drawings from their view? What mode of information does it pursue in this case, but that of presenting images of agreeable vices in an engaging manner? And is it allowed to be so sufficiently potent for the production of evil, that all our care is requisite to counteract or prevent its influence in that respect, and shall it be denied any influence in the promotion of good! forbid it reason, sense, and justice! If the objection to its utility be just, how shall we estimate the wisdom of those whom the learned author alluded to sufficiently honours on other occasions; of those who employed sculpture and painting as political and religious agents, to stimulate the ardent minds of the Greeks to heroism or devotion. The opinions of almost all ancient authors who have noticed it, are most decidedly in favour of the utility of the pencil; and those of the wisest politicians among the moderns have been amply illustrated by the use they have made of its powers.

If any thing can most effectively contribute to strengthen the disinclination of the government of our own country, towards the employment of painting in a way more worthy of its powers than portraiture, it is remarks of this nature, originating with men of acknowledged talent, of great acquirements, and partial devotion to the arts; and which, while they are so guarded as to be capable of justification in their author's peculiar view; yet leave an impression on the reader, much more widely effective in preventing or destroying the energies of the art, than he perhaps intended. But Dr. Johnson is reported to have said, that "he never could see any connection between the historical relation of a fact, and a picture of it;" and perhaps the author alluded to may have some similar diversity from the majority of mankind with regard to moral culture, which prevents him from regarding pictures in a moral or instructive point of view.

PICTURE, *Pictura*, a piece of painting, or a subject represented in colours, on canvas, wood, or the like; and inclosed in a frame.

Pictures or paintings in oil are preserved by coating them with some transparent and hard substance, as a varnish, in order to secure the colours from the injuries of the air or moisture; and to defend the surfaces from scratches or any damages the painting might receive from slight violence. The substances that have been, or may be used for this purpose, are gum arabic, dissolved in water, with the addition of sugar or sugar-candy, to prevent its cracking; glair or whites of eggs, mixed with a little brandy or spirit of wine, in order to make it work more freely, and a lump of sugar to prevent its cracking; isinglass-size, used as either of the former, or mixed with a fourth or fifth of its weight of honey or sugar, and varnishes formed of gum resins dissolved in spirit of wine, or oil of turpentine, which last are called oil-varnishes.

Paintings in miniature are preserved by plates of glass, or the talc called isinglass, placed before them in the frame. Paintings in distemper may be rendered more durable, and preserved from foulness by varnishing them with hot size, boiled to a strong consistence, in which a fifteenth or twentieth part of honey has been dissolved. Crayons must be preserved in the same manner with paintings in water colours, by plates of glass or isinglass.

When pictures are cut or torn, they may be repaired by

laying them on an even board or table, carefully putting together the torn or divided parts with colour laid as a cement, in and over the joint, and keeping them in the situation till the cement is thoroughly dried. The protuberance of the cement may be easily reduced with a penknife, and the repaired part properly coloured so as to correspond with the picture. When part of the cloth is destroyed, a piece of canvas somewhat bigger than the vacant space is to be plattered over on the outside of the cloth with white or any other colour, and when it is thoroughly dry, the inequality of the picture in this part is to be filled up with the same matter, and properly reduced and coloured.

The art of cleaning pictures and paintings is of great consequence in order to their preservation: in this operation great skill and care are requisite, so that the menstruum used for taking off any foulness may not dissolve the oil in the painting itself, or disorder its colours, and that each sort of varnish with which paintings are coloured may be taken off without injury to the painting. The first and most general substance used for cleaning pictures is water, which will remove any foulness arising from many kinds of glutinous bodies, as sugar, honey, glue, &c. and any varnish of gum arabic, glair of eggs or isinglass, without affecting the oil that holds the colours together. Olive oil or butter will dissolve pitch, resin, and other substances of a like kind, without injuring the oil of the painting. Pearl-ashes, dissolved in water, form a proper menstruum for most kinds of matter that foul paintings; but they must be very cautiously used, as they will corrode the oil of the painting, if there be no varnish of the gum resins over it. Soap is of the same nature, and should be cautiously applied, and only to particular spots, that elude all other methods. Spirit of wine will dissolve all the gums and gum resins, except gum arabic, and is therefore very necessary for taking off from pictures varnishes composed of such substances, but it also corrodes the oil of the painting. This is also the case with oil of turpentine, and essence of lemon, spirit of lavender, and rosemary, and other essential oils. With regard to paintings that are varnished with gum arabic, glair of eggs, or isinglass, the varnish should be taken off when they are to be cleaned. This may be easily distinguished by wetting any part of the painting, which will feel clammy, if varnished with any substance soluble in water. This kind of varnish may be taken off with hot water and a sponge, or by gentle rubbing with a linen cloth dipped in warm water. If paintings, on this trial, appear to be varnished with gum resins, or such substances as cannot be dissolved in water, they may, in some cases, be sufficiently cleaned by a sponge with warm water; and any remaining foulness may be removed by rubbing the painting over with olive oil made warm, or with butter, which should be wiped off with a woollen cloth; and if the picture require farther cleaning, wood-ashes or pearl-ashes may be used in the following manner: take an ounce of pearl-ashes, and dissolve them in a pint of water; or take two pounds of wood-ashes, and stir them well in three quarts of water, once or twice in an hour for half a day. Then pour off the clear fluid, and evaporate it to a quart or three pints; wash the painting well with a sponge dipped in either of these leys, and rub gently any foul spots with a linen cloth till they disappear. If this method fail, recourse must be had first to spirit of wine, then to oil of turpentine, and if these are ineffectual, the essence of lemons; with either of which the foul spots should be slightly moistened, and the part immediately rubbed gently with a linen cloth. After a little rubbing, if oil of turpentine or essence of lemon has been applied, olive oil should be put upon the spot;

spot; and water, if spirit of wine has been used; which should be taken off with a woollen cloth; repeating the operation till the foulness be removed. When paintings appear to have been varnished with those substances that will not dissolve in water, and after the use of the above means retain their foulness, the following method will succeed: place the picture or painting in a horizontal situation; and moisten, or rather flood, by means of a sponge, the surface with very strong rectified spirit of wine: keep the painting thus moistened, by adding fresh quantities of the spirit, for some minutes; then flood the whole surface copiously with cold water; wash off the whole without rubbing; and when the painting is dry, repeat the operation till the whole varnish is taken off. *Handm. to the Arts, vol. i. p. 224. 245.*

PICTURES, or Paintings, in Oil, Method of taking off, &c. The art of removing paintings in oil, from the cloth or wood on which they are originally done, and transferring them to new grounds of either kinds of substance, is of great use. For those on cloth or canvas, the method is as follows: let the decayed picture be cleansed of all grease that may be on its surface, by rubbing it very gently with crumb of stale bread, and then wiping it with a very fine soft linen cloth. It must then be laid, with the face downwards, on a smooth table covered with fan-paper, or the India-paper; and the cloth on the reverse must be well soaked with boiling water, spread upon it with a sponge, till it appears perfectly soft and pliable. Turn the picture with the face upwards, and having stretched it evenly on the table, pin it down with nails at the edges. Having melted a quantity of glue and strained it through a flannel cloth, spread part of it, when a little stiffened, on a linen cloth of the size of the painting, and when this is set and dry, lay another coat over it; when this becomes stiff, spread some of the glue, moderately heated, over the face of the picture, and lay over it the linen cloth already prepared in the most even manner, and nail it down to the picture and table. Then expose the whole apparatus to the heat of the sun, in a place where it may be secured from rain, till the glue be perfectly dry and hard; when this is the case, remove the picture and linen cloth from the table. Turn the picture with the face downwards, and let it be stretched and nailed to the table as before; then raise round its edge a border of wax, as in the etching of copper-plates, forming a kind of shallow trough with the surface of the picture; into which pour a proper corroding fluid, as oil of vitriol, aqua fortis, or spirit of salt, but the last is to be preferred: dilute either of these with water to such a degree, determined by previous trials, that they may destroy the threads of the original canvas or cloth of the picture, without discolouring it. When the corroding fluid has answered this purpose, drain it off through a passage made at one end of the border of wax, and wash away the remaining part by repeatedly pouring quantities of fresh water on the cloth. The threads of the cloth must be then carefully picked out till the whole be taken away. The reverse surface of the painting, being thus wholly freed from the old cloth, must be well washed with water by means of a sponge, and left to dry. In the mean time prepare a new piece of canvas of the size of the painting; and having spread some hot glue, purified as before, and melted with a little brandy or spirit of wine over the reverse of the painting, lay the new canvas evenly upon it while the glue is hot, and compress them together with thick plates of lead or flat pieces of polished marble. When the glue is set, remove these weights, let the cloth remain till the glue is become perfectly dry and hard. Then the whole must be again turned with the other side upwards, and the border of wax being

replaced, the linen cloth on the face of the painting must be destroyed by means of the corroding fluid; particular care is necessary in this part of the operation; because the face of the painting is defended only by the coat of glue which cemented the linen cloth to it. The painting must then be freed from the glue by washing it with hot water, spread and rubbed on the surface by a sponge. The painting may afterwards be varnished as a new picture; and if the operation be well conducted, it will be transferred to the new cloth in a perfect state.

When the painting is originally on wood, it must first be detached from the ceiling or wainscot where it was fixed; and the surface of it covered with a linen cloth, cemented to it by means of glue, as already directed. A proper table being then provided, and overspread with a blanket, or thinner woollen cloth, laid on in several doubles; the painting must be laid upon it with the face downwards, and fixed steady; and the board or wood on which it was done must be planed away, till the shell remains as thin as it can be made, without damaging the paint under it. The process is afterwards the same as that in the case of paintings on canvas, till the painting on wood be in like manner transferred to a cloth or canvas. *Doffie's Handm. to the Arts, vol. ii. p. 417, &c.*

PICTURE, Magical. See *MAGICAL*.

PICTURESQUE BEAUTY, according to a late elegant writer, refers to "such beautiful objects as are suited to the pencil." This epithet is chiefly applied to the works of nature, though it will often apply to works of art also. Those objects are most properly denominated picturesque, which are disposed by the hand of nature with a mixture of *varied rudeness, simplicity, and grandeur*. A plain neat garden with little variation in its plan, and no striking grandeur in its position, displays too much of art, design, and uniformity, to be called picturesque. "The idea of neat and smooth (says Mr. Gilpin), instead of being picturesque, in fact disqualify the object in which they reside from any pretensions to picturesque beauty. Nay, farther, we do not scruple to assert, that roughness forms the most essential point of difference between the beautiful and the picturesque; as it seems to be that particular quality which makes objects chiefly pleasing in painting. I use the general term *roughness*; but, properly speaking, roughness relates only to the surfaces of bodies: when we speak of their delineation, we use the word *ruggedness*. Both ideas, however, equally enter into the picturesque, and both are observable in the smaller as well as in the larger parts of nature; in the outline and bark of a tree, as in the rude summits and craggy sides of a mountain.

"Let us then examine our theory by an appeal to experience, and try how far these qualities enter into the idea of picturesque beauty, and how far they mark that difference among objects which is the ground of our inquiry.

"A piece of Palladian architecture may be elegant in the last degree; the proportion of its parts, the propriety of its ornaments, and the symmetry of the whole, may be highly pleasing; but if we introduce it in a picture, it immediately becomes a formal object, and ceases to please. Should we wish to give it picturesque beauty, we must use the mallet instead of the chisel; we must beat down one-half of it, deface the other, and throw the mutilated members around in heaps; in short, from a smooth building we must turn it into a rough ruin. No painter who had the choice of the two objects would hesitate a moment.

"Again, why does an elegant piece of garden-ground make no figure on canvas? The shape is pleasing, the combination of the objects harmonious, and the winding of the

walk in the very line of beauty. All this is true ; but the smoothness of the whole, though right and as it should be in nature, offends in picture. Turn the lawn into a piece of broken ground, plant rugged oaks instead of flowering shrubs, break the edges of the walk, give it the rudeness of a road, mark it with wheel tracks, and scatter around a few stones and brushwood : in a word, instead of making the whole smooth, make it rough, and you make it also picturesque. All the other ingredients of beauty it already possessed." On the whole, picturesque composition consists in uniting in one whole, a variety of parts, and these parts can only be obtained from rough objects.

It is possible, therefore, to find picturesque objects among works of art, and it is possible to make objects so ; but the grand scene of picturesque beauty is nature in all its original variety, and in all its irregular grandeur. " We seek it (says our author) among all the ingredients of landscape, trees, rocks, broken grounds, woods, rivers, lakes, plains, valleys, mountains, and distances. These objects in themselves produce infinite variety ; no two rocks or trees are exactly the same ; they are varied a second time by combination ; and almost as much a third time by different lights and shades and other aerial effects. Sometimes we find among them the exhibition of a whole, but oftener we find only beautiful parts."

Sublimity or grandeur alone cannot make an object picturesque : for, as our author remarks, " however grand the mountain or the rock may be, it has no claim to this epithet, unless its form, its colour, or its accompaniments, have some degree of beauty. Nothing can be more sublime than the ocean ; but wholly unaccompanied, it has little of the picturesque. When we talk, therefore, of a sublime object, we always understand that it is also beautiful ; and we call it sublime or beautiful only as the ideas of sublimity or simple beauty prevail. But it is not only the form and the composition of the objects of landscape which the picturesque eye examines, it connects them with the atmosphere, and seeks for all those various effects which are produced from that vast and wonderful storehouse of nature. Nor is there in travelling a greater pleasure than when a scene of grandeur bursts unexpectedly upon the eye, accompanied with some accidental circumstance of the atmosphere which harmonizes with it, and gives it double value."

There are few places so barren as to afford no picturesque scene.

" ————— Believe the muse,
She does not know that inauspicious spot
Where beauty is thus niggard of her store.
Believe the muse, through this terrestrial waste
The seeds of grace are sown, profusely sown,
Even where we least may hope."

Mr. Gilpin mentions the great military road between Newcastle and Carlisle as the most barren tract of country in England ; and yet there, he says, there is " always something to amuse the eye. The interchangeable patches of heath and green-sward make an agreeable variety. Often, too, on these vast tracts of intersecting grounds we see beautiful lights, softening off along the sides of hills ; and often we see them adorned with cattle, flocks of sheep, heath-cocks, grouse, plover, and flights of other wild-fowl. A group of cattle standing in the shade on the edge of a dark hill, and relieved by a lighter distance beyond them, will often make a complete picture without any other accompaniment. In many other situations also we find them wonderfully pleasing, and capable of making pictures amidst all the deficiencies of land-

scape. Even a winding road itself is an object of beauty ; while the richness of the heath on each side, with the little hillocks and crumbling earth, give many an excellent lesson for a fore-ground. When we have no opportunity of examining the grand scenery of nature, we have every where at least the means of observing with what a multiplicity of parts, and yet with what general simplicity, she covers every surface.

" But if we let the imagination loose, even scenes like these administer great amusement. The imagination can plant hills ; can form rivers and lakes in valleys ; can build castles and abbeys ; and if it find no other amusement, can dilate itself in vast ideas of space."

Mr. Gilpin, after describing such objects as may be called picturesque, proceeds to consider their sources of amusement. We cannot follow our ingenious author through the whole of this consideration, and shall therefore finish our article with a short quotation from the beginning of it. " We might begin," says he, " in moral style, and consider the objects of nature in a higher light than merely as amusement. We might observe, that a search after beauty should naturally lead the mind to the great origin of all beauty ; to the

" ——— first good, first perfect, and first fair."

But though in the theory this seems a natural climax, we insist the less upon it, as in fact we have scarce ground to hope that every admirer of picturesque beauty is an admirer also of the beauty of virtue, and that every lover of nature reflects, that

" Nature is but a name for an effect,
Whose cause is God."

If, however, the admirer of nature can turn his amusements to a higher purpose ; if its great scenes can inspire him with religious awe, or its tranquil scenes with that complacency of mind which is so nearly allied to benevolence, it is certainly the better. " *Apponatur lucro.*" It is so much into the bargain ; for we dare not promise him more from picturesque travel than a rational and agreeable amusement. Yet even this may be of some use in an age teeming with licentious pleasure ; and may in this light at least be considered as having a moral tendency."

PICUCULI *de Cayenne*, in *Ornithology*. See GRACULA *Cayennensis*

PICUIPINIMA. See COLUMBA *Passerina*.

PICUS, in *Ornithology*, a genus of birds of the order Picæ ; the generic character is as follows : bill angular, straight, wedged at the tip ; nostrils covered with recumbent straceous feathers ; tongue round, worm-shaped, very long, bony, missile, daggered, beset at the point with bristles bent back ; it has ten tail-feathers, which are hard, rigid, and pointed ; the feet are formed for climbing. The birds of this genus live principally upon insects, to obtain which they climb trees, and are perpetually in search of those crevices in which their food is lodged. These insects they transfix with their missile and daggered tongue, which, when it has obtained its purpose, is, by an almost invisible motion, withdrawn wholly into the mouth. This process is almost incessantly repeated throughout the whole day, with the utmost precision and celerity. Doomed to this perpetual occupation, wood-peckers avoid society, even that of their own species, and appear to possess none of the animation of cheerfulness, or vigour of courage. They have no notes but such as are expressive of pain and sadness, and they seem to lead a life of labour and restlessness. There are nearly sixty species mentioned in Gmelin's last edition of *Linnaeus*.

PICUS.

Species.

* **MARTIUS**, or Great black Wood-pecker. The specific character is black; cap vermilion. This bird inhabits many parts of Europe, as well as our own country; it is also a native in Siberia and Chili; it is found chiefly in the poplar tree; it builds a large deep nest, and lays two or three eggs; it feeds principally on bees and ants, and is about seventeen or eighteen inches long. This bird speedily excavates trees, so as to expose them to be blown down by winds which would not otherwise have affected them. Under the hole made by it, saw-dust and pieces of wood may sometimes be found in pecks.

LIGNARIUS; White-bellied Wood-pecker. Cap vermilion; body barred with white. This is found chiefly in Chili, and is somewhat less than a blackbird.

PRINCIPALIS; White-billed Wood-pecker. Black; crest scarlet; a line on each side the neck and secondary quill-feathers is white. It inhabits America, from New Jersey to Brazil; is about sixteen inches long, and makes spiral holes in the trees.

PILEATUS; Pileated Wood-pecker. Black; crest red, temples and wings spotted with white. It inhabits the woods of North America, and is eighteen inches long; the female of this species has a brown front. There is a variety of which the belly is obscurely barred with white.

LINEATUS; Lineated Wood-pecker. This species is black; crest is scarlet; it has a white line from the bill down the neck, and as far as the middle of the back. It inhabits Cayenne, as does the next, and is nearly fourteen inches long.

RUBRICOLLIS; Red-necked Wood-pecker. Brown, beneath tawny; crested head and neck blood-red.

MELANOLEUCOS; Buff-crested Wood-pecker. Black; body beneath, line on each side the neck, nape and rump white; the hind part of the crest brownish-yellow. It is found in Surinam.

HIRUNDINACEUS; Lesser black Wood-pecker. Black; cap scarlet; shoulders dotted with white. It inhabits North America, and is about five inches and a half long. Two varieties of this species inhabit Cayenne. 1. Middle of the breast red; belly varied with black and grey. 2. Crown with a red spot; area of the eyes is white; the hind-head is golden. Of this last variety the whole head of the female is black; the eye-lids are white.

PASSERINUS; Pafferine Wood-pecker. Yellowish-olive, beneath barred with brown and whitish; is about six inches long, and is found in St. Domingo.

STRIATUS; Rayed Wood-pecker. Black streaked with olive, beneath olive; front, cheeks, chin, throat, and breast grey; crown, hind-head, rump, and upper tail-coverts red. There is a variety that has a black crown; it is nine inches long, and is found in St. Domingo.

MELANOCHLOROS; Gold-crested Wood-pecker. Variegated with black and yellow; the crest is gold; tail is black. It inhabits Cayenne, and is about thirteen inches long. There is a variety that has a black crown; a red crest; the middle tail-feathers are black, the lateral ones are barred with tawny and black.

FLAVESCENS; Yellow-crested Wood-pecker. Black barred with yellow; pendent crest, chin, cheeks, and neck yellow. It is found in Brazil, and is about the size of a jay.

CAYANENSIS. This, as its name imports, is found in Cayenne, and is not quite eight inches long. It is olive-coloured; the feathers towards the tip are marked with a

black spot; the crown, chin, and tail are black; the hind-head is red; the cheeks are whitish; the belly is yellowish.

FLAVICANS; Yellow Wood-pecker. Yellowish, crested; quill-feathers brown; tail black. It inhabits Cayenne, as do the next two. The male bird has a maxillary band.

CINNAMOMEUS; Ferruginous Wood-pecker. Cinnamon colour, with a few yellowish spots; the crest and lower part of the back yellow; the tail is black.

MULTICOLOR; Black-breasted Wood-pecker. This species is crested; rufous; beneath pale rusty; head, chin, and neck orange; nape, throat, breast, and spots on the wings black.

ERYTHROCEPHALUS; Red-headed Wood-pecker. Head wholly red; wings and tail black; the belly is white. It is found in North America, and is nine inches and a half long; it migrates and feeds on acorns, fruit, and Indian corn. From the visits of this bird, the natives are enabled in a measure to foretell the rigour or clemency of the approaching winter. This species is extremely destructive to maize fields and orchards. During winter they are very tame, and sometimes come into houses, as the robin does with us. They are found chiefly in old trees, and the noise which they make with their bills, may, when the air is calm and still, be heard at the distance of a mile and more.

RUBER; the Red-breasted Wood-pecker. Head, neck, and breast red; back and wings black; belly ochre. It is found at Cayenne.

OBSCURUS; White-rumped Wood-pecker. Dusky, streaked and waved with whitish; beneath it is white; first quill-feathers black, secondary white, with two black bars. It inhabits Long island, and is nine inches long.

FASCIATUS; Striped-bellied Wood-pecker. The colour of this species is black; the crown, lores, and sub-maxillary band are scarlet; the belly is streaked white and black; tail-feathers white at the tip.

AURANTIUS; Orange Wood-pecker. Above orange; nape, rump, and tail black; is about ten inches long, and is found at the Cape of Good Hope.

SENEGALENSIS; Gold-backed Wood-pecker. Front and cheeks are brown; cap red; back and quill-feathers reddish-gold; body beneath grey, undulate with brown and white. It is found in Senegal, and is scarcely larger than a sparrow.

CAPENSIS; Cape Wood-pecker. This, as its name signifies, is found in the Cape of Good Hope, and is less than our lark; it is grey; the back, neck, and breast are olive; the quill-feathers are dusky; rump and upper tail-coverts red; tail-feathers black. There is a variety that has its back and wings olive-brown; cap, rump, and belly red.

AURATUS; Gold-winged Wood-pecker. Striated transversely with black and grey; the chin and breast black; the nape is red, and the rump is white. It is found in North America, and is almost continually on the ground; it feeds on worms and insects, and when these are not to be had, on berries and grubs. When fat it is esteemed excellent food. It migrates to Hudson's Bay, and it does not climb trees.

CAFER; Gold-winged Wood-pecker. Above brown, beneath claret, dotted with black; wings beneath, and shafts of the wings and tail, vermilion. It is found at the Cape of Good Hope.

OLIVACEUS; Crimson-breasted Wood-pecker. This species is olive; neck beneath, breast and rump pale red; chin, throat, quill-feathers and vent dusky brown; the tail above is black.

CAROLINUS; Carolina Wood-pecker. Cap and nape red; back with black bands; middle tail-feathers white, dotted

PICUS.

dotted with black, the rest black. There are three varieties of this species. 1. Front and cheeks pale brown; belly pale yellowish-brown. 2. Spots on the chin and under the eyes red. 3. Black and white; cap, nape, and belly red; front and neck beneath yellow-grey; sides of the neck from the mouth with a black line.

UNDATUS; Red-cheeked Wood-pecker. Testaceous waved with black; temples blood-red. It inhabits Guiana and Surinam, as do the two following.

RUFUS; Rufous Wood-pecker. Rufous waved with black; wings, tail, and body beneath deeper. A variety has a black breast; and under the eyes a black spot.

CHLOROCEPHALUS; Yellow-headed Wood-pecker. Olive, beneath spotted with white; neck and subcrested head yellow; crown red. This is six inches long.

MINIATUS; Red-winged Wood-pecker. Crested, red, beneath white; throat rosy; bill and tail blue; tail-coverts green. This is nine inches long, and is found in Java.

MALACCENSIS; Malacca Wood-pecker. Crested head and shoulders scarlet; chin and throat rufous yellow; body beneath barred with black and white; the tail is black. It is found in Malacca, as its name imports.

PITIU. Brown dotted with white; the tail is short. It inhabits Chili; has the appearance of a pigeon, and builds, not in the hollows of trees, but on the banks of rivers and declivities of mountains; it lays usually four eggs.

* **VIRIDIS**; Green Wood-pecker. Green; crown crimson. This is the largest species found in England, and is full thirteen inches long. These birds are frequently seen on the ground, particularly where ant-hills abound, the population of which they extirpate by their incessant efforts. This bird will occasionally not be contented with darting its tongue at them singly, but by the combined exertion of its bill and feet lays open the whole nest, and commits the most wholesale ravage upon the ants and their eggs. There is a variety found in Mexico, full thirteen inches long; of which the upper part of the head and spots beneath the ears are deep red; the rump is of a pale yellow. It makes a circular hole in the dead part of trees for its nest, and lays five or six greenish coloured eggs spotted with black; it is remarkably fond of bees.

BENGALENSIS; Bengal Wood-pecker. Green; crest red; nape black; front and throat variegated white and black; body beneath white. It is eight inches and a half long, and is found in Bengal. A variety of this species is a little larger, and inhabits Ceylon and China. Its head is marked with numerous white spots; the back is black, and scarlet in the middle.

QUADRIMACULATUS; Blue-throated Wood-pecker. Green; beneath blueish; crown and rump yellow; throat, quill and tail-feathers black. This is the size of the *Viridis*, and is found in Ceylon.

PHILIPPINARUM; Philippine Wood-pecker. The size of the last, and found in Manila. It is brown-green; crested; beneath spotted with white and black; the rump is red; the tail-feathers have two white spots.

GOENSIS; Goa Wood-pecker: Green, beneath whitish; crown and crested hind-head red; tail and fillet reaching from the eyes to the wings black; the wings are golden. It is found in Goa, and is very similar to the *Bengalensis*.

MANILLENSIS; Manila green Wood-pecker. Dirty-green; crown covered with grey; wings and tail blackish; upper tail-coverts red. It is found in Manila.

GARTAN; Crimson-rumped Wood-pecker. Above grey-brown, beneath yellowish-grey; wings with dirty spots; crown and rump red. It is found in Senegal, and is a good deal less than the *Viridis*.

CANUS; Grey-headed green Wood-pecker. Cinereous,

front obscurely spotted with red; back, shoulders, wing and tail-coverts green; rump yellow; wings and tail brown; chin whitish. It inhabits Norway, Russia, and Siberia.

PERSICUS; Persian Wood-pecker. Pale yellow; body above, tips of the quill-feathers, and area of the eyes, ferruginous. It is a native of Persia.

SEMIROSTRIS; Half-billed Wood-pecker. Brown-ash, beneath white; head brown, spotted with yellowish; upper mandible shorter. It is only of the size of a martin.

PUBESCENS; Downy Wood-pecker. Back longitudinally downy; outer tail-feathers white, with four black spots. The male bird has the hind-head red. It is found in Carolina, Virginia, and other parts of North America, and is a very daring bird, and particularly mischievous to fruit-trees in orchards. As soon as it has pecked one hole in a tree, it makes another close to the first, in a horizontal direction, proceeding till it has made a circle of holes quite round the trunk, so that the tree frequently dries up and decays.

VILLOSUS; Hairy Wood-pecker. Back somewhat downy, in a longitudinal direction; the outer tail-feathers are entirely white. It is from nine to twelve inches long. Like the *Pubescens*, it is a sad pest to orchards. It inhabits North America, from Hudson's Bay to Carolina, and it has been seen in the north of England.

* **MAJOR**; Greater spotted Wood-pecker. Variegated with black and white; the vent and hind-head are red. This is also called the witwall, is nine inches long, and strikes with far greater comparative force against the trees than any of the tribe. It creeps with facility over the branches in every direction; and when any person attempts to observe it on one side of a branch, it passes to the opposite with extreme celerity, repeating this change in correspondence with every renewed effort of the enemy. It inhabits many parts of Europe, as well as England; here indeed it is less frequent than the *Viridis*, to which it is closely allied in manners and habits, except that it rarely descends to the ground in search of food. It lays four or five glossy eggs in the decayed wood, without any formal preparation of a nest.

* **MEDIUS**; Middle spotted Wood-pecker. Variegated with white and black, the vent and cap are red. It is doubted if this be a distinct species, or whether it be not the young of the *Major* just described.

* **MINOR**; Lesser spotted Wood-pecker. This species is also variegated with white and black; the crown is red, and the vent testaceous. It is found in divers parts of Europe and Asia. It has the habits of the *Major*, but is much more rarely seen. There are two varieties; 1. Crown, nape and scrag black-grey; body beneath yellowish, spotted with black. This is a native of Panay. 2. Hind-head subcrested; crown with a crimson spot; front, cheeks, and body beneath white. It is found in Ceylon.

TRICOLOR; Varied Wood-pecker. Black, with white transverse streaks; breast and belly red. It inhabits New Spain.

CANADENSIS; Canada spotted Wood-pecker. White; crown, back, shoulders, and the two middle tail-feathers black, the other tail-feathers and wings varied with black and white. It is a native of Canada, and nine inches long.

VARIUS; Yellow-bellied Wood-pecker. Variegated black and white; crown red; vent white, barred with brown. It inhabits North America; nine inches long; it is a very numerous tribe, and extremely destructive to corn and fruits.

FLAVIPES; Yellow-legged Wood-pecker. Black, beneath white; legs yellow.

BICOLOR; the Encenada Wood-pecker. Varied with

grey and white; sides of the crested head white; quill-feathers brown, spotted with white. The female bird is totally brown, with a crest.

CARDINALIS; *Cardinalis* Wood-pecker. Black, beneath white, spotted with black; the crown and hind-head red. Found in Luzonia; and is the size of the *Viridis*.

NUBICUS; Nubian Wood-pecker. Variegated with white, rufous, and brown; crown black, spotted with white; hind-head subcrested; red breast, whitish, with black dots; tail with rufous brown lines. It is found in Nubia, and is seven inches and a half long.

MOLUCCENSIS; Brown Wood-pecker. Black, waved with white; beneath whitish, arrow-streaked with brown; quill and tail-feathers brown, spotted with white. It inhabits the Molucca islands. There is a variety black-brown, spotted with white; beneath and head white; crown and spot beneath the eyes brown. It inhabits India, and is five inches long.

MINUTUS; Minute Wood-pecker. This, the least of all the tribe, is found in Cayenne. It is chestnut-grey; beneath whitish waved with brown; crown red; hind-head black, spotted with white.

TRIDACTYLUS; Three-toed Wood-pecker. Variegated black and white; three-toed; a variety is also variegated black and white; and white beneath. The *first* inhabits America, Europe, and Sicily: the *second* is found in Cayenne.

PICUS Cinerus. See *SITTA Europea*, *S. jamaicensis*, and *S. major*.

PICUS Imbricatus, or *Picus Principalis* of Linnæus, the name of an American bird, described by Nieremberg, and called by the natives *quatotomini*. It is of the size of the hoopoe, and is variegated with black and brown; it is of the wood-pecker kind, having a beak three fingers breadth long, with which it perforates trees: its head is small and red, and has a fine red crest; but the feathers are black on their upper side; it has on each side of the neck a broad white line, reaching to the breast; its legs and feet are of a blueish colour; it builds in high trees, and is principally found near the shores of the South sea. It feeds on insects. See **PICUS**.

PICUS Major Leucophaeus. See **CUCULUS Vetula**.

PICUS Murarius, the name of a bird called in English the *wall-creeper*, and improperly ranked among the *pici*, as wanting many of the characters of that genus: and therefore classed in the Linnæan system under the genus of *certhia*, or creeper. It is about the bigness of the common sparrow; its bill is black, slender, and long; its head, neck, and back grey; its breast white, and its wings partly grey and partly red; its tail is short and black; its long wing-feathers also, and the lower part of its belly, and its legs, are of the same colour; its legs are short, but its feet are not placed as in the wood-pecker; but are three before and one behind; it is very common in Italy, Germany, and some parts of France; it is a very lively and cheerful bird, and as the common wood-pecker climbs trees and feeds on the insects in their cracks, so this bird runs up old walls, and feeds on what it finds in the cracks of the stones.

PICUS Nidum Suspendens, a name by which some authors have called the *galbula*; a yellow bird of the thrush kind, very remarkable for its beauty, and for the structure and manner of hanging its nest. See **ORIOLES Galbula**.

PICUS Salutiferus, the name under which Nieremberg has described a Mexican bird, called by the natives *henquechol-total*.

It is of the size of the common black-bird, and has a long and black beak: its head and a great part of its neck

are red; its breast and belly are grey, and it has a crest of red feathers upon its head. It is of the wood-pecker kind, and has its name from the supposed virtue of its feathers, particularly those of the crest, in curing the head-ach.

PIDAURA, in *Geography*, a town of the Morea, anciently called "Epidaurus," situated on the W. coast of the gulf of Engia; 35 miles E. of Napoli di Romania. N. lat. 37° 40'. E. long. 23° 24'.

PIDISJARVI, a town of Sweden, in the government of Ulea; 48 miles E. of Gamla Karleby.

PIE, in *Agriculture*, a provincial term applied to signify a receptacle for preserving potatoes, turnips, and other roots. And when these are for potatoes they are usually formed with dry earth in a dry situation, being made in the ridge or conical form.

Pies are likewise made use of for curing rape-seed, being built in the field with platted itraw. The form, according to Mr. Marshall, is that of a corn bushel, the diameter seven or eight feet, the height three or four feet. This large straw basket-like receptacle is filled with rough feed to the brim, topped up in a conical form with straw, and the whole secured with a coat of thatch. This is mostly done when the markets are bad at the period of thrashing, as the feed may be preserved any length of time in these pies, if there is a sufficiency of pulls among it, and the quantity of feed deposited in them be not too large. It is at present a practice seldom employed.

PIECE, in *Commerce*, signifies sometimes a whole, and sometimes only a part of the whole.

In the first sense we say, a piece of cloth, of velvet, &c. meaning a certain quantity of yards, regulated by custom, being yet entire, and not cut.

In the other signification we say, a piece of tapestry; meaning a distinct member wrought apart, which, with several others, make one hanging.

A piece of wine, of cyder, &c. is a cask full of those liquors.

PIECE, Chimney. See **CHIMNEY**.

PIECE, Detached. See **DETACHED**.

PIECE, Easel. See **EASEL**.

PIECE-Goods, in *Commerce*, a name given in India to the various fabrics of manufactured cotton.

PIECE, Master. See **MASTER**.

PIECE, in *Coinage* and *Commerce*, signifies sometimes the same thing with *species*: as when we say this piece is too light, &c.

Sometimes, by adding the value of the pieces, it is used to express such as have no other particular name: as a piece of eight rials, a piece of twenty-five sols, &c.

In England, the piece, absolutely, is sometimes used for twenty shillings sterling, and sometimes for a guinea.

By 6 Geo. II. cap. 25. broad-pieces, of five-and-twenty, or three-and-twenty shillings value, or any halves or quarters thereof, are called in. And all persons are forbid to receive or utter them in payment by tale.

PIECE of Eight denotes the Spanish dollar or peso, which in foreign exchanges is valued at 8 reals of old plate or 15 reals 2 maravedis vellon: but in commercial transactions within the country, it is reckoned at 15 reals vellon.

As a silver coin, the dollar, or peso duro, since the coinage of 1772, passes for 20 reals vellon, and the half dollar, or escudo vellon, for 10. This dollar contains 374½ troy grains of fine silver, or 405½ grains of English standard silver; and therefore its value in English silver coin is 4s. 4½d.; and the half dollar in proportion. The value of the peso of plate, or dollar of exchange, in English silver coin, is 39½d.; but if allowance be made for remedy in coinage, it must be valued in the dollar at ½ sterling. By the assay

affay at the London mint, the weight of the dollar is 17 dwt. 8 gr., and its fineness 8 dwt. worse than English standard: hence its value in English silver coin is 4s. 3 $\frac{3}{4}$ d.

The average weight of 1000 dollars at the Bank of England is found to be 866 ounces troy.

The Spanish dollars coined since 1772 have the following impressions: head of the reigning king, with his name and DEI GRATIA; reverse, arms of Spain; which, on pieces coined at Mexico, stand between two pillars with NE PLUS ULTRA: legend round the piece, HISPAN. ET IND. REX, with an M. for Mexico; 8 R. for eight reals, and the initials of the moneyer's name: these are commonly called Pillar dollars; but those coined in Europe have no pillars; and the legend is only, HISPANIARUM REX. The initials are not at the end of the legend, but by the side of the escutcheon in place of the pillars. The divisions of the dollar bear the same impressions; but the half dollar is marked 4 R.

In the Danish islands, St. Thomas, St. John, and Santa Cruz, accounts are kept in piastres or rix-dollars current (also called pieces of eight), each rix-dollar being divided into eight schillings or bits, and each bit into six stivers. Accounts are also kept in dollars of 100 cents, as in America. The Spanish dollar passes here for 12 $\frac{1}{2}$ bits, and each bit for 6 $\frac{3}{4}$ stivers. Kelly's Universal Cambist. See COIN and EXCHANGE.

PIECE is also a kind of money of account, or rather a manner of accounting, used among the negroes on the coast of Angola, in Africa.

The price of slaves, and other commodities here negotiated, as also the duties paid the petty kings, are estimated on both sides in pieces. Thus those barbarians requiring ten pieces for a slave, the Europeans, in like manner, value the money, or merchandise, to be given in exchange, in pieces.

PIECE, in *Heraldry*, denotes an ordinary, or charge.

PIECES, in the *Military Art*, include all sorts of great guns and mortars.

These are also called *pieces of ordnance*, or *artillery*.

PIECES, *Field*. See FIELD-PIECES.

PIECES, *Battery*. See GREAT GUNS.

PIECES, *Garrison*. See GARRISON.

PIECE, *Poisoning a*. See POISON.

PIECE, *Soldier's*. See FIRELOCK.

PIECE, *Elevation of a*. See ELEVATION.

PIECE, *Quadrating of*. See QUADRATING.

PIECE-Work, in *Rural Economy*, that sort which is done by the great or piece. It is sometimes called task-work. This mode of working is becoming more general and necessary daily on account of the increasing price of labour; but in letting it, it requires that the farmer should be well acquainted with its nature, and the time it will take in performing it, or he will be liable to much imposition: he should likewise be a good judge of the proper manner of performing the work. Some are of opinion that the work is never so well done in this way. See WORK.

PIED, *Fr*. See FOOT.

PIED, or *ped de Roi*, is the French foot in the old system. See FOOT and MEASURE.

PIEDE, or PIETE', *La*, in *Geography*, a town of Mexico.

PIEDI OREZZA, a town of the island of Corfica; 12 miles E.N.E. of Corte.

PIEDICORTE, a town of Corfica; 12 miles E.S.E. of Corte.

PIEDMONT, the most extensive province in the northern part of Italy, about 150 English miles in length by 100 of medial breadth. It is bounded on the N. by the Valais, on the E. by the duchies of Milan and Montferrat,

on the S. by the country of Nice and the territories of the Genoeve, and on the W. by Savoy. This principality was first inhabited by Umbrians, Etrurians and Ligurians, and afterwards by Gauls, upon their establishment in Italy, under Brennus, &c. which gave occasion to its being called "Cisalpine Gaul," or "Gaul on this side of the Alps," with regard to Rome. It became in a subsequent period a part of Lombardy, and in the 13th century formed a portion of the gradual acquisitions of the counts afterwards dukes of Savoy, and latterly kings of Sardinia. It is said to have derived its name from its situation "ad pedem montium." With regard to its revenue, when that of Sardinia was estimated at 1,085,000*l.*, Piedmont contributed 953,750*l.*, Savoy 87,500*l.*, and Sardinia only 43,750*l.* This province is pleasant and fruitful, and the air mild and pure: the plains produce in abundance wheat, maize, rice, with some olives and wine, and the pasturages feed large herds of cattle. The soil is a rich sandy loam, with some tracts of large gravel brought down from the rivers; but the heat is excessive in summer, and the winter cold very severe; and yet the silk is esteemed of the finest quality. Around Turin, and through a great part of the province, artificial irrigation, or the watering of meadows, is practised with great assiduity and success. The surrounding Alps are rich in minerals, and they supply numerous streams which fertilize the plains. In the duchy of Aosta, the mines of copper, accompanied with antimony, arsenic, and zinc, are numerous: and in the superior regions near Macuguaga, there are mines of gold, found in marcasite and quartz; in the vale of Sefia are the gold mines of St. Maria and Cavavechia, also containing silver. Gold is likewise found in the mountains of Challend near the vale of Aosta; and the torrent Evenfon rolls down pebbles of quartz, veined with that precious metal. Not far to the E. of Mont Blanc, a rich vein of cobalt has been lately discovered; and plumbago or black lead has been observed near the baths of Binay. This principality contains a great number of cities, towns and villages, so that the whole country has been denominated a large city. Its capital is Turin, which is an archiepiscopal see; besides which there are eight bishoprics. The principal rivers are the Po, the Tanaro, the Sturia, and the Doria. The chief exports consist of silk, which are chiefly manufactured at Lyons, some hemp, and large herds of cattle. In the year 1802, the whole country was annexed to the French republic, and divided into six departments, under the names of the Po, Doria, Marengo, Sezia, Stura, and Tanaro.

PIEDOUCHE, *French*, formed from the Italian *peduccio*, *foot*, in *Architecture*, a little stand, or pedestal, either oblong or square enriched with mouldings, serving to support a bust, or other little figure. This is called a bracket pedestal.

PIEDRA DE LA HYADA, in *Natural History*, the name given by the Spaniards to a stone found in many parts of America, particularly in New Spain; and famous among the Indians for curing the colic on being applied to the navel. It is green, and is a species of jasper, approaching to the nature of the lapis nephriticus, and is called by many *colicus lapis*, from its virtues.

PIEDRAHILA, in *Geography*, a town of Spain, in the province of Leon; 26 miles W.N.W. of Avila.

PIEDRAS, a river of Terra Firma, which runs into the Caribbean sea, 40 miles E. of Cape Aguja.

PIEDROIT, in *Architecture*, a pier, or a square kind of pillar, part of which is hid within a wall.

The only thing in which it differs from a pilaster is, that the latter has a regular base and capital, which the other wants. See PILASTER.

PIEDROIT is also used for a part of the solid wall annexed to a door or window; comprehending the door-post, chambranle, tableau, leaf, &c.

PIEGAIO, in *Geography*, a town of Italy; 14 miles S.W. of Perugia.

PIELAWESI, a town of Sweden, in the government of Kuopio, seated on a lake; 35 miles N.W. of Kuopio.

PIELIS, a town of Sweden, in the government of Kuopio, on a large lake; 70 miles E.N.E. of Kuopio.

PIEMONTE, a town of Istria; 21 miles S. of Capo d'Istria.

PIENES, a small island of Japan, near the harbour of Sacca.

PIENIN, a town of Poland, in the palatinate of Cracow; 36 miles N. of Cracow.

PIENO, a town of Italy, in the department of the Montagna; 18 miles N. of Lecco.

PIENO, Ital. *Full*, in *Music*. Sometimes it implies energy or force. See **RIPIENO**.

PIENZA, in *Geography*, a town of Etruria, and the see of a bishop; 45 miles S. of Florence. N. lat. 43° 3'. E. long. 11° 34'.

PIE-POUDER COURT. See **COURT**.

PIER, in *Building*, derived from the French *pierre*, a stone, denotes a mass of stone, &c. opposed, by way of fortrefs, against the force of the sea, or a great river, for the security of ships that lie at harbour in any haven, such are the pier of Dover, described by Camden Brit. &c., the

pier of Ramsgate, and the haven pier of Great Yarmouth, mentioned 22 Car. II.

PIERS are also used in *Architecture* for a kind of pilasters, or buttresses, raised for support, strength, and sometimes for ornament.

PIERS, *Circular*, are called *massive columns*, and they are with or without caps, and are frequently seen in Saracenic architecture.

PIERS of a Bridge. See **BRIDGE**.

M. Belidor observes that, when the height of the piers is about six feet, and the arches are circular, it is sufficient to make their thickness the sixth part of the width of the arch, and two feet more; but when the arches become of a great span, the thickness of the piers may be reduced to the sixth part; but then the depression of the two feet doth not take place at once; that is, in an arch of above forty-eight feet, three inches are taken off for every six feet of increase of the width of the arch. The thickness of the piers supporting elliptic arches is greater than in the former proportion: thus, in an arch of seventy-five feet wide, the thickness of the pier, whose height is about six feet, should be 13.5 when the arch is circular, and fifteen feet when it is elliptical.

The same author makes the abutments one-sixth part more than the piers of the largest arch.

Mr. Muller has calculated the following table, containing the thickness of the piers of bridges.

TABLE containing the Thickness of the Piers of Bridges.

	6	9	12	15	18	21	24
20	4.574	4.918	5.165	5.350	5.492	5.610	5.698
25	5.490	5.913	6.216	6.445	6.645	6.801	7.930
30	6.386	6.816	7.225	7.513	7.746	7.939	8.102
35	7.258	7.786	8.200	8.532	8.807	9.037	9.233
40	8.404	8.691	9.148	9.523	9.835	10.101	10.328
45	8.965	9.579	10.077	10.489	10.837	11.136	11.394
50	9.805	10.454	10.987	11.435	11.817	12.146	12.434
55	10.640	11.245	11.882	12.364	13.019	13.149	13.218
60	11.400	12.110	12.718	13.281	13.723	14.109	14.314
65	12.265	13.025	13.648	14.185	14.654	15.082	15.433
70	13.114	13.869	14.517	14.049	15.573	16.011	16.400
75	14.000	14.705	15.336	15.965	16.480	16.940	17.354
80	14.747	15.542	16.234	16.842	17.381	17.864	18.298
85	15.513	16.328	17.041	17.674	18.237	18.742	19.194
90	16.373	17.102	17.929	18.578	19.157	19.679	20.152
95	17.184	17.826	18.772	19.438	20.036	20.577	21.068
100	17.991	18.848	19.610	20.293	20.908	21.466	21.976

The first horizontal line expresses the height of the piers in feet, from 6 to 24 feet, each increasing by 3: the first vertical column, the width of arches from 20 to 100 feet, for every 5 feet.

The other columns express the thickness of piers in feet and decimals, according to the respective height at the head of the column, and the width of the arch against it in the first column.

Rectangular piers are seldom used but in bridges over small rivers; in all others they project from the bridge by a triangular prism, which presents an edge to the stream, in order to divide the water more easily, to prevent the ice from sheltering there, as well as vessels from running foul against them. This edge is terminated by the adjacent surfaces at right angles to each other at Westminster bridge; but those of the Pont-royal, at Paris, make an acute angle of about 60°. However the French, in their later constructions, make this angle to terminate by two cylindrical surfaces, whose bases are arcs of 60 degrees. Muller's *Pract. Fortif.* part iv. sect. 1. p. 257, &c.

PIER Head, in *Geography*, a cape on the north-east coast of New Holland, and west point of Thirsty sound.

PIERA, a town of Spain, in Catalonia; 16 miles N.W. of Barcelona.

PIERACO, a town of the marquisate of Ancona; 5 miles N. of Ancona.

PIERAGE, money paid for the use of a pier.

PIERBACH, in *Geography*, a town of Austria; 8 miles N.N.W. of Grein.

PIERCE'S ISLAND, a small island in Piscataqua river.

PIERCEA, in *Botany*, a name of Miller's, most unfortunately constructed, though well intended, to honour the late duke of Northumberland; so that it ought to have been *Percya* or *Percæa*. That great patron of Botany, and distinguished cultivator, to whom the science is so much indebted, has certainly long merited such a compliment, in preference to a cloud of names, in every respect far inferior; but Miller's supposed genus is not in any respect different from *RIVINA*. See that article.

PIERCED, **PERCE'**, in *Heraldry*, is when an ordinary is perforated, or struck through; shewing, as it were, a hole in it.

This piercing is said to be expressed in blazon as to its shape: thus if a cross have a square hole, or perforation in the centre, it is blazoned, *square-pierced*, which is more proper than *quarter-pierced*, as Leigh expresses it; and accordingly the French call it *percé en quarré*. When the hole or perforation is round, it must be expressed *round-pierced*; which Gibbon in Latin calls *perforata*; because all holes made with pierces, or augers, are round. If the hole in the centre be in the shape of a lozenge, it is expressed *pierced lozenge-ways*.

All piercings must be of the colour of the field, because piercing implies the shewing of what is under the ordinary, or bearing. And when such figures appear on the centre of a cross, &c. of another colour, the cross is not to be supposed pierced, but that the figure on it is a charge, and must be accordingly blazoned.

PIERCED Island, in *Geography*, a small island or rock, in the gulf of St. Lawrence, pierced with two natural arches, through which the sea passes; 15 miles S. of Cape Gaspe.

PIERCING, among *Farriers*. To pierce a horse's shoe lean, is to pierce it too near the edge of the iron. To pierce it fut, is to pierce it farther in.

PIERCY, in *Geography*, a town of America, in N. Hampshire, and county of Coos, containing 211 inhabitants.

PIERCY Island, a small island near the east coast of New Zealand; east of Cape Brett.

PIERIA, in *Ancient Geography*, a country of Syria, in the Seleucid territory. This country derived its name from mount Pierius or Pieria, which the Macedonians so called after mount Pierius in their own country. It was the most southern country, and touched on Thessaly, from which it was separated by mountains.—Also, a town of Macedonia.—Also, a mountain of Syria, which, according to Strabo, extended from the south to the north, and joined with mount Amanus. This mountain took its name from that of Greece.—Also, a town of Greece, in Bœotia, afterwards called Lyncos.

PIERIDES, among the *Ancients*, an epithet given to the Muses, upon account of their having been born in that part of the country of Macedon which was called *Pieria*.

PIERIUS MOUNTS, in *Ancient Geography*, a mountain of Asia, in Syria, on the coast of the Mediterranean sea, between the gulf Issicus to the north and the mouth of the river Orontes; about lat. 36° 15'.

PIERMONT, in *Geography*, a town of America, in the state of N. Hampshire, and county of Grafton, containing 877 inhabitants.

PIEROUGAMIS, a tribe of Indians in Canada, who inhabit the west bank of the lake of St. John.

PIERRE, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Louhans; 15 miles N. of Louhans. The place contains 1510, and the canton 12,408 inhabitants, upon a territory of 255 kilometres, in 18 communes.

PIERRE Buffiere, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Limoges; 9 miles S.S.E. of Limoges. The place contains 813, and the canton 8093 inhabitants, on a territory of 217½ kilometres, in 10 communes.

PIERRE a l'Oisseau, a small island in the English channel, near the coast of France. N. lat. 48° 54'. W. long. 3° 24'.

PIERRE Pertuis, a pass in mount Jura, cut out of a rock; 8 miles N.W. of Bienne.

PIERRE d'Albigny, St., a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of Chambéry. The place contains 2714, and the canton 6943 inhabitants, on a territory of 70 kilometres, in 6 communes.

PIERRE-Eglise, St., a town of France, in the department of the Channel, and chief place of a canton, in the district of Valognes. The place contains 1619, and the canton 13,342 inhabitants, on a territory of 170 kilometres, in 20 communes.

PIERRE d'Oleron, St., a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Marennnes. The place contains 4249, and the canton 9653 inhabitants, on a territory of 135 kilometres, in 3 communes.

PIERRE-Lette, a town of France, in the department of the Drome, and chief place of a canton, in the district of Montelimart. The place contains 2536, and the canton 12,534 inhabitants, on a territory of 327½ kilometres, in 14 communes.

PIERRE-le-Moutier, St., a town of France, in the department of the Nièvre, and chief place of a canton, in the district of Nevers. The place contains 1969, and the canton 8615 inhabitants, on a territory of 310 kilometres, in 10 communes.

PIERRE sur Dives, St., a town of France, in the department of the Calvados, and chief place of a canton, in the district of Lisieux. The place contains 1499, and the canton 9287 inhabitants, on a territory of 145 kilometres, in 28 communes.

PIERRE d'Automne, a French name translated from the Chinese.

Chinefe. It is the name of a medicinal ſtone, famous throughout the Eaſt for curing all diſorders of the lungs. Many people ſuppoſe it had its name of the *autumn-ſtone*, from its being only to be made at that ſeaſon of the year; but it may be made equally at all times, and the origin of the name is to be farther ſearched into.

The Chineſe chemiſts, like thoſe of all other nations, delight in a fort of gibberiſh. A part of this is, the referring the ſeveral parts of the body to the ſeveral ſeaſons of the year. The lungs are in this ſcheme referred to autumn. This appears in their writings; and thus the ſtone for diſeaſes of the lungs came to be called *autumn-ſtone*.

It is a tedious preparation of human urine, and made as follows: they put thirty pints of the urine of a ſtrong and healthy young man into a large iron pot, and ſet it over a gentle fire; and when it begins to boil, they add to it, drop by drop, about a large tea-cup full of rape-oil; it is then left on the fire till the whole is evaporated to a thick ſubſtance reſembling black mud; they then take it out of the pot, and laying it on a flat iron, they dry it ſo that it may be powdered very fine.

This powder they moiſten with freſh oil, and put the maſs into a double crucible, ſurrounded with coals, where it ſtands till thoroughly dried again. They finally powder this again, and putting it into a china-veſſel, covered with ſilk cloth and a double paper, they pour on boiling water, which makes its way, drop by drop, through theſe coverings, till ſo much is got in as is ſufficient to reduce it to a paſte. This paſte is well mixed together in the veſſel it is kept in, and this is put into a veſſel of water, and the whole ſet over the fire. The matter thus becomes again dried in *balneo Mariæ*, and is then finiſhed. *Obſerv. fur les Coût. de PAſie*, p. 258.

PIERRE de Cayenne, in *Ornithology*. See *PHASIANUS Pauxi*.

PIERREFITTE, in *Geography*, a town of France, in the department of the Meufe, and chief place of a canton, in the diſtrict of Commercy; 7 miles W. of St. Michael. The place contains 660, and the canton 9249 inhabitants, on a territory of $357\frac{1}{2}$ kilometres, in 27 communes.

PIERREFONTAINE, a town of France, in the department of the Doubs, and chief place of a canton, in the diſtrict of Baume. The place contains 1110, and the canton 7889 inhabitants, on a territory of $272\frac{1}{2}$ kilometres, in 21 communes.

PIERREFORT, a town of France, in the department of the Cantal, and chief place of a canton, in the diſtrict of St. Flour. The place contains 1266, and the canton 8905 inhabitants, on a territory of $287\frac{1}{2}$ kilometres, in 11 communes.

PIERRES SONORES, ſtones that have a metalline found, of which muſical inſtruments of percussion are made in China. See *CHINESE Muſic*.

PIERREVILLE, St., in *Geography*, a town of France, in the department of the Ardèche, and chief place of a canton, in the diſtrict of Privas. The place contains 1471, and the canton 7856 inhabitants, on a territory of $147\frac{1}{2}$ kilometres, in 7 communes.

PIERSZAIÉ, a town of Lithuania, in the palatinate of Wilna; 60 miles E. of Lida.

PIERUS, or *PEIRUS*, in *Ancient Geography*, a river of the Peloponneſus, in Achaia Propria, which traversed the territory of the town Phææ. Strabo ſays that it diſcharged itſelf into the Achelous.—Alſo, a lake of Theſſaly.—Alſo, a mountain of Macedonia. It is ſaid that a perſon, named Pierus, eſtabliſhed on this mountain the worſhip of the Muſes, whence they were denominated “*Pierides*.”

PIES, in our *Ancient Law-Books*. *Freres Pies* were a

fort of monks, ſo called becauſe they wore black and white garments, like magpies; the ſame, we ſuppoſe, with thoſe ſince called Carmelites, who, for a like reaſon, were anciently called by the French *Freres Barrez*.

They are mentioned by Wallingham, p. 124. “*In quodam veteri cœmeterio, quod fuerat quondam fratrum, quos Freres Pies veteres appellabant.*”

PIESKE, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 40 miles W.S.W. of Novogrodek.

PIESMA, a word uſed by the ancients to expreſs the remaining maſs, after the expreſſion of any fluid ſubſtance from among its moſt ſolid parts. Thus the cake remaining in the bag, after the expreſſion of oils, is called by this name; but there are inſtances of authors calling the expreſſed juice, inſtead of the reſiduum, by this name. Thus Dioſcorides calls the expreſſed juice of the bay-berries, the *pieſma laurinum*; and others, the expreſſed juice of roſes, *pieſma roſarum*, paying no regard to the roſe-cake left behind.

PIESTER, the name uſed by the ancients for the preſs which they employed in preparing the ſeveral juices of plants, &c.: hence the word *pieſma*; which ſee.

PIESTRON, a word uſed by Hippocrates to expreſs a fort of forceps, which he recommends to be uſed in difficult labours, to break the bones of the cranium of the fœtus, when its head is too large to paſs whole. It was alſo called *embryſtlaſtes*.

PIETANTIA, or *PITTANCE*, a portion of victuals diſtributed to the members of a college, or other community, upon ſome great feſtivals.

PIETANTIARIUS. See *PITANCIARIUS*.

PIETERMAN, in *Ichthyology*, the name uſed by ſome for a fiſh of the cuculus kind, approaching to the nature of the *draco marinus*, or weaver; and more uſually called among authors by its Braſilian name, *niqui*.

PIETISTS, in *Eccleſiaſtical Hiſtory*, a religious ſect that ſprung up towards the cloſe of the 17th century, among the Proteſtants of Germany; ſeeming to be a kind of mean between the Quakers of England, and the Quietiſts of the Romiſh church.

This ſect originated in the zeal of certain perſons, who, with the beſt intentions, endeavoured to ſtem the torrent of vice and corruption, and to reform the licentious manners both of the clergy and of the people. However, many, deluded by the ſuggeſtions of an irregular imagination, and an ill-informed underſtanding, or guided by principles and views of a more criminal nature, ſpread abroad new and ſingular opinions, falſe viſions, unintelligible maxims, auſtere precepts, and imprudent clamours againſt the diſcipline of the church: all which excited the moſt dreadful tumults, and kindled the flames of contention and diſcord.

The learned Spener was at the head of the firſt reformers, who, by the private ſocieties he formed at Frankfort, with a deſign to promote vital religion, roused the luke-warm from their indifference, and excited a ſpirit of vigour and reſolution in thoſe who had been ſatisfied to lament in ſilence the progreſs of impiety. With this view he publiſhed a book, entitled “*Pious Deſires*,” in which he repreſented in an affecting manner the diſorders of the church, and propoſed the remedies that were proper to heal them. The religious meetings above-mentioned, or colleges of piety as they were called, however well deſigned in their original eſtabliſhment, tended in many places to kindle in the breasts of the multitude the flames of a blind and intemperate zeal, whoſe effects were impetuous and violent;

violent;

violent : so that these institutions of pietism became objects of reproach and occasions of complaint.

The tumult this produced was farther promoted by the commotions that arose at Leipzig in the year 1689, when certain pious and learned professors of philosophy undertook to explain the scriptures in their colleges, with a view of forming candidates for the ministry into a more accurate acquaintance with these sources of religious knowledge. The novelty of this method of instruction excited attention, and the lectures that were delivered to this purpose were much frequented. Suspicions and rumours of an unfavourable kind were soon industriously propagated, and the professors were prohibited from pursuing the plan of religious instruction which they had undertaken. During these troubles and divisions, the invidious denomination of Pietists was first invented; or at least before this period it was not commonly known. It was originally applied by some inconsiderate persons to those who frequented the biblical colleges, and lived in a manner suitable to the instructions and exhortations that were there addressed to them; and afterwards it was used to characterise all who were distinguished by the excessive austerity of their manners, or who, regardless of truth and opinion, were only intent upon practice, and turned the whole vigour of their efforts towards the attainment of religious feelings and habits. At this time the denomination was also sometimes applied to persons whose motley characters exhibited an enormous mixture of profligacy and enthusiasm, and who better deserved the title of delirious fanatics. The contest, thus begun, very soon spread through all the Lutheran churches in the different states and kingdoms of Europe. Many persons of various ranks and professions, of both sexes, learned and illiterate, pretended a divine impulse for pulling up iniquity by the root, and restoring to its primitive lustre the declining cause of piety and virtue, and for establishing a better discipline in the Christian church. Assemblies, similar to those established by Spener, were introduced for this purpose into Leipzig and other places: but they were not all conducted with prudence and order. Into these assemblies there were introduced several extravagant and hot-headed fanatics, who foretold the destruction of Babel, *i. e.* the Lutheran church; who terrified the populace with fictitious visions, assumed the authority of prophets honoured with a divine commission, revived doctrines that had long before been exploded and condemned, declared the approach of the millennium, and were guilty of many outrages against order and peace. The governors of the church and of the state were alarmed at the progress of the divisions which these enthusiasts produced, and many severe laws were enacted against the Pietists. These revivers of piety were of two kinds: one sect, at the head of which was Spener, proposed to carry on their plan without introducing any change into the doctrine, discipline, or form of government in the Lutheran church: the other party were for introducing considerable alterations both in doctrine and ecclesiastical polity. Many mistakes have been occasioned by confounding these two parties; the former of which were zealously intent upon a very important object, the revival of piety, and, with this view, the reformation of public seminaries, where ministers were educated, both as to the mode of instruction and the extent of discipline: but the latter were, for the most part, totally destitute of reason and judgment; their errors were the reveries of a disordered brain; and they were rather to be considered as lunatics than as heretics. Some among them were less extravagant, and tempered the singular notions they had derived from reading or meditation, with

a certain mixture of the important truths and doctrines of religion. They were mostly, however, of the mystic kind. For a more particular account we must refer to Mosheim's *Ecll. Hist.* vol. iv. 8vo.

Many gross errors are charged on the Pietists, in a book intitled "Manipulus Observationum Antipietisticarum;" but they have too much the severity of polemical exaggeration; at least it is certainly so with regard to a great part of them.

In effect, there are Pietists of several kinds: some run into gross illusions, and carry their errors to the overturning a great part of the Christian doctrine; others are only visionaries; and others very honest and good people, who, disgusted with the coldness and formality of other churches, and charmed with the fervent piety of the Pietists, are attached to their party, without giving in to the grossest of their errors.

PIETISTS, otherwise called the "Brethren and Sisters of the Pious and Christian Schools," a society formed in the year 1678, by Nicholas Barre, and obliged, by their engagements, to devote themselves to the education of poor children of both sexes.

PIETOSA, in the *Italian Music*, signifies to play or sing in a soft manner, fit to move pity or compassion.

PIETRA CASTELLO, in *Geography*, a town of Naples, in Capitanata; 6 miles N.W. of Volturara.—*P. Corbara*, a town of Corsica; 11 miles N. of Bastia.—*P. Galla*, a town of Naples, in Basilicata; 2 miles S.S.W. of Accerenza.—*P. Mala*, a town of Naples, in Calabria Citra; 11 miles S. of Cosenza.—*P. Malera*, a town of Naples, in Lavora; 7 miles N. of Capua.—*P. Maura*, a town of Naples, in Capitanata; 4 miles N.W. of Lefina.—*P. Paula*, a town of Naples, in Calabria Citra; 4 miles W.N.W. of Cariati Vecchia.—*P. Pertosa*, a town of Naples, in Basilicata; 12 miles S.E. of Potenza.—*P. Prezia*, a town of Sicily, in the valley of Noto; 10 miles S.W. of Castro Giovanni.—*P. Pugno*, a town of Corsica, in the department of Corté.—*P. Pulcina*, a town of Naples, in Principato Ultra; 3 miles N. of Benevento.—*P. Pulema*, a town of Naples, in Principato Ultra; 9 miles N.N.E. of Benevento.—*P. di Roma*, a town of Sicily, in the valley of Demona, on the N. coast; 18 miles W. of Pati.—*P. Sama*, a town of the republic of Lucca; 12 miles W. of Lucca.—*P. Santa*, a town of Etruria; 6 miles S.E. of Messa.—*P. Vairan*, a town of Naples, in Lavora; 11 miles E. of Sezza.

PIETRA Mala, a mountain that rises in the middle of the Apennines on the road to Bologna, about 40 miles from Florence. This mountain is rendered remarkable by a flame that spreads over a small part of its surface, and burns almost continually without producing any of those destructive effects which accompany volcanic explosions.—A similar phenomenon is observed on the side of a mountain about four miles from Cavigliano: here the flame, which shews itself low down on the declivity of the mountain, covers a space of about 140 feet; and it runs along in crevices, and burns much stronger in some places than in others. Its colour is either bright yellow, or blue, like spirits of wine, and it rises little more than half a foot from the surface; but in rainy weather, and particularly in winter, it is said to increase considerably, and mount to the height of six or seven feet. It was extinguished in some places by waving hats strongly over it, and reproduced by firing a pistol into a small train of gunpowder, and sometimes by merely throwing a lighted paper upon the spot where it had disappeared. It emits a strong odour, resembling that of ether. Naturalists are divided in their opinions

as to the cause of this phenomenon: some suppose it to be electric, others phosphoric, and others again volcanic. In favour of this latter opinion, it is alleged that there are vestiges of ancient eruptions in the neighbourhood; that shocks of earthquakes frequently agitate the surrounding mountains; and that sulphureous bubbles are perceivable in the vicinity, which are so inflammable as to take fire at the approach of a torch, &c. But on the other hand, it is said, that if the flames of Pietra Mala proceeded from any such cause, the ground over which they hover must be heated, and its heat increase if opened, because it would be nearer the subterranean furnace. On the contrary, the flame in this mountain communicates but little heat when burning, and when extinguished leaves the ground cold, and without the usual vestiges of fire. Hence others have been led to ascribe it to a sort of oily substance or petroleum, with which they suppose the adjacent earth to be impregnated. But if this were the cause, it is said, that the flames, instead of being increased, would be diminished or extinguished by the rains and tempests of winter, and the crevices which emit the flame must exhibit some traces of this oily vapour; but the flame glows with the greatest vivacity in winter, and the soil manifests no appearance of any oily or bituminous substance. The first of these facts is equally decisive against the operation of the electric fluid and phosphoric exhalations. Whatever be its cause, the flame illuminates the whole tract around it, and banishes the horror of night from one of the most dreary solitudes of the Apennines. Similar phenomena were observed in or near the same region anciently, as Pliny the elder (lib. xi. cap. 3.) notices the appearances of flames in the territory of Mutina, which includes the neighbouring Apennines.

PIETRA *Embofcata*, in *Natural History*, a name given by the Italians to the Florentine marble, so remarkable for its delineations.

This marble is found in thin strata, and is full of cracks: in these cracks there is usually found a black mineral matter, which, getting into the substance of the stone a little way on each side of the crack, forms there various delineations, or the figures of pieces of moss, bushes, and the like: the paler pieces of the marble usually have these delineations; the darker coloured having the forms of trees and houses, or the ruins of old buildings.

PIETRAFEZA, in *Geography*, a town of Naples, in Basilicata; 7 miles S.W. of Potenza.

PIETRAGRUA, CARLO LUIGI, of Florence, in *Biography*, a master of considerable reputation in his day, composed two operas for Venice; "Il Pastor Fido," in 1721; and "Romolo e Tazio," in 1722. Professors speak of Pietragrua in such terms as remove all doubt of his merit.

PIETRALBO, or PETRALBO, in *Geography*, a town of the island of Corsica; 10 miles S. of St. Florenzo.

PIETY, *Mounts of*. See MOUNT.

PIEVE, in *Geography*, a town of Genoa; 2 miles N.W. of Albenga.

PIEVE, *La*, a town of Italy, in the department of the Lower Po, on the Reno, surrounded with an earthen rampart and a ditch.

PIEVE *del Duca*, a town of Italy, in the department of the Rubicon; 4 miles W. of Rimini.

PIEVE *del Mona*, a town of Italy, in the department of the Upper Po; 5 miles E.N.E. of Cremona.

PIEVE *St. Giacomo*, a town of Italy, in the department of the Upper Po; 7 miles E. of Cremona.

PIEVE *a Sieve*, a town of Etruria; 10 miles E. of Florence.

PIEVE *di Cadora*. See CADORA.

PIEVE *di Sacco*, a town of Italy, in the Paduan, on a canal called Fiumcello, containing 5100 inhabitants; 10 miles E. of Padua.

PIEVE *de St. Maurizio*, a town of Italy, in the department of the Upper Po; 12 miles E. of Cremona.

PIEVE *St. Stefano*, a town of Etruria, on the Tiber; 15 miles N. of Arezzo.

PIEUX, LES, a town of France, in the department of the Channel, and chief place of a canton, in the district of Valognes; 12 miles W. of Valognes. The place contains 1398, and the canton 10,420 inhabitants, on a territory of 170 kilometres, in 15 communes.

PIEXE-GALLO, in *Ichthyology*, a name given by the Portuguese to a fish caught about the shores of the Brasils, and much resembling our *doree* or *faber piscis*; more usually known among authors by its Brazilian name, *abacatuia*.

PIEXE-*Porco*, a name by which some authors have called the *monoceros*, or unicorn-fish of Clusius. The name is Portuguese, and signifies hog-fish, this little creature having a mouth like a hog.

PIEXMAHL, in *Geography*, a town of Sweden, in the government of Kuopio; 39 miles S.S.W. of Kuopio.

PIFENDEL, in *Biography*, an eminent performer on the violin, in the service of Augustus II., king of Poland. According to Quantz, Pifendel had in his youth received instructions in singing from Pistocchi, and on the violin from Tofelli. Quantz is very warm in his praises, calling him a profound theorist, a great performer, and a truly honest man. It was from this worthy concert-master, says he, that I learnt to play an adagio, and to compose in many parts.

Pifendel had in his youth travelled through France and Italy, where he had acquired the peculiarities in the taste of both countries, and so blended them together as to form a third genus, a mixed style of writing and playing, which was half French and half Italian. Influenced by his example, Quantz declares that he always preferred this compound style to that of Italy, France, or the national style of his own country.

PIFFERO, Ital. a flute, fife, or flageolet.

PIG, a small animal of the hog or swine kind. See HOG, and SWINE.

PIG, *Guinea*. See CAVIA *Cobaya*.

PIG-Nut, or *Earth-nut*, in *Botany*. See BUNIAM.

PIG-Nut. See WALNUT-Tree.

PIG-Cafe, in *Agriculture*, a sort of narrow case or stall, in which an animal of this kind is confined while it is undergoing the process of fattening, so as not to be able to turn itself completely round, by which it is supposed to fatten better and more expeditiously, as well as with a less quantity of food in proportion to that which is used for equal sized animals fed in other methods.

These cases are constructed in separate divisions, in such a manner, that each of them may contain a pig, and fit him as nearly as possible when he is in it; but he must not be able to turn himself round; there is, however, a space left at the bottom of each of them, by which he is enabled to lie down at pleasure, in which case his feet pass through the space left. Upon one side of such buildings there is usually a range of small troughs in the walls or boardings, and on the other a row of sliders, which shut the pigs in. The paving in the bottoms of these divisions slopes gently backwards to prevent wetness, and no litter is ever employed in them, but they are kept clean and sweet by the use of a hoe and broom.

Pig-cases of this sort are sometimes raised from foundations laid in the ground, and at others erected upon wheels in

in a kind of wooden building, so as to move about on grass-land. They are frequently met with in the neighbourhood of Maldon in Essex, and will be more fully noticed in speaking of swine. See SWINE.

PIG-Stie, in *Rural Economy*, the name of the place where hogs are kept. Buildings of this kind should always be large and commodious. See HOG-Stie.

PIG-Tail, in *Agriculture*, a provincial term sometimes applied to a small strip of ground generally in the state of grass.

PIG of Lead, the eighth part of a fother; amounting to about 250lb. weight.

PIG Creek, in *Geography*, a river of Virginia, which runs into the Staunton, N. lat. 36° 52'. W. long. 79° 42'.

PIG Iron, in the *Iron Works*. Those masses of iron which result from the first process of extracting from the ore, are called *pigs*, and in this state it is called *pig iron*. It is principally used to distinguish it from bar iron, which is malleable, and nearly pure iron. Pig iron is of various qualities, according to the quantity of carbon it contains. The highest carburet is called N° 1, the next N° 2, and so on. That containing the lowest dose of carbon, which is known by its white fracture, and greater hardness, is called *forge pig*, because it has been thought the most fitted for making malleable iron. See the article IRON.

PIGALLE, JOHN BAPTIST, in *Biography*, an eminent French sculptor, was born at Paris in 1714. He was the son of a carpenter employed about the royal buildings, and shewed an early fondness for modelling, which at length gave him a desire for excelling in the art of sculpture. He spent three years at Rome in copying after the antique, and on his return stopt at Lyons, where he met with employment which occupied him a year and a half. Here he finished his model of the statue of Mercury, which he brought with him to Paris, where it was greatly admired. It was some time before he met with encouragement; but at length he excited the attention of the minister, and of Mad. Pompadour, who obtained for him many commissions. He was admitted into the academy of painting and sculpture in 1744, and having executed his Mercury in marble, he made a Venus for its companion, which was equally the subject of praise. Both these statues were presented by the king to Frederic of Prussia. Pigalle was employed, in 1756, to execute a mausoleum for marshal Saxe, which was said to be the grandest composition in sculpture that exists. This caused him to be employed for the monument erected in 1765, by the city of Rheims, to the glory of Lewis XV. In 1780 he was employed on a grand monument for the count d'Harcourt. His concluding piece was the figure of a young girl taking a thorn out of her foot, which was greatly admired for its beauty and delicacy. He died in 1785, being then rector and chancellor of the academy. As an artist he was entirely indebted to study and application: his skill was rather talent than genius, and his ideas were rather just than extensive.

PIGAYA, in *Natural History*. See PYGAYA.

PIGEON, in *Ornithology*. See COLUMBA.

PIGEON, in *Rural Economy*, a well-known domestic bird. There are only two distinct sorts of pigeons, the wild and the tame; and the tame rough-footed ones differ not much from the wild, only they are somewhat bigger, and more familiar: the wild usually perch upon trees, being more seldom seen on the ground. They are such as breed in woods, sea-rocks, &c. and the tame such as are bred in dove-houses.

But the varieties in the tame sort are numerous, and distinguished by a variety of different names, as carriers, croppers, powters, horsemen, runts, jacobins, turbits, helmets,

nuns, tumblers, barbs, petits, owls, spots, trumpeters, shakers, turners, finikins, &c. from which, when differently paired, are bred bastard pigeons, such as are called from the cropper or powder, and the carrier, powting horsemen; from the tumbler and the horsemen, dragoons. These, however, deserve little attention, being only kept for fancy, and not profit, though the same method is used in breeding them.

And there are different sorts of runts, one called Spanish runt; generally of a blood-red or mottled colour: they are very loose feathered, and large bodied, but breed not so often as the smaller sorts.

The horsemen are excellent breeders, and are not easily took; the common English runt is also a good sized pigeon, and breeds well.

Also the pigeon called the Leghorn is a sort of runt, only distinguished by a little wattle over his nostril: he is a full bodied pigeon, whose feathers lie close to the body, and is an excellent breeder, and generally of a grizzled colour, ermined round the neck.

It may be noticed that those who keep pigeons for the purpose of breeding, should have bastard bred pigeons, such as powting horsemen, powting dragoons, from a powder or cropper, and a Leghorn; as such pigeons will breed nine or ten pair of young ones in the year; and when they have young ones they feed them well.

But of those kinds which are bred in pigeon-houses, the grey pigeon, inclining to ash colour and black, is the best; and generally shews fruitfulness by the redness of the eyes and feet, and by the ring of gold colour which is about the neck.

In respect to the time of stocking there are two seasons in the year at which the pigeon-house may be supplied: the first is May; for the pigeons having much strengthened themselves during the winter, are in a condition soon to yield profit to the buyer. Secondly, in August, when there are a great number of young pigeons that have been well fed with corn, from the harvest in that season. In general pigeons will live about eight years, but they are only prolific for the first four years; afterwards they are worth nothing, for when they are once past that age all they do is, to prevent the profit that might be reaped by others that are younger. It is something difficult to know how to distinguish their age, and requires experience.

And the runts may be distinguished again into greater or smaller: those which are called the Spanish runts are much esteemed, being the largest sort of pigeon, but are sluggish and more slow of flight than the smaller sorts of runts: but the smaller runts are better breeders, and quicker of flight, for which they are esteemed. As for the colours of their feathers, they are uncertain, so that a judgment cannot be made of the sort by them.

The next sort which makes the largest figure, but is not, in reality, the largest bird, is the cropper, so called, because they usually, by attracting the air, blow up their crops to an extraordinary bigness, even so as to be sometimes as large as their bodies. This sort is the most valued, according as it can swell up its crop. The bodies of this sort are about the bigness of the smaller runts, but are somewhat more slender: this sort also is of various colours in the feathers.

The shakers are of two sorts, *viz.* the broad-tailed shaker, and the narrow-tailed shaker: these are so called, because they are almost constantly wagging their heads and necks up and down; the broad are distinguished from the narrow, in that the broad-tailed sort abounds with tail-feathers about twenty-six in number; but the narrow-tail

PIGEON.

shakers have not so many. These, when they walk, carry their tail-feathers and crest spread abroad like a turkey-cock: they have likewise a diversity of feathers.

The jacobins, or cappers, are so called on account of certain feathers which turn up about the back part of the head: some of this sort are rough-footed; they are short billed, the iris of their eye of a pearl colour, and the head is commonly white.

The turbit, which some suppose to be a corruption of the word corbeck, or curtbeke, as they are called by the Dutch, which seems to be derived from the French, courtbeck, and signifies a short bill, for which this pigeon is remarkable; has the head flat, and the feathers on the breast spread both ways; these are much of the same size with the jacobines.

The carriers are those pigeons which are said to have been employed sometimes in carrying letters, &c. They are about the size of common pigeons, and of a dark blue or blackish colour, which is one way of distinguishing them from other sorts: they are also remarkable for having their eyes compassed about with a broad circle of naked spongy skin, and for having the upper chap of their beak covered more than half from the head, with a double crust of the like naked fungous body. The bill, or beak, is moderately long, and black.

The barb, or Barbary pigeon, is another sort, whose bill is like that of the turbit, short, and thick, having a broad and naked circle of a spongy white substance round about the eye, like that of the carrier pigeon; the iris of the eye is white, if the feathers of the pinion are inclinable to a darker colour, but if red they are white, as it is observed in other birds.

The limiters are supposed to be the same the Dutch call dragons: these shake their wings as they fly, and rise commonly in a circular manner in their flight, the males, for the most part, rising higher than the females, and frequently falling and flapping with their wings, which makes a great noise that may be heard a great way off, which often is the cause of their breaking or shattering their quill-feathers. These very much resemble the tumbler pigeon; the difference chiefly is, that the tumbler is somewhat smaller, and in its flight will tumble itself backward over its head; the diversity of colours in the feathers makes no difference.

The helmet pigeon is distinguished from the others, because it has the head, the quill-feathers, and the tail-feathers, always of one colour, sometimes black, sometimes white, or red, or blue, or yellow, but the other feathers of the body are of a different colour.

The light horseman; this is supposed to be a cross between a cock cropper and a hen of the carrier breed: because they seem to partake of both, as appears from the excrescence of flesh upon their bills and the swellings of their crops: these are not inclined to leave the place of their birth, or the house that they have been used to.

The bastard-bill pigeon is something bigger than the Barbary pigeon; they have short bills, and are generally said to have red eyes, though probably those coloured eyes belong only to those that have white feathers.

There is a pigeon called the turner, which is said to have a tuft of feathers hanging backwards on the head which parts like a horse's mane.

There is also a pigeon of the smaller sort, called the finikin, but in other respects like the former.

There is another pigeon called the spot, supposed to take its name from a spot on the forehead, just above the bill; and the feather of its tail is always of the same colour with the spots, and all the other feathers are white.

The Mahomet, or mawmet pigeon, supposed to be brought from Turkey, is singular for its large black eyes, but the other parts are like those of the Barbary pigeon.

It is necessary to observe that great care must be taken to make convenient places to breed in; each pair of pigeons must have two nests, those with baskets in them are best, as before one pair can go out of the nest, or feed themselves, the old ones will be sitting again. When the young ones are taken, clean out the nest, or put in a clean basket, for cleanliness is a circumstance of great consequence to the raising of pigeons.

Many suppose that, notwithstanding pigeon-houses are common on many farms, it is, in very few instances, that this kind of stock, when the various disadvantages of it are considered, can be converted to much profit by the farmer. And it has been well remarked by Mr. Pitt, in his Corrected Report of Staffordshire, that the increase of pigeons beyond a certain degree must, doubtless, be injurious to the cultivation of grain; within due bounds they do little harm; but increased beyond it, they prove pernicious vermin, both to the new sown crops, and the early part of harvest. They are particularly voracious in early peas; therefore, the advantages arising from their increase for consumption as food are more than counterbalanced by the mischief occasioned by their depredations. Mr. Kent also states that, in Norfolk, pigeons are much fewer than formerly, as many of the pigeon-houses have been dropped, on account of the injury which the pigeons do to thatched buildings. And the same is the case in Kent and other counties. They are particularly injurious to the grain crops first at the time of harvest, by settling in large flights upon the standing corn, and in this way doing more mischief by beating it down than by the quantity they consume, as Mr. Parkinson has noticed in his Experienced Farmer. It is stated, that where this sort of flock is kept warm sheltered, sunny situations are the most advantageous, as the pigeon delights in warmth, and in being exposed to the full influence of the sun. See PIGEON-HOUSE.

And it is also of importance in the economy of these birds that the floor of the house be nearly upon a level with the holes where they enter, and that these holes be not too large nor too numerous; the holes where they form their nests should not be much enclosed, as pigeons delight in being at liberty. Salts and strong scents, such as *assaetida*, are said to be agreeable to these birds, so as frequently to attach them to their habitations, when they would not under other circumstances.

Birds of this kind seldom lay more than two eggs at one laying, sitting about twenty days, the male and female alternately. They are capable of breeding frequently, but in general only produce two or three broods or flights in the year. Of all the several sorts the common blue pigeon is probably the most productive. The tumblers are small but very domestic. The writer of the Experienced Farmer, after recommending the harvest flight as the most proper for the purpose of stock, as being the strongest to withstand the winter season, gives the following directions on the management of them; in regard to feeding them, it is advised as only necessary during the season between seed time and harvest, when it should be done by three or four o'clock in the morning, as they rise early. If you serve them much later, they will keep hovering about home, and be prevented taking their necessary exercise. If fed the year round, they will not feed near so well as if forced to seek their own food, for they pick up in the fields what is pleasant and healthy to them, and from the beginning of the harvest to the end of seed time they find plenty. They may be fed with tares, grain,

grain, or seeds of any kind. He directs us to be cautious of not letting the first flight fly to increase the stock, but let every one of them be taken; as these will come in, in what is called benting time, that is, between seed time and harvest. It is then that pigeons are the scarcest; and many of the young ones would pine to death through weakness during that season, and that, at the latter end of every flight, care should be taken to destroy all those eggs which were not laid in a proper time. The proper time for the spring flight is in April and May. After the harvest flight cold weather begins to come on, which injures the old pigeon much if she sits late; and the young will be good for nothing if hatched.

And it is very necessary to pay attention to cleanliness in the management of the dove-cote, as already noticed. Before breeding time the holes ought to be carefully examined and cleaned, for if any of the young die in the holes in the summer time, maggots are soon bred in them; they become putrid, and emit a putrid and unwholesome stench, very injurious to the inhabitants of the dove-cote. Pigeons are tenacious of their nests, as appears from the conduct of the wood-pigeon, which will breed for years in the same tree, and the mother forsakes her nest with regret; but, unable to endure the filth and stench of her dead offspring, she is obliged to quit the eggs she has laid for a second brood, and the prime of the season is lost. Every summer, immediately after the first flight, the nests should be all cleaned out, and the dung totally taken away, as it breeds filth. But remember to do this business early in the morning. The remaining eggs ought likewise to be destroyed, and a perfectly clean habitation made for the harvest flight of these birds. It is directed never to go into a dove-cote later than mid-day, but as early in a morning as convenient. Whatever repairs are necessary, either to the building or to the nests, should be done before noon; for if you disturb the pigeons in the afternoon, they will not rest contentedly the whole night; and the greatest part perhaps will not enter the cote until the next day, but will sit moping on the ground; and if in breeding time, either a number of eggs may be spoiled, or several young ones starved to death. It is added, that pigeons are supposed to be more productive from the breeds being crossed; in proof of which, a few tame pigeons were put into a dove-cote; and the consequence was, that a more early, and a more numerous hatch of young were produced than in any of the neighbouring cotes at the same season. It is also farther stated that these birds have a great antipathy to owls, which find their way sometimes into dove-cotes; and there is no getting rid of such troublesome guests but by destroying them. Rats are terrible enemies to pigeons, and will soon destroy a whole dove-cote. Cats, weasels, and squirrels will do the same. It will be necessary, therefore, to examine the dove-cote once every week at least, very minutely, to see that there are none of these intruders in the houses where they are kept.

In some cases, in order to catch and destroy pigeons, where they become troublesome to the farmer, it has been directed to take a good number of small twigs, and bird-lime them well, laying them on the ground where pigeons, &c. frequent, and they will soon be entangled with them; and, in order to allure them to the twigs, two or three pigeons may be tied to the ground, among the twigs. And another mode is to cut some sheets of thick brown paper, each into about eight parts, making them up into the shape of a sugar-loaf, and bird-liming the inside of them three or four days before intending to use them; putting into each paper, near the bottom, three or four grains of corn, and laying these papers up and down the ground, as much

as you can, under clods of earth, early in the morning before the pigeons, &c. come to feed. When the pigeons come to feed on the corn, by thrusting in their heads to reach it, they get hood-winked by the paper sticking to their heads, which occasions them to take wing, and fly upright till they have spent themselves, when they tumble down and may be easily taken. But the gun is probably the best method in such instances.

PIGEON, *Barbary*. See BARB.

PIGEON, *Helmet*. See HELMET.

PIGEON, *Laughing*. See LAUGHTER.

PIGEON, *Mahomet*. See MAHOMET.

PIGEON-Dung, in *Agriculture*, a manure of the bird dung kind, which is supposed to possess many valuable properties. It is sometimes turned in like other light substances in the spring, and costs about one shilling a bushel, heaped, in some districts, and about a halfpenny a bushel more bringing to the land; it is used also as malt dust, and answers in all seasons. See MANURE, and TOP-DRESSINGS.

PIGEON-HOUSE, in *Rural Economy*, a building, or house, erected for the purpose of keeping and breeding of pigeons, &c. It is sometimes called a dove-cote. In order to erect a pigeon-house to advantage, it is necessary, in the first place, to pitch upon a convenient situation, of which none is more proper than the middle of a spacious court-yard, when it is sheltered, and has a southern aspect. With regard to the size, it must depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too small; and as to its form, the round should be preferred to the square, because rats cannot so easily come at them in the former as in the latter. It is also much more commodious; as, by means of a ladder turning upon an axis, it is possible to visit all the nests in the house, without the least difficulty; which cannot be so easily done in a house of the square form. And in order to hinder rats from climbing up the outside of it, the wall should be covered with tin plates to a certain height, as about a foot and a half; which should project out three or four inches at the top, to prevent their getting up more effectually. It should be placed at no great distance from water, that the pigeons may carry it to their young ones, in a proper state and more conveniently. Where the house is covered with boards, they should be well joined together, so that no rain may penetrate through. And the whole building should be covered with hard plaster, and white-washed within and without. There must be no window or other opening in the pigeon-house to the eastward; these should always face the south; for pigeons are very fond of the sun, especially in winter. Other coverings are better than boards, as will be seen below. In regard to the nests or covers, they may consist of square holes made in the walls of a sufficient size to admit the cock and hen to stand in them; the first range of these nests being placed at a proper distance from the ground; and these nests should be placed in quincunx order, and not directly over one another. Nests may likewise be formed in other ways, as will be seen below.

It may be noticed that any lord of a manor may build a pigeon-house on his land, but a tenant cannot do it without the lord's licence. And that when persons shoot at or kill pigeons within a certain distance of the pigeon-house, they are liable to pay a forfeiture.

And it has been remarked in a late practical work, that where pigeons are bred for the purpose of deriving profit from them, the pigeon-house should not only be large and roomy, but be placed in such a situation that the pigeons may be fed with convenience, and without being disturbed by the different operations that are constantly going on about

the farm-house. The form of the house is probably not a matter of much consequence, provided it be not made too deep in the inside; pigeons disliking to have their necks low down. The floor should be closely laid, and the sides well plastered, to keep out vermin. The roof may be covered by any convenient and suitable material, but tiles and slates are by much the best; thatch, being warm in winter and cool in summer, may also afford a very good covering. The great objection to thatch for dove-cotes is, that the pigeons are apt to scratch it off; but when the ridge is secured by ridge-tiles, and very light hurdles are laid on each side of it, that inconvenience may be prevented. The whole must be made perfectly secure against the entrance of rats and other vermin. Where buildings of this sort are quite detached from the other offices, it is, perhaps, the best and cheapest method to erect them on pillars of brick or stone, or strong posts of wood, about six or seven feet high from the ground. In the latter case the upper parts of the house may likewise be principally composed of wood; and the under part will serve as a shed for various useful purposes. If a stable or cow-house the better, as it will have a tendency to keep the pigeons warmer in winter, which is material to their breeding early in the spring, when they are of most value in the market. The chief objection against wood cotes are, their being too cold in the winter, and too hot in the summer months. It is further stated, that the apertures or openings for the entrance of the pigeons, should always have a southern aspect, as they delight in a sunny situation, as observed above, and they ought not to be too large; the common size is larger by much than is necessary. The number of holes must be regulated by the quantity of birds that are intended to be kept; it is better, however, to have too few than too many; as a great number of holes renders the dove-house cold, and in any case but few are made use of by the pigeons. Above these holes a piece of weather boarding, sufficiently large for keeping off the wet, should constantly be fixed up. These boards are generally made so small that they do not keep off the wet effectually from the pigeons. And though it is the general practice to make square holes of board for the pigeons to lay and breed in; a neater method is that of employing small wicker baskets open at the top for this purpose; these baskets may either be composed of finer or coarser materials according to the inclination of the builder, or the expence he wishes to be at. Nests made in this way take up but little room, and are readily removed, whenever it is necessary to clean them, especially if they be fixed up in a convenient method for the purpose. Convenience should always be particularly attended to in buildings of this kind.

PIGEON-Holes, in *Brick-making*. See **BRICK**.

PIGEON-Pea, in *Botany*. See **CYTISUS**.

PIGEON Creek, in *Geography*, a river of America, which runs into the Ohio, N. lat. 37° 44'. W. long. 88° 6'.

PIGEON House, a name given by Capt. Cook to a mountain of New Zealand, from a supposed resemblance. N. lat. 35° 19'. W. long. 209° 42'.

PIGEON Island, an island in Dusky bay, New Zealand, S. of Facile harbour.—Also, a small island in the bay of Bengal, near the coast of Cicacole. N. lat. 17° 34'. E. long. 83° 23'.—Also, a small island in the East Indian sea, near the coast of Canara. N. lat. 14° 2'. E. long. 74° 5'.—Also, a fortified island in Port Royal bay, Martinico.—Also, an island near the E. coast of Ceylon; 10 miles N.N.W. of Trincomaly.

PIGEON River, a river of the state of Tennessee, which runs into the French Broad river, N. lat. 35° 46'. W. long. 82° 56'.

PIGER HENRICUS, slothful Harry, a fantastical name for a slow distilling chemical furnace; called also an *athanor*.

PIGGERY, in *Rural Economy*, a term applied to the place where hogs or swine are lodged.

In *Plate XL. fig. 1.* on *Agriculture*, is seen the plan of one-half of the duke of Bedford's piggery at Woburn Abbey: *a, a, a, a, a, a*, sties; *b, b, b, b, b, b*, troughs; separated by strips of wood generally into six divisions, but occasionally into a greater number when the pigs are small; *c, c, c, c, c, c*, gates which separate the sties and shut them up, as shewn by the dotted curved lines, when cleaned, &c.; *d, d, d, d, d, d*, gutters which convey the urine and liquid filth into the receptacles *e, e*; *f*, a boiler for potatoes, meal, &c.; *g, g, g*, chests for peas, meal, &c. *Fig. 2.* a section through the dotted line A B. The doors in cold weather are partially closed by hatches which turn down on hinges; one of them is shewn in that state at *k*; *l* the boiler. *Fig. 3.* is a section through the dotted line C D; *m, m*, troughs; *n*, one of the gates; that on the other side is supposed taken off to shew the door *o*; *p, p*, gutters. *Fig. 4.* a section of one of the troughs on a larger scale; *q, q*, the hatches, as turned up in mild weather.

This form of piggery is very neat and convenient for many different purposes in the rearing and keeping of swine. See *HOG-flie* and **SWINE**.

PIGGIN, a provincial term applied to a little pail or tub with an erect handle, for milking in, and other uses. See **PAIL**.

PIGHIUS, STEPHEN-VINAND, in *Biography*, a learned antiquary, was born in 1520, at Campen, in Overysfel. He was maternal nephew of Albert Pighius, whose family name he assumed. A residence of eight years at Rome gave him an accurate knowledge of the remains of antiquity in that capital. On his return to Germany he attached himself to cardinal Granvelle, whom he served in the character of secretary for fourteen years, and finally became a canon regular in his own country, and died in 1604. He obtained a high reputation for antiquarian knowledge, and the purity of his Latin style. He composed two Roman calendars from fragments in the Capitol, and wrote commentaries on the Fasti. He also published "Hercules Prodicus," containing the history and travels of Charles, duke of Cleves, proposing it as a kind of model of the education of a young prince. Some pieces of his writing are inserted in the collection of Gronovius. Moreri.

PIGHTLE, in *Rural Economy*, a provincial term applied to a small inclosure or croft.

PIGMATHA, in *Geography*, a town of Russia, in the government of Olonetz, on the N. coast of lake Onerskøe; 16 miles S. of Povenetz.

PIGMENTS, **PIGMENTA**, preparations in a solid form, used by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours.

These require to be mixed with some fluid, as a vehicle, before they can be employed as paints, except in the case of crayons, where they are used dry.

When glass is stained, or coloured, as in painting on glass, or for counterfeiting gems, or precious stones, the pigment is always of a metalline, or a mineral nature.

In the gilding of wood, pigments approaching as near as may be to the colour of gold itself are both laid under the gold, and used also for the colouring of depressed parts, where gold-leaf cannot be conveniently applied. The substance chiefly employed for this purpose is yellow ochre, the colour of which may be improved by a small addition of vermilion or other red powders. See **GILDING**.

PIGMY, or **PYGMY**. See **PYGMY**.

PIGNATA,

PIGNATA, in *Commerce*, a measure for oil at Naples; 320 pignate being = 16 staja = 1 palma = 325 lb. avoirdupois.

PIGNE, in *Geography*, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Monaco; 20 miles N.E. of Nice. The place contains 2285, and the canton 2285 inhabitants, on a territory of 52½ kilometres, in 1 commune.

PIGNE, in *Botany*. See **PINEA**.

PIGNEROLA, or **PINEROLA**, in *Geography*, a town of France, in the department of the Po, late capital of the province of the Four Vallies in Piedmont, near the Cluson, the key of Italy, and fortified; 16 miles S.W. of Turin.

PIGNOLETTI, in *Ichthyology*, a name used by many for the *apnya cobites*, a small fish of the gobioid or sea-gudgeon kind, common in the Mediterranean, and brought to the markets of Rome and Venice. See **GOBIUS Minutus**.

PIGNORIA, **LORENZO**, in *Biography*, a learned antiquary, was born at Padua in 1591. He was brought up among the Jesuits, and became confessor to a nunnery, and parish priest of St. Lorenzo. A canonry of Treviso was also conferred upon him by cardinal Fr. Barberini. He was in habits of intimacy with many of the most illustrious men of his time, and collected a valuable library and cabinet of antiquities. He died of the plague in 1631. His works are highly esteemed; the chief are, "De fervis et eorum apud Veteres Ministeriis;" "Menfa Isiaca," which is an elaborate commentary upon a famous relic, and three Latin letters to the senator Domenico Molino. Moreri.

PIGRIN, in *Geography*, a Russian settlement, on the W. coast of America, in Beering's strait. N. lat. 65° 54'. E. long 191° 40'.

PIGRITIA, in *Zoology*. See **BRADYPUS Tridactylus**.

PIGUS, in *Ichthyology*, the name of a species of leather-mouthed fish, very much approaching to the nature of the carp.

It is of the same shape and size with the common carp, and its eyes, fins, and fleshy palate wholly the same; from the gills to the tail there runs a crooked dotted line; its back and sides are blueish, and its belly reddish; it is covered with large scales, from the middle of every one of which there rises a fine, pellucid, and very sharp prickle.

It is a finer fish than the carp for the table, and is in season in the months of March and April. It is caught in lakes in some parts of Italy, and is mentioned by Pliny, though without a name.

It is a species of cyprinus, according to Artedi, and is distinguished by that author under the name of the cyprinus called *piclo* and *pigus*. He adds, that the tail is forked, and the scales large; and that in spring and autumn there grow out of them white pyramidal prickles, which remain about five or six weeks, and then fall off; the back is of a blackish-blue, and the belly white, with a faint cast of red. It never grows to more than five or six pounds; the flesh is well tasted. It is found in the lakes in the northern nations.

PIGWAKKET, in *Geography*, a town of America, in Maine, which runs into the Saco; 5 miles S. of Pigwakket.—Also, a town of America, in Maine; 27 miles N.W. of Portland.

PIHLAIS, a town of Sweden, in the government of Wafa; 83 miles S.E. of Wafa.

PIHTIPUDAS, a town of Sweden, in the government of Wafa; 105 miles E. of Wafa.

PIISKER, in *Ichthyology*, the name of a fish of the mustela kind, usually called the *mustela fossilis*, or *pisces fossilis*, the fossile fish. See **COBITIS Fossilis**.

This seems very much of the kind of the figum fish, and possibly is no other than the same species; and possibly also the *pæcilia* of Schonefeldt is the same.

PIKE, an offensive weapon, consisting of a shaft of wood, twelve or fourteen feet long; headed with a flat-pointed steel, called the *spear*. The general length fixed for the pike by most princes and states was, according to sir James Turner, in his "Pallas Armata," written in 1670 and 1671, 18 feet; but he observes that few exceeded 15.

The name pike is said to be derived from a bird called by the French *pic*, by us wood-pecker; whose bill is said to be so sharp as to pierce wood like an auger. Du Cange derives it from the base Latin *pica*, or *picca*; which Turnebus supposes to have been so called, *quasi spica*, because resembling an ear of corn: Octavio Ferraro derives it à *spicula*. M. Fauchet says, it was the pike that gave name to the Picards, and to Picardy; which he will have to be modern, and to have been framed on occasion of that people's renewing the use of the pike; the etymology whereof he fetches from the French *piquer*, to prick. But others will have the name *Picard* to have been given that people by reason of their readiness to pick quarrels; called in French *piques*.

The pike was a long time in use in the infantry, to enable them to sustain the attack of the cavalry; but it is now taken from them, and the bayonet, which is fixed to the muzzle of the firelock, is substituted in its place.

It is still used by some officers of infantry under the name of *spontoon*.

Pliny says, the Lacedæmonians were the inventors of the pike. The Macedonian phalanx was evidently a battalion of pike-men.

Father Daniel says, that pikes are not mentioned in the histories of France before the reign of Lewis XI. Pikes were introduced into France by the Switzers. The use of the pike was abolished in France by a royal ordonnance, issued in the year 1703; and though the exact period when pikes were laid aside in England has not been ascertained, it appears by the "Gentleman's Dictionary," published in 1705, that the alteration of the pike for the musket must have taken place some time between the years 1690 and 1705.

PIKE, Half, in the *Military Art*, is the weapon carried by an officer of foot. It differs from a pike, because it is but eight or nine feet long, and the spear is smaller and narrower. See **SPONTOON**.

PIKE, in *Ichthyology*, a name given by us to the fish called by authors the *lucius* and *esox*, and by the old Greek writers *oxyrinchus*. See **ESOX Lucius**.

It is said, that the pike was introduced into England in the reign of Henry VIII. in 1537, when a pike was sold for double the price of a house-lamb in February. Besides fish and frogs, which are its usual food, it will devour the water-rat and young ducks. It is very fierce and voracious. This fish is very remarkable for its longevity: we read of one that was ninety years old, and of another, that was not less than 267 years old. See *Feeding of FISH, Pike-FISHING*, and **HUXING**.

PIKE, Land. See **LUCIUS Terrestris**.

PIKE-Pearch. See **LUCIO-perca**.

PIKE, Sea. See **MERLUCIUS** and **SUDIS**.

PIKE, a provincial word signifying a sort of stacklet or load cock of hay, &c.

PIKE, a name given in some counties to a prong, or what is generally called a fork, used for carrying straw, &c. from the barn, cocking of hay, &c.

PIKE, a term in the midland districts signifying to glean.

fering in several other particulars. It is a species of *CLUPEA*; which see.

The distinguishing characters of it are these: the body of the pilchard is less compressed than that of the herring, being thicker and rounder; the nose is shorter in proportion, and turns up; the under jaw is shorter; the back is more elevated; the belly less sharp; the dorsal fin of the pilchard is placed exactly in the centre of gravity, so that when taken up by it, the body preserves an equilibrium, whereas that of the herring dips at the head; the scales of the pilchard adhere very closely, whereas those of the herring very easily drop off. Pennant.

It is generally found swimming in vast shoals, and is caught in many parts of the English shores. Its flesh is better tasted than that of the herring. See *Pilchard FISHERY*.

PILCHOWITZ, in *Geography*, a town of Silesia, in the principality of Oppeln; 36 miles S.E. of Oppeln. N. lat. $50^{\circ} 10'$. E. long. $18^{\circ} 30'$.

PILCO MAYO, a town of Peru; 25 miles N.E. of Potosi.—Also, a river of South America, which, after a south-east course of about 600 miles, runs into the Parana, by two mouths, between S. lat. $25^{\circ} 40'$ and $26^{\circ} 20'$.

PILE, in *Antiquity*, a pyramid built of wood, whereon were laid the bodies of the deceased, to be burnt.

PILES, in *Hydraulic Architecture*, are beams of timber, or stakes of wood, driven firmly into the ground, for various purposes; as, for forming a first foundation for buildings, piers of bridges, &c.; in which cases they are driven quite down into the ground, or are cut off level with its surface, with a view of obtaining a solid bearing for the weight of the structure which is to be raised.

Amsterdam, and some other cities, are wholly built upon piles. The stoppage of the breach in the banks of the Thames at Dagenham, was effected by dove-tail piles; that is, by piles mortised into one another by a dove-tail joint.

Piles are not employed for foundations unless the ground is suspected to be unfound, or when the weight to be borne is exceedingly great. They act to make the foundation solid, by reaching deep into the earth, down to a more substantial stratum than that of the surface. Indeed, the manner of fixing the piles, by driving them by repeated blows of a powerful machine till they will go no farther, ensures that they come to a good bearing. There are instances of piles being driven down twenty-five feet, before they were thought sufficiently firm.

Piles are also used for making the faces of wharfs, banks of rivers, piers for the sea, &c. For these purposes they are driven in rows, but only a sufficient depth in the earth to make them stand firm, and support the planking or framing which is fixed against them. These piles are usually driven rather in an inclined position. For temporary defence against the water, in laying the foundation of bridges, &c. piles are always required. They are employed in different ways to form an enclosure, or water-tight wall, called a coffer-dam, round the area where the work is to be laid, and from which space the water is drawn by pumps. This is the most difficult of all kinds of piling; because it must stand a great height above the ground, have sufficient strength to resist the pressure of water, and be perfectly close and tight. In navigable rivers detached piles are driven, and very firmly fixed, to mark the enclosures where barges are to lay, and to send off others from them, as well as to moor them to.

Piles are in general formed of a square timber, tapering if the tree happens to be so, cut to a sharp point at one end, and shod with iron to enter the ground. The other end was bound by a strong iron hoop, to prevent the pile head split-

ing by the violence of the blows which drive it down. When they are to be driven quite below ground, small trees, if sufficiently straight, may be used without squaring; but for coffer-dams square piles are always used, except that for filling up a row between such square piles. When they are to touch each other, flat ones, called pile planks, are used; they are three or four inches thick, according to the depth of water, and have grooves formed in their adjacent edges, to receive tongues or slips of wood, which make the joints quite tight. To enclose an area for a coffer-dam, two rows or walls of piles are usually driven one within the other, at a distance usually equal to the depth of water they are driven in, or if the current is rapid, once and a half. The space between these is filled with clay, so as to form a mound or rampart of clay, defended on the outside and inside by wooden walls of piles. To make these walls, large square piles are first driven at a distance of ten or twelve feet asunder, in the line of the intended range of the dam; horizontal tie beams are then extended from one pile to the next, on the inside, each tie being notched into the piles, so that its outer edge is in a line with the inside of the groove for the plank piles, which are to be driven down to fill up the spaces between the piles, and will be guided by these ties to stand exactly vertical, and in a straight line. The first plank piles are begun to be fixed adjacent to the main piles, and thus they proceed from both ends of the space between the piles, till the planks meet in the centre, where the last plank is inserted, and being formed rather wedge-like, makes all the rest tight. The pile planks are cut inclined, or wedge-like on one side only, to form the point, by which means the point is the line of one of the edges of the plank. When a plank pile is to be driven adjacent to another, this edge is applied to the one already fixed, and then as it is driven, the inclined or wedge-like edge entering the ground, causes the pile to approach, and press very close to its neighbour, and it is chiefly by this means they are made to fit water-tight. The fillets are made by spiking a ledge or ruler of wood fast upon the edge of one plank, and a groove of corresponding depth and width is ploughed in the edge of the adjacent plank to receive it. Many different machines are used to drive piles into the ground; some of them are worked by a great number of men, who raise a heavy weight a small height, and let it fall upon the pile, till, by reiterated blows, they drive it to the required depth. The machine employed is extremely simple. A long thick plank of wood is fixed up close to the pile, having a mortise through the upper end, in which a pulley is fitted; a rope goes over this to suspend the rammer, which is a large block of hard wood, properly hooped, to prevent it from splitting. In rising and falling, it slides against the face of the plank, and is guided by irons, which are fixed to the ram, and are bent round the edges of the plank in the manner of hooks. The plank, when placed upright, is secured by guy ropes, in the manner of the mast of a ship; the end of the great rope which suspends the ram, has ten or twelve small ropes spliced into it, for as many men to take hold, and work it by; they raise the ram up two or three feet by pulling the ropes all together, and then letting them go, the ram falls upon the pile head. When the pile becomes firm enough to cause the ram to rebound, they take care to pull the ropes instantly after the blow, that they may avail themselves of the leap it makes.

This is the simplest form of the machine. Others, instead of a plank, have two upright beams attached together, at such a distance asunder, as to leave an opening between them, for the reception of a piece of wood which is affixed to the ram, and by this means it is guided. Instead of guy ropes, these

these are usually fixed upon a base, consisting of a triangular frame, upon one angle of which the uprights are erected; and from the other two angles, braces arise, which are so inclined as to reach the uprights at half or two-thirds of their height to steady them. This plan is very convenient for driving piles in corners; but for driving rows, it is more advantageous to have the uprights fixed at the middle of one side of the triangular base, and have stays from all the three angles. A machine of this kind, with a ram of beech four feet long and one foot square, may be worked by ten or twelve men, at the rate of twenty-four blows *per* minute, and fixes the pile very quickly.

To estimate the force of the rammer made use of to drive piles, its weight ought to be multiplied into the velocity it acquires in falling. Thus, if a rammer which weighs 500lb. be let fall from four feet, it will fall that height in half a second, and have at the time of percussion a velocity capable to carry it uniformly eight feet in half a second, without any farther help from gravity; so that we must multiply 500 by 16, or its weight by the number of feet it would fall in a second, and the product 8000 gives the momentum of the stroke. If a capstan, pulleys, or windlafs, be made to raise the rammer to a considerable height, and then, by an easy contrivance, loosen it at once from its hook, the momentum of the stroke will always be as the square root of the height from which the rammer fell.

Notwithstanding the momentum, or force of a body in motion, is as the weight multiplied by the velocity, or simply as its velocity, when the weight is given or constant; yet the effect of the blow will be nearly as the square of that velocity; the effect being the quantity the pile is driven into the ground by the stroke. For the force of the blow, which is transferred to the pile, being destroyed in some certain definite time by the friction of the part which is within the earth, which is nearly a constant quantity, and the spaces in constant forces being as the squares of the velocities; therefore, the effects which are those spaces sunk, are nearly as the square of the velocities, or, which is the same thing, nearly as the heights fallen by the ram or hammer to the head of the pile. See upon this subject Leopold, Beldor, also Defaguliers's Exper. Philos. vol. i. p. 336, and vol. ii. p. 417, and Philos. Trans. 1779, p. 120.

For large works, such as bridges, &c., the piles are driven by a different kind of machine: this has a very heavy iron ram, with mechanical powers, by which it is raised to a considerable height, and then let fall, instead of continually repeating small blows. These are sometimes worked by horses, or steam-engines: see elevations of one, in *figs.* 1. and 2, *Plate XXXV. Mechanics.* A, A, are the uprights, erected on the frame B, and supported by the braces C; they are connected by the cross feet *a* at bottom, and the piece D at top; in this the pulley *b* for the rope *d* is fitted. Fillets of iron are fixed within the uprights A, A, and enter grooves made in the edges of the great iron ram E, which is thereby guided as it rises and falls: F is a piece, called the follower, (see *figs.* 3 and 4.) it is a wooden block, sliding between the uprights, and mortised to receive the iron tongs *e*, which take hold of an eye upon the top of the cast iron ram: the rope is attached to the follower by an iron loop *f*, through which the centre pin of the tongs passes. On the base, *a* B, of the machine an iron frame is bolted, to contain the windlafs G, on which the rope *d* winds. On the end of the windlafs a cog-wheel, *g*, is fixed, and a pinion upon the axis, *h*, engages its teeth. Motion is given to the spindle *b* by the winches *k*, fixed on each end of it, and the fly-wheel, *l*, regulates its motion, when turned by two men at each handle. The pile is of course included in the space between the two

uprights, A, A, before it is driven down; and the ram, being engaged by the tongs *e*, is drawn up by turning the handle, *k*, till the tails, *n*, of the tongs come to the inclined planes *m*, *fig.* 1: by these they are closed together, which opens the lower ends, disengages them from the eye of the ram, and it falls upon the head of the pile immediately. The men at the handles shift the spindle *b* endways, which disunites the pinion from the wheel, and then the weight of the follower, F, runs back the windlafs G, and descends till its tongs take hold of the ram, ready to take it up again. The inclined planes, *m*, are not fixed to the uprights A, A, but are connected together by pieces of wood, which embrace the uprights, and these have holes through them to receive iron bolts, which also pass through the uprights. By this means the inclined planes can be shifted, to let them at any required height, that they may, by discharging the ram at the proper height, give a blow proportioned to the pile which is to be driven by it. The tongs are sometimes made with rollers in the ends *n, n*, as shewn in *fig.* 12, that they may act more easily in the inclined planes. Other machines have a kind of latch, shewn in *fig.* 11, instead of the tongs; in this *f* represents the iron loop for the rope; the centre pin of it passes through the latch *r s t*, which catches the eye of the ram by the hook *t*, and is discharged by the line *r*, when the men snatch it. The weight *s* is to cause the hook to catch; the loop *f* is attached to a wooden follower, which guides it between the uprights.

Machines of this kind are frequently actuated by steam-engines. A pulley, which is fixed on the end of the spindle *b*, in place of the handle *k*, receives an endless rope from some wheel put in motion by the engine; one man then attends it, to throw the spindle endways at the proper time, to permit the descent of the follower; but we have seen one in which levers, and a connecting rod from the inclined plane, *m*, were used to disengage the spindle the moment after the follower discharges the ram; by adopting these means much expence of labour would be saved, as the same steam-engine which is afterwards to be employed in pumping out the water of the coffer-dams, would drive the piles for them and the foundations.

The piles of the works of Westminster-bridge, whilst it was building, were driven by a horse-machine invented by Mr. Valoué. A pair of the uprights, such as represented at *figs.* 1 and 2, but thirty feet high, were erected at one end of a frame, which supported a vertical shaft, turned round by the horses, and the framing was of course large enough to admit a circular walk of sufficient size for them to work in, when they drew the ends of arms or levers projecting from the vertical shaft. The whole was erected upon a platform, which was built over a barge in the manner of a deck. The vertical shaft had a wheel or drum upon it, to wind up the rope of the follower, and it was in the construction of this part that the invention lay. A section of the upper part of the vertical shaft and drum is given in *fig.* 8, and a plan in *fig.* 9. Here A is the great upright shaft, or axle, turned by the horses attached to the levers, which are not shewn. The cog-wheel, B, turns the pinion X, having a fly, O, at the top to regulate the motion, and to act against the horses, and keep them from falling, when the heavy ram is disengaged to drive the pile down into the earth in the bottom of the river. The drum, C, is loose upon the axle of the shaft A, but is locked to the wheel, B, by the bolt Y. On this drum the great rope, H, is wound, one end of it being fixed to the drum, and the other to the follower, passing over proper pulleys. In the follower are contained the tongs, which take hold of the ram, by the staple for drawing it up, in the same manner as described in *fig.* 2;

PILE.

D is a spiral, or fufee fixed to the drum C, on which winds the small rope T: it goes over a pulley, and has a small counterpoise hung to the end of it, which hinders the follower from accelerating as it goes down to take hold of the ram; for as the follower tends to acquire velocity in its descent, the line, T, winds downwards upon the fufee on a larger and larger radius, by which means the counterpoise acts stronger and stronger against it; and so allows it to come down with only a moderate and uniform velocity. The bolt, Y, locks the drum to the great wheel, being pushed upwards by the small lever 3, which passes through a mortise on the shaft A, and turns upon a pin; the lower end of the bolt is guided by passing through a piece of wood, 6, fixed into the great shaft, and the upper passes through an arm of the wheel; the lever, 3, has a weight, 4, which always tends to push up the bolt, Y, through the wheel into the drum; G L is the great lever, turning on the centre m, and resting its end, G, upon the forcing bar 5, which goes down through a hollow in the shaft A, and bears upon the little lever 3. The other end of the lever, L, is long enough to reach to the uprights, and has there a small rope, extended from the end of it up to the inclined planes, so that the follower, when drawn up to the highest, draws this rope, and raises the long end, L, of the lever, depressing the other, and the forcing bar 5. By the horses going round, the great rope, H, is wound about the drum C, and the ram is drawn up by the tongs in the follower, till they come between the inclined planes, which, by shutting the tongs at the top, open them below, and so discharge the ram, which falls down between the uprights upon the pile, and drives it by a few strokes as far into the ground as it can go, or as is desired; after which the top part is sawed off close to the mud, by an engine for that purpose. Immediately after the ram is discharged, a piece upon the follower takes hold of the rope, which raises the end, L, of the lever L G, and cause its end, G, to descend, and press down the forcing-bar, 5, upon the little lever, 3, which by drawing down the bolt Y, unlocks the drum, C, from the great wheel B; and then the follower being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs slip over the eye of the ram, the weight of their heads causing them to fall outwards, and fasten upon it; then the weight, 4, pushes up the bolt, Y, into the drum, which locks it to the great wheel, and so the ram is drawn up as before.

As the follower comes down, it causes the drum, C, to turn backward, and unwinds the rope from it, while the horses, the great wheel, pinion X, and fly, go on with an uninterrupted motion; and as the drum is turning backward, the counterpoise is drawn up by its rope, T, winding upon the spiral fufee D.

There are several holes in the under side of the drum, and the bolt, Y, always takes the first one that it finds, when the drum stops by the falling of the follower upon the ram, till which stoppage the bolt has not time to slip into any of the holes. But the same effect is more certainly produced by a crooked lever, *t*, *fig. 9*, fixed on the framing R, over the end of the vertical shaft; one end of this has a roller, which is pressed upon by the great rope, H, the other end holds down the catch, 5, of the forcing-bar, but as soon as the great rope slackens, it retires, and gives liberty to the small lever, 3, to push up the bolt. As long as the great rope has a tension upon it, to support the weight of the ram or follower, the crooked lever is kept in close contact with the forcing-bar, and when that is depressed, (to discharge the bolt Y,) by locking over its catch, 5, the crooked lever keeps it down, till the follower touches the

ram; the great rope then slackens, and the spring, *v* H, discharges the crooked lever from the catch of the forcing bar, and gives liberty to the small lever, 4, to push up the great bolt, and to lock the drum to the great wheel, and the ram is drawn up again as before.

The peculiar advantages of this engine are, that the weight of the ram, or hammer, may be raised with the force of horses instead of men; that when it is raised to a proper height, it readily disengages itself, and falls with the utmost freedom; that the forceps or tongs are lowered down speedily, and instantly of themselves again lay hold of the ram, and lift it up; on which account this machine will drive the greatest number of piles in the least time, and with the fewest labourers.

The piles at Westminster bridge, when driven by the above machine till they were quite firm, were cut off, under water, by a machine, to be level with the surface of the ground to found the piers upon. This machine consisted of a framing which was adapted to fit upon the upper part of the pile, and could be fixed fast thereto. The lower part of this frame formed guides for the saw, which reciprocated horizontally at a certain depth beneath the top of the pile, and had weights to cause it to advance up to the cut. The saw was put in motion by ropes from each end, which were conducted, over proper pulleys, to two men standing on a float or raft at the surface. After fixing the machine, before the sawing was begun, the whole machine was suspended by a tackle, which therefore took up the top part of the pile with the machine as soon as it was cut off. This was the invention of Mr. Etheridge, carpenter to the works at Westminster bridge; it was very effective, as the time employed in cutting off a fir pile of 14 or 16 inches square, in ten feet depth of water, was seldom more, and often less, than a minute and a half. A machine, more convenient than this in its application, and not less effective, has been since invented by Mr. Foulds, to whom the Society of Arts presented a gold medal for the invention; see *figs. 5* and *7*. A A B is the external frame, consisting of four parallel rails A, framed into two others, B, at right angles, with proper cross pieces to unite them, and inclined to strengthen the whole; within this frame a second, or internal frame, D E, is situated; like the other, it has four parallel pieces, D and E, connected together into one frame by cross pieces; at the top it has two pieces *a, a*, which rest upon the beam B, and suspend its weight, and on these it is capable of sliding backwards and forwards between B B, always preserving its parallelism, because it is moved by the racks, *d, d*, affixed to it, one at top, and the other at the bottom; the pinions for both are fixed on a vertical axis *e*, supported in the external frame; therefore, by turning the handle *r*, the internal frame with the saw is advanced to the pile, as at K, *fig. 6*. The saw itself is sustained in a frame L, *fig. 7*, which fits, in the manner of a fash frame, between the two beams, D, of the internal frame, and has racks, *f, f*, (dotted) behind it, which work in pinions on an axis *g*, extended across the frame, and by the handle, *y*, of this it is capable of being drawn up and let down, or detained at any height by a ratchet-wheel and click *x*; the saw, *m*, is fixed upon a spindle N, supported in bearings on the frame L, and turned by the handle, R, at the top; the saw is connected with the spindle by a piece of iron *p*, having a mortise through it for the reception of the spindle, to which it is fastened by a nut beneath: by this means the saw's edge may be advanced as the work goes on.

In using this machine, the beams, B, are fixed across a barge, which is ballasted till they are horizontal, and the spindle of the saw is therefore vertical in this state; it is moored with her side against the pile, K, to be cut off, as

shewn by the dotted line V, *fig. 6*; then by the rack and pinion *f g*, the saw is adjusted in height to the level where the pile is to be cut; by the handle *r* it is advanced to the pile K, whilst by the other handle, R, the saw is kept in continual motion backwards and forwards, till the pile is cut through, and the piece is taken into the barge, which proceeds to cut off the next by the same means. By this machine temporary piles, which are used in coffer-dams, may be cut off level with the bottom, when the work is finished, which is a very superior method to drawing them up out of the ground, as is the usual practice, because this must necessarily make a deep ditch or trench all round the pier or foundation, and tend to loosen the ground. To draw piles out of the ground when they have been driven fast, requires a very great force. There are different methods of exerting this force: one for drawing them in water, is by having a very strong barge, with a windlass at one end to receive a strong chain, which is passed several times round the head of the pile, and made fast to the barge; two long beams are laid upon the barge to form a railway for a small waggon to run upon from one end of the barge to the other, and it is loaded with stones of several tons weight; when this is wheeled to one end of the barge, it will of course depress it in the water, elevating the other; then, in this state, the lowest end of the barge is chained to the pile by putting a very large bolt through it, and passing a chain round the pile under this bolt a great many times; the carriage is then wheeled to the other end of the barge by a windlass and rope; this tends to raise the end to which the pile is fixed; and when the carriage is so far advanced that it exerts a sufficient power, it will draw up the pile if the chain is properly fixed: the carriage is now returned to draw another pile.

A plan has been adopted at the new bridge now building across the Thames at the Strand, for drawing the useless piles by one of Mr. Bramah's hydrostatic cylinders. This is represented in *fig. 10*, where A is supposed to be the top of a range of piles forming the coffer-dam, and B the pile which is to be drawn. A chain, *a*, is made fast to the pile, and carried many times round a large beam CD, the end, D, of which rests upon a fulcrum, or support E, consisting of a block, supported on the head of a neighbouring pile, &c. F is a block of wood, screwed together in two places, and inclosing between them a cast iron cylinder *b*, into which is fitted the piston, or cylinder *d*, the joining being made tight by a collar of leather; *e* is a small copper pipe, communicating with the cylinder, and also with a small forcing pump, the piston, *f*, of which, is actuated by the lever *g b*; the pump is fixed upon the top of a small cistern, *k*, to contain water. Now by working the lever of the pump, water is injected into the cylinder *b*, and protrudes the piston, *d*, from it with a force proportioned to the force exerted upon the lever, in the same degree as the areas of the pump to that of the cylinder multiplied by the proportions of the lever *b*. (See this principle more fully illustrated under MACHINERY, and PRESS, *Hydrostatic*.) By this means the power of one or two men is increased to such a degree, as to draw up the largest pile; the copper pipe, *e*, is made to unscrew at several joints, which are provided with leather, to make them tight; by this means the pump is separated when the machine is to be removed. As it has no connection with the beam or lever D, the cylinder is frequently employed in the manner of a hand jack, for any purposes where enormous weights are to be lifted for a small space; the collars of leather are the same as are used in the presses. The same figure also shews a very complete way of catching fast hold of the pile, instead of putting a bolt through the pile head

to stop the chain under: it is simply a strong iron ring, *l*, large enough to drop over the pile loosely, and having a strong shank or eye, *m*, projecting from it to run the chain through; and when this is drawn, the ring jams so forcibly upon the wood of the pile, as to draw it out of the ground rather than slip off, for it holds faster in proportion to the force.

The theory of Mr. Valoue's engine depends on the following principles, *viz.* 1. If the resistance of the ground, and the masses of the piles be equal, the depths to which they will be driven with a single blow will be as the product of the weight of the ram into the height through which it falls.

2. If the masses of the ram, and heights through which it falls are both equal, the depths to which the piles will be driven, will be in the inverse ratios of the masses of the piles into the superficies of that part of them which is already immersed in the earth.

3. If all these things be unequal, the depths will be in a ratio compounded of the direct ratio of the heights through which the ram falls into its mass, and the inverse ratio of the mass of the pile into its immersed superficies.

4. If the weights of the ram be equal, and also the weights of the piles, the depths to which they will be driven will be as the heights through which the ram falls directly, and the immersed superficies of the piles. Or, because the immersed superficies of the piles are as the depths through which they are already driven into the earth, these depths are simply as the square roots of the heights through which the ram falls.

These principles are founded on the general supposition that the space through which the weight falls is estimated by the product of its mass into the square of its velocity, or into the height through which it falls.

Hence it is inferred, that the distance through which a pile will be driven by each succeeding blow will be less and less, as the superficies of that part of the pile which is immersed in the ground increases; and, consequently, that there is a certain depth, beyond which a pile of a given mass and scantling cannot be driven; the mass of the ram and the height through which it falls at first being assigned. It appears also, that the loading the pile with weights, and thereby increasing its mass, will be so far from accelerating its descent, that it will absolutely retard it. See some curious observations on the structure and operation of this engine by Mr. Bugge, professor of astronomy and mathematics in the academy of Copenhagen, &c. in the *Phil. Transf.* for 1779, vol. lxi. part 1. art. 12.

PILE is also used, among *Architects*, for a mass or body of building.

PILE, in *Artillery*, denotes a collection or heap of shot or shells, which are usually piled up by horizontal courses into a pyramidal form, the base being either an equilateral triangle, a square, or a rectangle. In the triangle and square, the pile terminates in a single ball; but in a rectangle, in a single row of balls. In the triangle and square piles, the number of horizontal rows, or the number counted on one of the angles from the bottom to the top, is always equal to the number counted on one side, in the bottom row. In triangular piles, each horizontal course is a triangular number, produced by taking the successive sums of the numbers 1 and 2; 1, 2, and 3; 1, 2, 3, and 4, &c.; and the number of shot in a triangular pile is the sum of all the triangular numbers taken as far, or to as many terms, as the number in one side of the bottom course. In order to obtain the number in a triangular pile, count the number in the bottom row, and multiply that number more two by that number

more one; and the product multiplied by one-sixth of the said number will be the whole sum required.

In square piles, each horizontal course is a square number, produced by taking the square of the number in its side; and the number of shot in a square pile is the sum of all the squares, taken from one as far as the number in the sides of the bottom course. To find the number, count the number in one side of the bottom course; to that number add one, and to its double add one; multiply the two sums together, then their product being multiplied by one-sixth of the said number, will give the required number of shot in the pile.

From the exemplification of these rules, it would appear, that when room is wanted, it is most convenient to flow the shot in triangular piles; for on the equilateral triangle, which is less than half the area of a square of one of its sides, there can be piled a greater number than half of those that can be raised on the square: and the height of a square pile is somewhat less than that of a triangular one; because a shot will sink lower in the space between four others, than between three others, when they are of equal diameter.

In rectangular piles, each horizontal course is a rectangle, the upper one being one row of balls; and every such oblong pile may be considered as consisting of two parts, one a square pyramid, and the other a triangular prism. To find the number of shot in a rectangular pile, take the difference between the number in length and breadth, in the bottom course; multiply the number in breadth, more one, by half the breadth; the product multiplied by the said difference will give the number in the prismatic pile; upon the square of the breadth, find the number in a pyramidal pile; and the sum of these two piles will give the number required. See CALIBER.

To PILE Arms, in *Military Language*, is to place three muskets with fixed bayonets in such a position with regard to one another, that the butts shall remain firm in the ground, and the muzzles lie close together in an oblique direction. This method has been adopted to prevent the injury which was formerly done to musketry, when the custom of grounding the firelock prevailed. Every recruit should be taught how to pile arms before he is dismissed the drill.

PILE, *Pila*, in *Coinage*, denotes a kind of puncheon, which, in the old way of coining, with the hammer, contained the arms, crosses, or other figure and inscription, to be struck for the reverse of the species.

Accordingly, we still call the arms-side of a piece of money the *pile*, and the head the *cross*; because, in the ancient monies, a cross usually took the place of the head in our's.

Hence also the game of *cross* and *pile*.

Some will have it called *pile*, *pila*, because on this side, in our ancient coins, there was an impression of a church built on piles. Scaliger, with more probability, derives it from the old French word *pile*, a *ship*. Vide prima Scaligerana, in voc. Nummus Raticus, p. 115.

In some ancient writings, *pila* is used to signify the particular figure, or impression of money. Thus Fleta: he who brings an appeal of robbery, or theft, against another, must shew the certain quantity, quality, price, weight, number, measures, value, and pile.

PILE, in *Heraldry*, is an ordinary, in form of a point inverted, or a stake sharpened; contracting from the chief, and terminating in a point towards the bottom of the shield, somewhat in manner of a wedge.

It is formed, probably, in imitation of the Roman pilum, which was a tapering dart, about five feet long, and sharpened at the point with steel.

The pile is borne inverted, engrailed, &c. like other ordinaries; and issues indifferently from any point of the verge of the escutcheon. He beareth a pile gules, by the name of Chandois.

PILE, in *Rural Economy*, a sharpened piece of wood driven down into the ground, to protect the banks of rivers, or other similar purposes. It should be strong, and well driven in. See PILE, *supra*.

PILE, a provincial word applied to the breaking off the awns of threshed barley.

PILE of *Grass*, a blade or small bit of grass.

PILE-Planks, are planks whose ends are sharpened, to drive into any canal or water, close to each other, in order to form a flank, by which the water may be stopped and discharged. See *Plate IV. Canals, fig. 30.*

PILE-Sheeting is the same with *dove-tail piling*.

PILE-Worms, are a kind of worms found in the piles of the sea-dikes in Holland. These worms are of various sizes: some of the young ones are not above an inch or two in length; but others have been found thirteen or fourteen inches long.

The heads of these creatures were covered with two hard shells or hemispheres, which together form a figure resembling an auger, and with which they bore the wood. The best remedy against them is, to perforate the piles with many small holes, about an inch asunder; then it must be done over with a varnish in the hottest sun; and while the varnish is hot, brick-dust must be strewed over it; and this being several times repeated, the pile will be covered with a strong crust, impenetrable to all insects. See a farther account of these creatures in *Phil. Trans. N° 455, sect. 5.*

PILEÆ, a name given by some authors to a genus of echinodermata.

PILENTUM, among the Romans, an easy kind of chariot, used by the Roman ladies at games and religious processions.

PILES, in *Surgery*. See HEMORRHOIDS.

PILES, *Liniment for the*. See LINIMENT.

PILESGROVE, in *Geography*, a town of America, in New Jersey, and county of Salem, containing 1756 inhabitants.

PILETTUS, in our *Ancient Forest Laws*, an arrow which had a round knob a little above the head, to hinder it from going far into the mark.

From the Latin *pila*, which signifies any round thing like a ball. "Et quod forestarii sui non portabunt sagittas barbatus, sed piletos." Charta Rogeri de Quincy.

PILEUS, in *Roman Antiquity*, was the ordinary cap or hat worn at public shows and sacrifices, and by the freed-men.

It was one of the common rewards assigned to such gladiators as were slaves, in token of their obtaining their freedom. See RUDIS.

PILEUS *Presbyteri*, in *Botany*, a name given by some writers to the euonymus or fusanus, a shrub which grows in our hedges, and bears a square fruit, somewhat resembling the cap worn by some orders of priests.

PILEWORT. See RANUNCULUS.

PILFUNTE, in *Geography*, a town of Abascia, on the Black sea; 16 miles S.S.W. of Anakopia.

PILGERRUN, or PILGRIM'S Rest, a Moravian town of Pennsylvania; 140 miles N.W. of Pittsburg.

PILGRAM, or PELDRZIMOW, a town of Bohemia, in the circle of Bechin. N. lat. 49° 28'. E. long. 15° 7'.

PILGRIM, one who travels through foreign countries to visit holy places, and to pay his devotion to the relics of dead saints.

The word is formed from the Flemish *pelgrim*, or Italian *pellegrino*, which signifies the same; and these originally from the Latin *peregrinus*, a *stranger*, or *traveller*.

The humour of going on pilgrimage anciently prevailed exceedingly, particularly about the time of the croisades. Pilgrimages were most in vogue after the end of the eleventh century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella, and Tours; but the greatest numbers resorted to Loretto, in order to visit the chamber of the blessed Virgin, in which she was born, and brought up her son Jesus, till he was twelve years of age.

This chamber, it is pretended, was carried by angels into Dalmatia, about the year 1291, and afterwards in the same manner transported to Loretto, where a magnificent cathedral is built over it. In this chamber is the image of the blessed Virgin, almost covered with pearls and diamonds; and round the statue there is a kind of rainbow, formed of precious stones of various colours. Five hundred thousand pilgrims have sometimes resorted to this house in one year, in order to pay their devotions before this glorious image.

Several of the principal orders of knighthood were established in favour of pilgrims going to the Holy Land, to secure them from the violences and insults of the Saracens and Arabs, &c.

Such were the orders of the knights Templars, the knights Hospitalers, knights of Malta, &c.

The Mahometans are commanded in the Koran (chap. 2, 3, 22.) to perform a pilgrimage to Mecca. This is one of the capital points of their religion, and therefore a prodigious cavalcade of pilgrims annually goes thither, in the company of those who are sent with the grand seignior's presents to the tomb of Mahomet.

So strictly is this duty enjoined, and so necessary is the performance of it, that, according to a tradition of Mahomet, he who dies without performing it may as well die a Jew, or a Christian. For an account of these pilgrimages, see CAABA, CARAVAN, and MECCA.

PILHANNAW, in *Ornithology*, a name given by the Indians to a bird found in the forests, on the back of some of our American plantations.

It is a bird of prey, very large and bold. It is described by Joffelin as four times as big as our goshawk, and having a remarkable large head. All the birds are terrified at its approach; but it principally feeds on quadrupeds, as young fawns, and the like.

PILIATCHIN, in *Geography*, a cape on the east coast of Russia, in the Penzinskoi sea; 272 miles E.N.E. of Ochotk. N. lat. 60° 10'. E. long. 155° 14'.

PILIMICTIO, a word used by several authors to express a discharge of small and long filaments, which resemble hairs, among the urine.

PILING. See PALLIFICATION.

PILING-Iron, a name provincially applied to a tool used in breaking off the awns of barley, and sometimes the tails of oats; an operation which with the farmers is called piling barley, and sometimes faultering it.

PILIO, in *Geography*, a town of Thibet; 67 miles N. of Tourfan Hotun.

PILIS, a town of Hungary; 8 miles S.E. of Gran.

PILKALLEN, a town of Prussian Lithuania; 64 miles E. of Königsberg. N. lat. 54° 45'. E. long. 22° 57'.

PILKOPEN, a town of Prussia, in the province of Szmland, seated on a mountain, where the ancients placed

an idol, called "Pilkob," which they worshipped; 30 miles N. of Königsberg.

PILKINGTON, a township of England, in Lancashire, containing 5786 inhabitants, including 3824 employed in trade and manufactures; 3 miles S. of Bury.

PILL, or CROCKERN *Pill*, a town, or rather village, of England, in the county of Somerset, on a point of land at the mouth of the Avon, where it joins the Severn at King-road, inhabited chiefly by mariners and pilots, who are employed in navigating vessels up the river, and down the Bristol Channel; 12 miles below Bristol.

PILL, *Pilula*, in *Pharmacy*, a form of medicine, taken dry, resembling a little ball; invented in favour of such as cannot well take ill-tasted medicinal draughts; as also to keep in readiness for occasional use without decaying.

Extracts, when not too hard, may be formed into pills, without any addition; but they are more generally composed of either vegetable, or earthy, or metallic powders, combined by means of syrup into a coherent mass. Salts may also be formed into pills, those that are deliquescent excepted; and when efflorescent salts are used, they should be first freed from the water of crystallization; because the pills formed with uneffloresced salts, which are apt to effloresce, fall into powder as they dry. The masses, which are kept prepared for the formation of pills, should be preserved in covered pots, wrapped in bladders, and occasionally moistened.

No medicine that is intended to operate quickly ought to be made into pills, as they often lie for a considerable time in the stomach before they are dissolved, so as to produce any effect.

Pills are of various kinds, anodyne, somniferous, laxative, aperitive, hysteric, antinephritic, &c.; but they are principally cathartic.

The basis of cathartic pills is usually aloes; with which are mixed agaric, turbit, hermodactyls, senna, rhubarb, colocynth. See *EXTRACTUM Catharticum*.

Pills are usually wrapped up in leaf-gold, wafer-paper, or the like, to prevent their ill taste being perceived; but as simple dry powders, as subcarbonate of magnesia or starch, answer all the purposes of this covering, it is now laid aside.

PILLS, *Compound Aloetic*, are to be prepared, according to the directions of the London dispensatory, by beating together, into an uniform mass, one ounce of extract of spiked aloes, half an ounce of extract of gentian, 40 minims of oil of carraway, and a sufficient quantity of syrup. The aloetic pills of the Edinburgh Pharmacopeia consist of equal parts of Socotorine aloes in powder and soap, beaten with simple syrup into a proper mass for pills. The pills of aloes and ginger of the Dublin Pharmacopeia are composed of an ounce of hepatic aloes, a dram of ginger-root in powder, half an ounce of soap, and half a dram of essential oil of peppermint: the aloes and the ginger are rubbed together into a powder, and then the soap and oil are added, so as to form a mass. These are useful pills, and administered with advantage for obviating the habitual colliqueness of the sedentary, and of leucophlegmatic habits. The dose is from grs. x to grs. xv, or more.

PILLS of *Aloes and Affasætida* of the Edinb. Ph., consist of equal parts of Socotorine aloes in powder, affasætida, and soap, beaten into a mass with mucilage of gum arabic. These pills are anodyne and cathartic, and have been found useful in dyspepsia, attended with flatulence. The dose is grs. x, given twice a day.

PILLS of *Aloes with Myrrh*, are formed, according to the Lond. Ph., of two ounces of extract of spiked aloes, of an ounce

PILLS.

ounce of saffron, and the same quantity of myrrh, and a sufficient quantity of syrup: the aloes and the myrrh are rubbed into powder separately, and then all the ingredients are beaten together into an uniform mass. According to the Dub. Ph., half an ounce of myrrh and an ounce of hepatic aloes are pulverised separately; then two drams of saffron and half a dram of oil of caraway being added to them, all the ingredients are beaten together into a mass. The same pills of the Edinb. Ph. are composed of four parts of Socotorine aloes, two parts of myrrh, and one part of saffron, beaten into a mass with simple syrup. These pills have been long used to stimulate and open the bowels in chlorotic, hypochondriacal, and cachectic habits. The dose is from grs. x to ℥j, given twice a day.

Pills of this kind are described by Rhazis, the Arabian, who ascribes the original form to Rufus, after whom they were first named, viz. "pilula Rufi."

PILLS of Ammoniac of Copper, of the Edinb. Ph., consist of sixteen grains of ammoniac of copper rubbed to fine powder, four scruples of crumb of bread, and a sufficient quantity of water of carbonate of ammonia, beaten into a mass, and divided into 32 equal pills. These pills are given in epilepsy, and other spasmodic diseases: at first, one pill night and morning is sufficient, but the number may be gradually increased till five be taken for a dose.

PILLS of Gamboge, Compound, are directed by the Lond. Ph. to be prepared by mixing together gamboge in powder, extract of spiked aloes in powder, compound powder of cinnamon, of each a dram, and then adding two drams of hard soap, and beating the whole together into an uniform mass. This preparation is much more active than the aloetic pills; the dose is from grs. x to ℥j, given at bed-time in obstinate costiveness.

PILLS of Iron with Myrrh, are composed, according to the Lond. Ph., of two drams of myrrh in powder, and subcarbonate of soda, sulphate of iron, and sugar, of each a dram: the myrrh is rubbed with the subcarbonate of soda, then, after having added the sulphate of iron, rubbed again, and then the whole is beaten into a mass. This is an useful emmenagogue pill; the dose is from grs. x to ℥j, given twice or thrice a day.

PILLS of Galbanum, Compound, of the Lond. Ph., consist of galbanum, an ounce; myrrh and sagapenum, of each an ounce and a half; assafœtida, half an ounce; and a sufficient quantity of syrup; beaten together into an uniform mass.

PILLS, Compound Assafœtida, of the Edinb. Ph., are composed of assafœtida, galbanum, and myrrh, of each eight parts, and of purified oil of amber one part; beaten into a mass, with simple syrup.

PILLS of Myrrh, Compound, of the Dubl. Ph., consist of assafœtida, myrrh in powder, and galbanum, of each an ounce, and of oil of amber half a dram; rubbed together, and made into a mass with simple syrup.

These preparations are useful antispasmodics and emmenagogues, and are given with advantage in chlorosis, hysteria, and hypochondriasis. The dose is from grs. x to ℥j, taken every night at bed-time.

PILLS, Mercurial, Pilule hydrargyri, often from their colour called the *blue pills*, are prepared, according to the directions of the London and Dublin Pharmacopeias, by rubbing two drams of purified mercury with three drams of confection of red roses, until the globules disappear; then adding a dram of liquorice root in powder; and beating the whole into an uniform mass. The Edinburgh Pharmacopeia directs them to be prepared by rubbing an ounce of

purified mercury with the same quantity of the conserve of red roses, in a glass mortar, until the globules entirely disappear, adding, if necessary, a little mucilage of gum arabic; then adding two ounces of starch, and beating, with a little water, the whole into a mass, which is to be directly divided into 180 pills of equal sizes. N.B. One grain of mercury is contained in four grains of the mass, prepared by the London and Dublin formulæ, and in three grains according to that of Edinburgh. These pills are stimulant and antisyphilitic, and are the most common form of preparation under which mercury is exhibited for the cure of venereal affections, as it is much less liable to act on the bowels than any of the other forms. The common dose is from gr. vi to gr. viij, or two pills, given twice a day till the mouth be affected. Larger doses are apt to excite purging.

PILLS of Submuriate of Mercury, Pilule hydrargyri submuriatis, of the London Pharmacopeia, are formed by rubbing a dram of submuriate of mercury (calomel) with the same quantity of precipitated sulphuret of antimony, then with two drams of guaiac gum-resin, and adding a sufficient quantity of copaiba to give the mass a proper consistence. This combination was first recommended by Dr. Plummer, in the Edinburgh Medical Essays, and distinguished in the Edinburgh Pharmacopeia, by the name of "Plummer's Pill." From this pharmacopeia it was afterwards expunged; but as it was much used in practice, it has a place in the London Pharmacopeia. It is a very useful alterative in lepra, in secondary syphilis affecting the skin, and in other cutaneous diseases. The dose is from grs. v to grs. viij, given night and morning.

PILLS, Compound Rhubarb, of the Edinburgh Pharmacopeia, are composed of one ounce of rhubarb root in powder, six drams of Socotorine aloes, half an ounce of myrrh, and half a dram of volatile oil of peppermint, beaten into a mass with syrup of orange-peel. This is a warm, stomachic, laxative pill, very useful for obviating costiveness, and at the same time giving tone to the bowels in dyspepsia and hypochondriasis. The dose is from grs. x to ℥j, given twice a day.

PILLS of Soap and Opium are prepared, according to the London Pharmacopeia, by beating together half an ounce of hard opium powdered, and two ounces of hard soap, into an uniform mass. Five grains contain one grain of opium.

PILLS, Opiate, formerly called *Thebaic pills*, of the Edinburgh Pharmacopeia, consist of one part of opium, seven parts of extract of liquorice, and two parts of pimenta berries; mixing the opium and extract, separately softened with diluted alcohol, and beating them into a pulp: then adding the Jamaica pepper rubbed to powder, and beating the whole into a mass. Ten grains contain one grain of opium.

PILLS, Storax, of the Dublin Pharmacopeia, are composed of three drams of purified storax, and soft purified opium and saffron, of each a dram; mix them well together by beating. Five grains contain one grain of opium. These preparations operate as anodyne; but the dose is different, and must be regulated by the quantity of opium contained in that which is adopted.

PILLS, Compound Squill, according to the London Pharmacopeia, are prepared by mixing together one dram of fresh squill-root (bulb) dried and powdered; ginger-root powdered, and hard soap, of each three drams, and two drams of ammoniacum powdered; and beating the mixed powders with the soap, adding as much syrup as will give them a proper consistence.

PILLS, Squill, of the Edinburgh Pharmacopeia, are prepared by beating one scruple of squill-root (bulb) dried and

and rubbed to a fine powder, ammoniacum, cardamom-seeds powdered, and extract of liquorice, one dram, with syrup, into a mass.

PILLS of Squill with Ginger, of the Dublin Pharmacopeia, are composed of a dram of powder of squill, two drams of ginger-root in powder, and ten drops of essential oil of aniseed, beaten together and formed into a mass with jelly of soap.

These pills are useful expectorants in chronic catarrh, dyspnoea, and asthma; and combined with calomel and digitalis in hydropic affections. As the efficacy of the squill is much injured by keeping in either form, it is perhaps better that it should be always given under the extemporaneous form, except when the tincture is used. The dose is from grs. x to ʒj, given three or four times a day. Thomson's London Dispensatory. London Pharmacopeia, 1809.

PILLS, Bechic, a sort of pills good against coughs, fo call from the Greek, βήχ, cough. They are also called *hypoglotides*, because left like lozenges to dissolve under the tongue.

PILLS de Cochia. See COCHIA.

PILLS of Colocynth with Aloes, Pilulæ colocynthide cum aloes, a name given in the late London Pharmacopeia to the purging pill, commonly known by the name of *pilule cochie minores*.

As this is originally a prescription of Galen, and the manner of proportioning the ingredients has been altered since his time; the College have ordered it to be made in this manner: take of colocynth, pulp sliced, six drams; extract of spike aloes, powdered, one ounce and a half; scammony gum-resin, powdered, half an ounce; cardamom-seeds, powdered, a dram; hard soap, three drams; and boiling water two pints. Macerate the colocynth pulp in the water for four days, in a gentle heat; strain the solution, and add to it the aloes, scammony, and soap; then, by means of a water bath, evaporate it to a proper consistence, constantly stirring, and about the end of the inspissation, mix in the cardamom-seeds. This is the "extractum colocynthidis compositum," P.L. 1787; "extractum catharticum," P.L. 1745; and "pilulæ Rudii," P.L. 1720. See COLOCYNTHIS.

Pilulæ colocynthide simpliciores, a name given in the late London Pharmacopeia to the purging-pill, commonly known by the name of *pil. ex duobus*. It is made of equal parts of colocynth and scammony, with a considerable proportion of oil of cloves; and is beat up to a consistence with syrup of buckthorn.

PILLS, Composing, are made by beating together ten grains of purified opium, and half a dram of Castile soap; the whole may be formed into twenty pills: and one, two, or three, may be taken as occasion requires, when a quieting draught will not fit upon the stomach.

PILLS, Fetid, are prepared by mixing half an ounce of assa foetida with any simple syrup. In hysterical complaints, four or five pills of an ordinary size may be taken twice or thrice a day. They will also be of service to persons afflicted with the asthma; and they may be made opening, if necessary, by adding a proper quantity of rhubarb, aloes, or jalap, to the above mass.

PILLS, Hemlock, are made by taking any quantity of the extract of hemlock, and adding to it about a fifth part its weight of the powder of the dried leaves, and forming it into pills. See CICUTA, in the *Materia Medica*.

PILLS for the Jaundice are prepared by taking of Castile soap, Socotorine aloes, and rhubarb, of each one dram, and making them into pills, with a sufficient quantity of syrup or mucilage. See JAUNDICE.

PILLS, Misfaubin's, a preparation of mercurius calcinatus (oxydum hydrargyri rubrum), supposed by Mr. Cavendish (Phil. Trans. vol. lxxiv. part i. p. 141.) to be the same with red precipitate, though differently prepared: these pills being disposed to occasion gripes, it has been usual to add a small quantity of opium, and some warm aromatic material. The dose is from half a grain to two grains; five or six grains are said to vomit and purge violently.

PILLS, Perpetual, or *Pilule perpetua*, are regulus of antimony made up in pills; thus called, because being swallowed and voided fifty times, they will purge every time with undiminished force. See ANTIMONY.

PILLS, Plummer's. See PLUMMER'S *Æthiops*, and **PILLS of Submuriate of Mercury**.

PILLS, Purging. See **PILLS of Aloes, Colocynth, &c.** supra.

Purging pills may be made of Socotorine aloes and Castile soap, of each two drams, and a sufficient quantity of simple syrup. Four or five of these will generally prove a sufficient purge. For keeping the body open, one may be taken night and morning. They are reckoned both deobstruent and stomachic, and will be found to answer all the purposes of Dr. Anderson's pills, the principal ingredient of which is aloes. When aloetic purges are improper, let pills be formed of extract of jalap, and vitriolated tartar, of each two drams, and a sufficient quantity of syrup of ginger; which may be taken as above.

PILL, Rudius's. See **EXTRACTUM Catharticum**, and **PILLS of Colocynth, &c.** supra.

PILLS, Soap, Pilule saponaceæ, a form of medicine prescribed in the late London Dispensatory, and ordered to be made in the following manner: take almond soap, four ounces; strained opium, half an ounce; essence of lemons, a dram; soften the opium a little with wine, and beat that and the soap with the essence, till it be reduced to the form of a pill. See OPIUM, and **PILLS of Soap, &c.** supra.

This is intended to supply the place of a pill commonly called *Matthew's pill*, and is very happily corrected in regard to the taste of the soap, by the addition of the essence of lemons.

PILLS, Stomachic, are made of extract of gentian, two drams; powdered rhubarb and vitriolated tartar, of each one dram; oil of mint, thirty drops: and a sufficient quantity of simple syrup. Three or four of these may be taken twice a day, for invigorating the stomach, and keeping the body gently open.

PILLS, Strengthening, are made of soft extract of the bark, and salt of steel, of each half an ounce. In disorders arising from excessive debility or relaxation of the solids, as the chlorosis, or green sickness, two of these pills may be taken three times a day.

PILL, Ward's. See **WARD'S Pill**.

PILLAGE, among *Builders*, is sometimes used for a square pillar, standing behind a column to bear up the arches; having a round base and capital, as a pillar has.

PILLAGE Bay, in *Geography*, a bay on the S. coast of Labrador. N. lat. 50° 17'. W. long. 62° 58'.

PILLAR, in *Architecture*, a kind of irregular column, round and insulate; but deviating from the proportions of a just column.

Pillars are always either too massive, or too slender, for a regular architecture. In effect, pillars are not restrained to any rules: their parts and proportions are arbitrary. Such, *e. gr.* are the pillars which support Saracenic vaults, and other buildings, &c.

A square pillar is a massive work, called also pier, or pierdroit,

piedroit, serving to support arches, &c. See **PIDR**, and **PIEDROIT**.

Butting-pillar is a butment, or body of masonry, raised to prop, or sustain, the thrust of a vault, arch, or other work. See **BUTRESS**.

It seems not impossible for stone to be cast into the shape of pillars. We find mention made in the Philosophical Transactions, of two pillars of stone at Fontevraud, in France, each about sixty feet high, all of one solid piece, which are said to have been run. (N^o 481. p. 328. in Not.) Pillars of stone were anciently erected, as sepulchral monuments, near the highways; and also in memory of some victory. We find traces of this custom in Cornwall and Wales, where these pillars are often found, and called *meinigwir*, a stone for play, perhaps in memory of funeral games; and sometimes *llech*, that is, *tabula faxea*. Phil. Transf. N^o 458. p. 471.

Pompey's pillar is a famous monument of antiquity, constructed of red granite, and situated on a rock, about a mile without the walls of Alexandria, in Egypt. By the mensuration of Edward Wortley Montagu, esq. the capital of the pillar, which is Corinthian, with palm leaves, and not indented, is nine feet seven inches high; the shaft sixty-six feet one and a quarter inch; the base five feet nine three quarter inches; the pedestal ten feet five and a half inches; the height from the ground ninety-two feet: though Dr. Pococke, by the shadow, determined the whole height to be one hundred and fourteen feet; and its diameter nine feet and an inch. It is perfectly well polished, and only a little shivered on the eastern side. Nothing can equal the majesty of this monument: seen from a distance, it over-tops the town, and serves as a signal for vessels. Approaching it near, it produces, says Savary, an astonishment mixed with awe. One can never be tired with admiring the beauty of the capital, the length of the shaft, nor the extraordinary simplicity of the pedestal. This prodigious mass stands, as on a pivot, on a reversed obelisk; and was erected, as many have supposed, either by Pompey, or to his honour. But as no mention is made of it by Strabo, Diodorus Siculus, or any other ancient writers, Mr. Montagu concludes that it was not known before the time of Vespasian, and that it was erected to his honour. In proof of this opinion, he found within the circumference of the pillar a medal of Vespasian in fine order.

Savary, on the authority of Abulfeda, who calls it "the pillar of Severus," ascribes it to this emperor; alleging that he visited Egypt, gave a senate to Alexandria, and delivered well of its inhabitants. Accordingly, it is said, that this column was a mark of their gratitude. The Greek inscription; half effaced, which is visible on the west side when the sun shines upon it, was legible, without doubt, in the time of Abulfeda, and preserved the name of Severus. Nor is this the only monument erected to him by the gratitude of the Alexandrians. In the midst of the ruins of Antinoe built by Adrian, is seen a magnificent pillar, the inscription on which is still remaining, dedicated to Alexander Severus.

Denon has given a drawing of this pillar, with the marked dimensions of its various parts: he makes its whole height a fraction more than 92 feet, and the height of the shaft, which is of a single piece, 63 feet 1.3. It acquired, as this author says, the name of Pompey's pillar in the 15th century. A monument, as he supposes, had been raised by Pompey at Alexandria, but it had disappeared, and was thought to be recovered in this pillar or column, which has since been converted into a trophy erected to the memory of Septimius Severus. It is, however, placed on the ruins of the ancient city; and in the time of Septimius Severus, the city of the

Ptolemies was not in a ruinous state. To support this column by a solid foundation, an obelisk has been sunk in the earth, on which is placed a very clumsy pedestal, having a fine shaft, and surmounted by a Corinthian capital of bad workmanship. If the shaft of this column, continues Denon, separating it from the pedestal and the capital, once belonged to an ancient edifice, it is an evidence of its magnificence, and of the skill with which it was executed. It ought, therefore, to be said, that what is called Pompey's pillar is a fine column, and not a fine monument; and that a column is not a monument. The earth about the foundation of this pillar having been cleared away by time, two fragments of an obelisk, of white marble, the only monument of that substance seen by Denon in Egypt, have been added to the original base, to render it more solid. After having observed that the column, entitled Pompey's pillar, is very chaste both in style and execution; that the pedestal and capital are not formed of the same granite as the shaft; that their workmanship is heavy, and appears to be merely a rough draft; and that the foundations, made up of fragments, indicate a modern construction; it may be concluded, says our author, that this monument is not antique; and that it may have been erected either in the time of the Greek emperors, or of the caliphs; since, if the capital and pedestal are well enough wrought to belong to the former of these periods, they are not so perfect but that art may have reached so far in the latter. See Pococke's Description of the East, vol. i. p. 8. and Phil. Transf. vol. lvii. art. 42. Savary's Letters in Egypt, vol. i. Denon's Travels in Egypt, vol. i.

PILLAR, in the *Manege*, signifies the centre of the volta, ring, or manege ground, round which a horse turns, whether there be a wooden pillar in it or not.

There are also pillars in maneges on the circumference, or side, placed at certain distances, by two and two. To distinguish these from that of the centre, they are called the *two pillars*. When these latter are spoken of, it is usual to say, *Work the horse between the two pillars*. When the former, it is called, *Working round the pillar*. The use of the pillar in the centre is for regulating the extent of the ground, that the manege upon the volts may be performed with method and justice, and that they may work in a square, by rule and measure, upon the four lines of the volts; and also to break unruly high-mettled horses, without endangering the rider.

The two pillars are placed at the distance of two or three paces one from the other. The horse is put between these, to teach him to rise before, and yerk out behind, and put himself upon raised airs, &c. either by the aids, or chastisement.

It has been supposed, that the hint of using pillars in the manege was taken from a contrivance of Eumenes; who, as Plutarch relates it, being besieged at the fort of Nora, by Antigonus, and fearing lest his horses should suffer for want of action, contrived a method of working them, without removing them from their stalls. For this purpose he placed a pulley over their heads in the beams of the stables, with which, by means of running reins, he pulled up their fore-parts, causing at the same time people to stand behind them, who, urging and lashing them with whips, put them into motion, made them yerk out behind, raising and moving their fore-legs, and work and chafe themselves till they sweat copiously; by these means he preserved their health, kept them in wind, and ready for service. The single pillar, once so frequent in maneges, but now laid aside, was first used in Naples, and owes its origin to the want of covered buildings for siding and breaking horses: in lieu of which they

they dug trenches for working their horses; the sides of the trenches supplying the want of walls, and producing in a certain degree the same effect. The famous Pignatelli, of Naples, having no covered manege, worked his horses in the open air, and used to tie them to a tree, and work them round it. Pluvial, of France, was one of his scholars; and returning to France, where he professed horsemanship, he placed a post or pillar in his manege, in imitation of Pignatelli's tree, and made the same use of it: to this he soon added another of the same size and height; which two pillars were calculated to answer purposes different from those for which the single pillar had been erected: the two pillars are still in use, and reckoned an essential piece of furniture in all riding-houses. The single pillar has been long discontinued, but may be employed to advantage upon certain occasions; especially where a horseman undertakes to *longe* a horse, without the assistance of another person. It should be observed that no horse ought to be put between the two pillars till he is well supplied; and has acquired the first principles of the union between the legs, which are the natural pillars that every horseman should employ. The horse should be gently worked at first, that he may not become furious, and he should be made to go only from side to side by means of the switch, or from fear of the chambriere. In a few days, when he is accustomed to the subjection of the pillars, try to make him insensibly go into the cords, and endeavour to get from him a step or two exact, and in time of the *passage* or *piasser*.

The worst effect of the pillars is the hazard you run of entirely ruining the hocks of your horse; if you do not distinguish very exactly between these parts and the haunches. Berenger's *Hist. and Art. of Horsemanship*, vol. ii. p. 60. and 164, &c.

PILLAR, Cape, in *Geography*, a cape at the western entrance of the straits of Magellan, which is known by a large gap upon the top; and when it bears W.S.W. an island appears off it which has an appearance somewhat like a hay-stack, and about which lie several rocks. The strait to the eastward of the cape is between seven and eight leagues over; the land on each side is of a moderate height, but it is lowest on the north shore, the south shore being much the boldest, though both are craggy and broken. Westminster island is nearer to the north than the south shore; and by the compass lies N.E. from cape Pillar. S. lat. 52° 45'. W. long. 75° 10'.

PILLARS, in *Ship Building*, are square or round columns of timber, fixed perpendicularly under the middle of the beams for the support of the decks.

PILLARS, Ropes of two. See **ROPE**.

PILLAU, in *Geography*, a sea-port town of Prussia, in the province of Samland, situated on a tongue of land that projects into the Baltic, at the entrance of the Frisch Haff, with a good harbour; well fortified, and considered as the bulwark and key of the kingdom. The streets are broad and straight; and the houses are built and furnished in the Dutch taste. This harbour is frequented by foreign ships, and the town is the resort of people of various nations. The fort is nearly a regular pentagon; the bastions exhibit a grand appearance; and all the edifices belonging to the fortifications are strong, handsome, and regular. Here is also a magazine for military stores. In the fort there is a church, serving for both the Lutherans and Calvinists, and below the gate of the castle is a stone equestrian statue of Frederic William the Great. Over the gate, on one side of the entrance, stands the image of Mars, in a bold attitude, looking towards Sweden. The peninsula along

which the road from Pillau to Fischhausen lies, is called the "Paradise of Prussia," from its pleasantness and fertility. Near the fort is a fine plain, where the Frisch Haff forms a fine semicircular bay, that is frequented by a great number of swans, sea-mews, wild-ducks, and other water-fowl. On the other side of the bay lies Alt Pillau or Old Pillau, inhabited by fishermen; 22 miles W.S.W. of Königsberg. N. lat. 54° 37'. E. long. 19° 55'.

PILLE of *Foddray*, or **PILE Fouldery**, in the county of Lancaster; a defence built on a creek of the sea, called *Pille*, by the idiom of the county, for a pile, or a fort, built for the safeguard or protection of any place.

This pile was erected there by the abbot of Fournesse, in the first year of Edward III. *Camd. Brit. Rex.* "Dedimus Henrico comiti Northum. insulam, castrum, pelam, & dominium de Man, &c." *Rot. Par.* 1 Hen. IV.

PILLEER, in *Geography*, a town of Hindoostan, in Mysore; nine miles N.W. of Dalmachery.

PILLERSTORFF, a town of Austria, on the river Rusbach; eight miles E.N.E. of Korn-Neuberg.

PILLIBeat, a town of Hindoostan, in Rohilcund; 28 miles N.E. of Bereilly. N. lat. 28° 36'. E. long. 80° 10'.

PILLORY was anciently a post erected in a cross road, by the lord, as a mark of his feigniory, with his arms on it, and sometimes with a collar to tie criminals to.

PILLORY, at present, is a wooden machine, on which certain criminals, as perjurers, &c. are fastened, and exposed to the public derision.

With us it is in the form of a frame erected on a pillar, and made with holes and folding boards, through which the heads and hands of criminals are put.

The etymology of this word has been variously assigned by different writers: Spelman derives it from the French *pilleur, depeculator*; Cowel from *πύλος, janua*, and *οραω, video*; but the etymology of Du-Cange is the most probable, who derives it from *pila, a pillar*.

In the laws of Canutus it is called *bealþchang*. Sir Henry Spelman says it is *supplicii machina ad ludibrium, magis quam penam*. It was peculiarly intended for the punishment of bakers who should be caught faulty in the weight, or fineness, of their bread. In old charters it is called *collistrigium*.

The pillory in Paris is in the middle of a round tower, with openings on every side. It is moveable on an axis, or arbor; round which the executioner gives the criminal the number of turns appointed in court; stopping him at each opening, to shew him to the people. It was intended for several kinds of criminals, particularly for fraudulent bankrupts; and all those who made a cession, or surrender, of their effects to their creditors, were obliged to take some turns round the pillory on foot, with a green cap on.

PILLOW of a *Plough*, a term used by the farmers to express that part of a plough which serves to raise or sink the beam, and with it the share, as the land is to be ploughed shallower or deeper.

This pillow is a cross piece of wood, reaching from one of the crow-staves, or uprights, to the other; and as they are bored with two rows of holes, this pillow can be slipped up or down to any height, and kept there by pegs or cords in the holes. See **PLOUGH**.

PILLOW, in a *Ship*, is that piece of timber whereon the bowsprit rests at its coming out of the hull aloft, close by the stem.

PILLVENKEGEN, in *Ornithology*, the name of a bird approaching to the snipe kind; described by Aldrovand, and supposed by some to be the bird we call the *knot*.

PILNAUD, in *Geography*. See **PALNAUD**.

PILNIKAW, a town of Bohemia, in the circle of Königgratz; five miles W.S.W. of Trautenau.

PILNITZ, a town of Saxony, in the margraviate of Meissen, seated on the Elbe, in which is a royal palace; celebrated for a treaty entered into by the powers of Europe against France in 1792; seven miles S.E. of Dresden.

PILOBOLUS, in *Botany*, from *πῖλος*, a cap or cover, and *βολος*, a throw, or cast. Tode Fung. Mecklenb. fasc. 1. 41. Perf. Syn. 117.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Receptacle stalk-like, pellucid, bearing a naked vesicle, which flies off elastically.

1. *P. crystallinus*. Perf. Obs. Mycolog. v. 1. 76—78. t. 4. f. 9—11. Fl. Dan. t. 1080. (*Mucor urceolatus*; Dickf. Crypt. fasc. 1. 25. t. 3. f. 6. Bull. Fung. t. 480. f. 1.)—Receptacle obovate. Vesicle hemispherical, black.—Common in autumn on horse or cow-dung. In an early state it appears, according to the observations of Persoon, like some little yellowish kind of *Sphæria*; but it soon becomes an obovate, stalked, pellucid, whitish body, about half an inch high, full of a clear watery liquor, and bearing on its top a black hemispherical head, of short duration.

2. *P. roridus*. Perf. n. 2. (*Mucor roridus*; Bolt. Fung. t. 132. f. 4. Relh. Cant. 548?)—Receptacle globose, with a capillary stalk. Vesicle depressed, black.—Found by Bolton on horse-dung, in fields about Halifax, in August and September, when the morning is cloudy, as it perishes when the sun shines upon it. The plants are four lines high, growing in clusters, and distinguished from the former by the long slender stalk, globose head, and minute, depressed, black vesicle.

PILOCARPUS, from *πῖλος*, a cover, and *καρπος*, fruit. Vahl Eclog. v. 1. 29. Willd. Sp. Pl. v. 1. 1133. Mart. Mill. Dict. v. 3.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumose*, Linn. *Rhamnii*, Juss.

Eff. Ch. Calyx of five leaves. Petals five. Stamens inserted under the germin. Capsules five, combined at the base, elastic. Seeds solitary, tunicated.

1. *P. racemosus*. Vahl t. 10. (*Euonymus latifolius racemosus*, fructu pentagono atropurpureo; Plum. Ic. 119. t. 127.)—Native of lofty mountains in the island of Montserrat. A low shrub, with pendulous branches. Leaves alternate, on short stalks, elliptical, entire, very obtuse, and generally emarginate. Clusters terminal, solitary, many-flowered, a foot or more in length. We readily agree with Willdenow that this plant is very nearly akin to *Euonymus*; certainly far more so than to *Prunus*, to which Burmann, the editor of Plumier, refers it!

PILORUS, in *Ancient Geography*, a town of Macedonia, situated at the foot of mount Athos, or rather on the Singitic gulf, S.W. of Asia.

PILOSE LEAF, in *Botany*. See LEAF.

PILOSELLA, diminutive of *pilosa*, hairy, an old appellation, and now the Linnæan specific name, of a very common species of *Hieracium*, remarkable for the long tawny hairs of its leaves.

PILOT, the person who superintends the navigation of a ship, either upon the sea-coast, or on the main ocean; but it is more particularly applied to a person retained on board a ship to conduct it into a road or harbour, or over bars or sands; or through serpentine and intricate channels, or the like.

Menage derives the word pilot from *prorita*; *q. d.* he who governs the prow, or head. Others fetch it from the old French *pîle*, a ship.

Pilots are no constant and standing officers on board our vessels; but are mostly called in occasionally, on coasts and

shores unknown to the master. And, having done their parts in piloting the vessel, they return to shore, where they reside.

The regulations, with regard to pilots in the royal navy, are as follow: the commanders of the king's ships, in order to give all reasonable encouragement to so useful a body of men as pilots, and to remove all their objections to his majesty's service, are strictly charged to treat them with good usage, and in equal respect with warrant-officers.

The purser of the ship is always to have a set of bedding provided on board for the pilots, and the captain is to order the boatswain to supply them with hammocks, and a convenient place to lie in, near their duty, and apart from the common men; which bedding and hammocks are to be returned when the pilots leave the ship.

A pilot, when conducting one of his majesty's ships in pilot-water, shall have the sole charge and command of the ship, and may give orders for steering; setting, trimming, or furling the sails; tacking the ship; or whatever concerns the navigation: and the captain is to take care that all the officers and crew obey his orders. But the captain is diligently to observe the conduct of the pilot, and if he judges him to behave so ill as to bring the ship into danger, he may remove him from the command and charge of the ship, and take such methods for her preservation as shall be judged necessary; remarking upon the log-book the exact hour and time when the pilot was removed from his office, and the reasons assigned for it.

Captains of the king's ships, employing pilots in foreign parts of his majesty's dominions, shall, after performance of the service, give a certificate thereof to the pilot, which being produced to the proper naval officer, he shall cause the same to be immediately paid; but if there be no naval officer there, the captain of his majesty's ship shall pay him, and send the proper vouchers, with his bill, to the navy-board, in order to be paid as bills of exchange.

Captains of his majesty's ships, employing foreign pilots, to carry the ships they command into or out of foreign ports, shall pay them the rates due by the establishment or custom of the country, before they discharge them; whose receipts being duly vouched, and sent with a certificate of the service performed, to the navy-board, they shall cause them to be paid with the same exactness as they do bills of exchange. Regulations and Instructions of the Sea Service, &c.

Pilots of ships taking upon them to conduct any ship from Dover, &c. to any place up the river Thames, are to be first examined and proved by the master and wardens of the Trinity-house, &c. or shall forfeit 10*l.* for the first offence, 20*l.* for the second, and 40*l.* for every other offence; one moiety to the informer, the other to the master and wardens; but any master or mate of a ship may pilot his own vessel up the river: and if any ship be lost through the negligence of any pilot, he shall be for ever afterwards disabled to act as a pilot. (3 Geo. I. cap. 13.) The lord wardens of the cinque-ports may also make rules for the government of pilots, and order a sufficient number to ply at sea to conduct ships up the Thames. 7 Geo. I. cap. 21.

No person shall act as a pilot on the Thames, &c. (except in collier ships) without licence from the master and wardens of the Trinity-house, at Deptford, on pain of forfeiting 20*l.* Pilots are to be subject to the government of that corporation, and pay ancient dues not exceeding 1*l.* in the pound out of wages for the use of the poor thereof. (5 Geo. II. cap. 20.) In charter parties of affreightment, the master generally covenants to find a pilot, and the merchant to pay him; and in case the ship shall miscarry through

the insufficiency of the pilot, the merchant may charge either the master or the pilot; and if he charges the master, such master must have his remedy against the pilot. *Lex Mercator.* 70.

Among the French, pilot is also used for a steersman, or an officer on board a ship, who always watches her course, and directs it.

There are among the French two kinds of pilots; the one a coasting pilot, well acquainted with the coasts, ports, roads, bars, sands, &c., and who commands in sight thereof.

The other an officer who makes observations, and takes altitudes out at sea; uses the quadrant and fore-staff; and also watches the compass.

The pilot is always the second person in the ship, whether it be a man of war, or merchant-man. In the former the captain is the first, the pilot the second. In a merchant-ship, the master is the first, the pilot after him.

The pilot is also the steersman, who stands at the helm, and manages the rudder.

PILOTAGE, money paid for piloting a ship.

PILOTING, in *Navigation*, is either common or proper: common piloting is that art which consists in coasting along shore, or sailing within sight of land. Proper piloting is the art of sailing to distant places through the ocean, and out of sight of land. See *NAVIGATION*, *PILOT*, and *SAILING*.

PILOTO, or *Salinas del Piloto*, in *Geography*, craggy rocks on the W. coast of Mexico, S.E. of Cape Corientes, where are good anchorage, and shelter from N.W. and W. and S.W. winds, and near which are salt-pits.

PILOT-TOWN, a town of America, in Suffex county, Delaware; six miles N.W. of Cape Healopen.

PILOUTA, a town of Candahar, on the Attock; 90 miles N.N.W. of Moultan.

PILOUTAI HOTUN, a town of Chinese Tartary, near the river Hoang-ho; 305 miles W. of Peking. N. lat. 40° 38'. E. long. 108° 43'.

PILPAY, or *BIDPAY*, in *Biography*, an oriental philosopher, of whose country, time, life, or works, little is known with any degree of certainty. According to tradition he was the counsellor and vizier to an ancient king of India, for whose use he composed his famous apologues or fables. These apologues are in the form of dialogues between two animals of a species very like the European fox. The fame of this work having reached Persia, Chosroes, the king of that country, is said to have sent his physician into India for the sole purpose of procuring a copy of it. This physician, being permitted to peruse it in the library of the Indian king, translated it into the ancient Persian, and gave it the title of the *royal or august book*. Such is the account given of Pilpay, and of the introduction of his fables into Persia. The work itself is thought to contain internal evidence of its having been written at a much later period. It has been translated into most of the modern languages; but the best European version is the French one of M. Galland, published in two vols. 12mo. 1714, with relics of the fables of Lokman. The same writer published the translation of another work attributed to Pilpay, entitled "The Shipwreck of the floating Islands, or the Basiliad." *Enfield's Hist. Phil.*

PILSEN, in *Geography*, a town of Hungary, on the river Ipol; 10 miles N.E. of Gran.—Also, a well-built and fortified town of Bohemia, and capital of a circle of the same name, situated near the conflux of the rivers Miza and Radbuzo. The circle is rich in sheep; and the cheese made by the inhabitants is preferred to any other in the kingdom;

44 miles S.W. of Prague. N. lat. 49° 43'. E. long. 13° 33'.

PILSENITZ, a town of Bohemia, in the circle of Pilsen; five miles S.E. of Pilsen.

PILSNO, a town of Austrian Poland; 56 miles S.W. of Sandomirz.

PILSTART. See *PYLSTART*.

PILSTING, a town of Bavaria; two miles N. of Landau.

PILTEN, a town of the duchy of Courland, and capital of a district, anciently called "the diocese of Courland;" 12 miles N.N.W. of Goldingen. N. lat. 57° 5'. E. long. 21° 38'.

PILTEX Lake, a lake of Chinese Tartary, 23 miles in circumference; 25 miles S.W. of Nimgouta.

PILULARIA, in *Botany, from *pilula*, a little ball, or pill, in allusion to the shape of its receptacles.—*Linn. Gen.* 561. *Schreb.* 754. *Mart. Mill. Dict.* v. 3. *Sm. Fl. Brit.* 1143. *Juss.* 16. *Lamarck Illustr.* t. 862. — Class and order, *Cryptogamia Filices*, or perhaps *Monoclea Polyanthra*. *Nat. Ord. Filices*, *Linn. Juss.**

Ess. Ch. Common receptacle globose, of four cells and four valves, filled with numerous anthers in the upper part, and numerous pistils in the lower. Seeds coated.

1. *P. globulifera*. *Pillwort*. *Linn. Sp. Pl.* 1563. *Engl. Bot.* t. 521. *Bolt. Fil.* 72. t. 40. *Fl. Dan.* t. 223. *Bulliard* t. 375. (*P. palustris juncifolia*; *Vaill. Par.* t. 15. f. 6. *Dill. Musc.* 538. t. 79. *Pepper-grass*; *Pet. Herb. Brit.* t. 9. f. 8.)—This, the only known species of its genus, is found on heaths that are partially inundated, in various parts of England, France, and Germany, flowering in June and July. The thread-like *stem* creeps close to the ground, with fibrous *roots* supposed to be perennial, and throws up many erect, scattered or clustered, awl-shaped, smooth, simple branches, two or three inches high, each of which unrolls, in the peculiar manner of genuine ferns, or of some intermediate plants between ferns and palms, as the *Cycas* and *Zamia*, to which, however widely different in dimensions, the *Pilularia* is perhaps most allied. Its little blackish globular *fruits*, or *receptacles*, resembling pepper-corns, are solitary, and nearly sessile, at the bases of the branches, and are externally downy. *Bulliard's* figure is excellent.

PILUM, in *Roman Antiquity*, a massive weapon, which in charge they darted upon the enemy. It was commonly four-square, but sometimes round, composed of a piece of wood three cubits long, and a slip of iron of the same length, hooked and jagged at the end.

PILWARA, in *Geography*, a town of Hindoostan, in Oudipour; 40 miles N. of Oudipour. N. lat. 25° 19'. E. long. 74° 25'.

PILY BARRY. See *BARRY Pily*.

PILZICHE, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 10 miles S.E. of Schwarzenberg.

PIMBLE-MERE. See *BALA POOL*.

PIMELA, in *Botany, from *πιμελον*, *fatness*, because of the oily nature of its nut, a genus of *Lourciero's*, *Cochinch.* 407. See *CANARIUM*.*

PIMELÆA, a name adopted, by the writer of this, from the manuscripts of the celebrated Solander, and derived from *πιμελον*, *fatness*; in allusion, as it is supposed, to the oiliness of its little oval seed, like an olive in miniature. As there is a Fabrician genus of insects named *Pimelia*, from their corpulent shape, we wish to include the idea of an olive, *ελαια*, in the above word; writing it therefore with a diphthong, to guard against ambiguity, either in its sense or pronunciation.—*Sm. Bot. of New Holl.* 31. *Mart. Mill. Dict.* v. 3. *Willd. Sp. Pl.* v. 1. 50. *Vahl. Enum.*

PIMELÆA.

v. 1. 305. Brown Prodr. Nov. Holl. v. 1. 359. Ait. Hort. Kew. v. 1. 25. Lamarck Illustr. t. 9. (Bankia; Forst. Gen. t. 4.)—Class and order, *Diandria Monogynia*. Nat. Ord. *Veprecula*, Linn. *Thymelæa*, Juss. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, funnel-shaped, coloured; tube thread-shaped, very long; limb spreading, in four deep segments, two opposite ones exterior; mouth naked and pervious. *Cor.* none. *Stam.* Filaments two, capillary, inserted into the mouth of the tube, opposite to the outer segments (*Brown*); anthers roundish, erect, simple, of two cells. *Pist.* Germen ovate, superior; style thread-shaped, as long as the tube, inserted laterally into the germen; style capitate, small, smooth. *Peric.* a dry, or slightly succulent, berry, with a thin coat. *Seed* solitary, ovate, obliquely pointed.

Ess. Ch. Calyx funnel-shaped, four-cleft, coloured, withering. Petals none. Stamens prominent, inserted into the top of the tube. Style lateral. Stigma capitate, smooth. Seed coated.

Obf. This genus comes nearest in technical characters to *Passerina*, from which it differs nevertheless sufficiently, in having but two stamens instead of eight, and, if we mistake not, a constantly smooth stigma, instead of a hispid one. (See *PASSERINA*, *GNIDIA*, and *DAPHNE*, for remarks on the generic characters of this tribe.) Forster originally called the genus before us *Bankia*; but its species having all been reduced, by Linnæus and his son, to *Passerina*, a much finer genus was fortunately chosen to commemorate our illustrious countryman, and the name which he and his friend Dr. Solander had first contrived for this, is now retained. Of its numerous species we know not how to give any thing more than a comprehensive idea, nor can we calculate their number with perfect precision. Willdenow has only four, consisting of our *linifolia*, first published in the Botany of New Holland, and the three Forsterian *Bankiæ*, given as *Passerina* in Linn. Suppl. 226, 227. Vahl has added two. Labillardiere describes six more, from the south coast of New Holland. But Mr. Brown has carried our knowledge of this genus far beyond any preceding writer, as he defines thirty-four species of *Pimelæa* from New Holland alone. In these are not included the above three plants of Forster, nor the *virgata* of Vahl, being natives of New Zealand only; from which country we are possessed of three others, given by sir Joseph Banks to the younger Linnæus, and hitherto, we believe, entirely nondescript. Thus the known species may be reckoned to amount to forty-one. Of these *linifolia* alone is mentioned in the Hortus Kewensis, as cultivated in Britain. Mr. Brown divides this genus into five sections, of which we shall give examples.

SECT. 1. *Leaves opposite. Flowers in a terminal lead. Involucrum (or rather four bractæas) unlike the leaves.* Fourteen species.

P. cornucopiæ. Vahl. n. 1. Br. n. 1.—Common bractea of one leaf, funnel-shaped, with four broad acute segments. Stem herbaceous.—Gathered by sir Joseph Banks at New South Wales, in 1770. Mr. Brown has met with the same in the tropical part of New Holland. This is one of the very few herbaceous species, most of the genus being shrubby, with the habit of *Daphne* and *Passerina*. Every part is smooth. *Branches* slender. *Leaves* an inch long, more or less, elliptic-lanceolate, entire as in all the rest of this natural order, of a fine green, minutely dotted. *Flowers* small, greenish-yellow, with a reddish slender tube about half an inch long. *Stamens* about the length of the rather unequal limb. The head of *flowers* is encompassed with four broad, acute, green *bractæas*, about its own length,

the two outermost heart-shaped at the bottom, and all connected by an inversely conical basis, of one leaf, resembling a *cornucopiæ*.

P. linifolia. Flax-leaved *Pimelæa*. Sm. Bot. of New Holl. 31. t. 11. Willd. n. 1. Br. n. 4. Vahl n. 2. Curt. Mag. t. 891.—*Bractæas* ovate, broad, smooth on both sides, half the length of the head. Tube of the calyx silky. Leaves linear-lanceolate, or partly spatulate, stalked, single-ribbed.—Native of New South Wales and the island of Van Diemen. *Br.* In England it is a green-house shrub, bearing, from February to August, a profusion of elegant, white, but inodorous, *flowers*. The copious straight *branches* are clothed with numerous, smooth *leaves*, about an inch long, variable in breadth. The globular brittle common *receptacle* remains long after the *flowers* and *seeds* are fallen, surmounted by numerous young flowering branches.

SECT. 2. *Leaves opposite. Head terminal. Bractæas scarcely different from the leaves.* Fifteen species in Mr. Brown's Prodrum; to which are to be added the New Zealand species, all of them, as far as we have seen, answering to the character of this section.

P. drupacea. Labill. Nov. Holl. v. 1. 10. t. 7. Br. n. 27.—Leaves oval-oblong, flat, slightly downy beneath; floral ones longer than the head. Tube of the calyx cylindrical, deciduous. Fruit pulpy.—From Van Diemen's land. Above six feet high. Young *branches* hairy. *Leaves* about an inch and a half long; the floral ones two or four, sometimes larger, sometimes smaller, than the rest. Besides the usual terminal head of *flowers*, there are several small, opposite, axillary ones, with two diminutive floral leaves to each. *Stamens* half the length of the limb. *Berry* black, pulpy.

P. longifolia. Banks, Herb. Linn. fil.—Leaves lanceolate, acute, smooth on both sides; floral ones twice as long as the many-flowered head. Calyx externally silky.—Gathered by sir J. Banks at New Zealand, in 1769. This seems to be a tall and handsome *shrub*, smooth in every part except the *flowers*, which are white, externally silky, with elliptical obtuse segments. *Leaves* willow-like, three inches long, half an inch wide, on short broad *footstalks*; the floral ones four, half the size of the rest, but full twice the length of the flowers.

P. lævigata. (*P. lævigata* β ; *ibid.*)—Leaves ovate, obtuse, concave, smooth on both sides; floral ones the length of the head. Calyx and young branches silky.—From the same country. *Stem* apparently procumbent. Young *branches* numerous, clothed with fine, dense, rather prominent, white, silky hairs. *Leaves* scarcely above a quarter of an inch long, perfectly smooth and naked; the floral ones exactly like the rest. *Flowers* many in each head, the length of the leaves, externally finely silky; their segments broad and rounded.

P. villosa. *Ibid.*—Leaves imbricated, ovate, acute, concave; smooth above; very hairy beneath; floral ones the length of the head. Calyx and young branches hairy.—From the same country. This agrees with the last in size, but seems more erect, and differs in the long shaggy, though shining, pubescence of the *flowers*, young *branches*, and backs of the *leaves*.

P. prostrata. Vahl n. 6. (*P. lævigata* α ; Banks, H. Linn. fil. *Bankia* prostrata; Forst. Gen. t. 4. f. k—n. *Passerina* prostrata; Linn. Suppl. 227. Forst. Prodr. 28.)—Leaves elliptical, obtuse, concave, smooth on both sides; floral ones the length of the head. Calyx and young branches hairy.—Native of dry hills in New Zealand. Very like the last but one, though smaller in all its parts, with elliptical

elliptical rather than ovate *leaves*, fewer *flowers* in each head, and slightly hairy, rather than densely silky, young *branches*, as well as *calyx*. It is still possible this and *Levigata* may be varieties of each other, as their original discoverers thought.

P. pilosa. Vahl. n. 4. (*Bankfia tomentosa*; Forst. Gen. n. 2. *Passerina pilosa*; Linn. Suppl. 226. Forst. Prodr. 28.)—Leaves lanceolate, obtuse, hairy beneath; floral ones rather ovate, twice the length of the few, lateral or terminal, hairy flowers.—Found in New Zealand.—*Stem* erect, woody. *Branches* repeatedly forked, short, spreading, silky. *Leaves* about an inch long; losing their hairs by age.

P. Gnidia. Vahl n. 3. (*Bankfia Gnidia*; Forst. Gen. t. 4. f. a.—*i*. *Passerina Gnidia*; Linn. Suppl. 226. Forst. Prodr. 28.)—Leaves ovato-lanceolate, acute, stalked, rigid, channelled, quite smooth, as well as the branches. *Calyx* very hairy.—Found in the fissures of rocks in New Zealand, near the coast, as well as on the loftiest mountains. The copious bright-green *leaves*, about an inch long, have the aspect of myrtle. The floral ones rather exceed in length the dense heads of copious white *flowers*, whose outside is very hairy.

SECT. 3. *Leaves opposite. Flowers spiked.* One species only.

P. spicata. Br. n. 30.—Leaves oval, smooth, as well as the calyx. Spikes naked. Flowers polygamous. *Br.*—Found near Port Jackson, New South Wales. This is a delicate, smooth, upright species, whose *leaves* have the aspect of some *Hypericum* or *Euphorbia*. The *flowers* are of a yellowish-green, tipped with purple, and are remarkable for forming a simple corymbose smooth *spike*, at the summit of each branch. The segments of the *calyx* are broad and obtuse; tube very slender, quite smooth.

SECT. 4. *Leaves opposite. Flowers axillary.* One species.

P. argentea. Br. n. 31.—“Leaves lanceolate, silvery on both sides. Flowers from two to four together, axillary.”—Gathered by Mr. Brown on the south coast of New Holland. We have seen no specimen.

SECT. 5. *Leaves alternate.* Three species.

P. curviflora. Br. n. 32.—Leaves elliptic-oblong; smooth above; somewhat silky beneath, like the branches, with depressed hairs. Heads lateral, of few flowers. *Calyx* silky; tube curved; limb unequal.—Native of Port Jackson. We have fine specimens from Sir J. Banks. This is a humble shrubby species, with thyme-like scattered *leaves*. The dried *flowers* are of a dull greenish-brown; their tube externally very silky; segments of the limb acute, one of them rather longer than the rest.

P. gracilis. Br. n. 33.—“Leaves oblong-linear, taper at the base; rather hairy beneath; some of them opposite on the branches. Heads lateral and terminal, of few flowers. *Calyx* silky; tube nearly straight; limb equal.”—Gathered by Mr. Brown in the south part of New Holland.

P. latifolia. Br. n. 34.—“Leaves oblong; acute and hairy at the base; rather silky beneath. Heads many-flowered, spiked; either terminal and sessile; or stalked and opposite to the leaves. *Calyx* villous.”—Found by Mr. Brown in the tropical region of New Holland. We have seen neither of these two last species.

PIMELIA, in *Entomology*, a genus of the Coleoptera order of insects. The generic character is as follows: antennæ filiform; four feelers; thorax plano-convex, margined head exerted; shells rather rigid; they are seldom found with wings. There are nearly 120 species enumerated by Gmelin, divided into sections, according as their

antennæ are moniliform, or entirely filiform; and these are subdivided according to the shape and structure of the feelers.

A. *Antennæ moniliform at the tip.*

a. *Feelers filiform.*

Species.

STRIATA. Black, glabrous; shells with four fanguineous striæ. It is a native of India. The body is gibbous; antennæ brown at the tip; shells united, the four streaks meeting at the tip.

UNICOLOR. Glabrous, black; the shells are marked with three raised obsolete lines. This is called the *Tenebrio gibbus* by Pallas. It is found at the Cape of Good Hope; as is the next.

FLAVICOLLIS. Glabrous, black; head white, villous behind.

GIBBA. Black; thorax globular; shells with an abbreviated lateral line. It is a native of India.

GLOBOSA. Thorax globular and very smooth; the shells are spinous behind. This is a native of the Cape.

LÆVIGATA. Oblong, black; thorax globular; shells very smooth, immaculate. It inhabits Hungary.

GLABRATA. Ovate, black; thorax globular; shells very smooth, immaculate. This is found in divers parts of Germany.

HISPIDA. Dull black; body rough, with erect stiff hairs. It inhabits Alexandria.

LONGIPES. Black; shells united, muricate; the legs are long. It is a native of several parts of Egypt.

RUSTICA. Thorax globular; grey; shells with a single raised angular line. It inhabits the Cape of Good Hope.

MURICATA. Black; shells obtuse, with muricate striæ. It inhabits southern Europe and the East.

TUBERCULATA. Black; thorax rough; shells with sub-spinous tubercles. It inhabits divers parts of Italy.

VARIOLOSA. Black; thorax smooth; shells with obtuse tubercles; the legs are long. It inhabits the Cape.

BI-PUNCTATA. Black; thorax globular, with two impressed dots; the shells are rugged, with three raised smooth striæ. This is a native of Italy.

SCABRA. Black; shells rough; the antennæ and legs are brown. This is found at the Cape.

GROSSA. Black; shells rough, with three smooth raised lines. It inhabits Barbary.

ANGULATA. Shells spinous, with a lateral raised ferrate line. It is a native of Alexandria.

ECHINATA. Thorax spinous at the sides; shells with raised spinous lines. It inhabits the Cape of Good Hope.

DENTATA. Thorax glabrous; body black; shells brown, with three raised ferrate lines. It inhabits the Cape.

PORCATA. Thorax smooth, polished; shells with three raised lines, the spaces between are rough, with raised dots.

MACULATA. Thorax black; shells cinereous, spotted with brown, with three raised lines; the second slightly waved. It inhabits the Cape.

SERRATA. Thorax variegated, shells with three raised lines; the interstices are rugged, and the legs long.

MINUTA. Thorax smooth and dusky; the shells are cinereous and rough, with three raised smooth lines.

RUGOSA. The thorax of this species rough; the shells are rugged, and narrower before.

SPINOSA. Thorax margined, spinous before and behind; the

PIMELIA.

the shells are marked with raised smooth striæ. It is found in the south of Europe, and also in the East.

ACUMINATA. Thorax margined, the fore and hind margins are spinous; the shells are smooth and united. A native of southern Europe.

REFLEXA. Thorax margined, and reflected at the edges; the shells are muricate, with a single raised lateral line. Found in the East.

FASCIATA. Of this the thorax is sub-orbicular: the body is black; and the shells have two abbreviated yellow bands. It is an Indian insect.

COLLARIS. Black; shells smooth, with a single angle; the thorax is narrower than the shells; the head is depressed, carinate. Found in the southern parts of Europe.

CARINATA. Black; thorax orbicular; shells raised with three smooth lines. Inhabits the south of Europe.

CILIATA. Black; depressed; thorax and shells ciliate, the latter reflected at the edges. It is a native of the Cape.

LINEATA. Rounded and rough thorax; the shells have three lines of raised dots, and between these there are three lines. It inhabits Siberia.

LEUCOGRAPHA. Rounded and rough thorax; shells cinereous, with nine black raised lines. It is a small insect, and found in Saxony.

GLABRA. Black; thorax rounded and smooth; the shells are very smooth. It inhabits Egypt, and varies very much in size.

ANGUSTATA. Glabrous; thorax narrowed behind; shells pointed. It inhabits the East. The body is entirely shining black.

ORBICULATA. Glabrous; thorax orbicular; shells pointed. It is denominated the *Tenebrio nomas* by Pallas. It is a native of the East.

CEPHALOTES. Thorax ciliate at the fore and hind edges; the shells are very rough, with four raised lines, the lateral ones carinate and subferrate. It inhabits the deserts of Ural.

CONVEXA. Black, smooth; thorax orbicular, convex, truncate before. It is found in divers parts of Europe and Africa.

LINEARIS. Black, smooth; legs ferruginous; antennæ very short. It inhabits Sweden.

PUBESCENS. Ovate, pubescent, opaque; shells with each four denticulate ribs. It is found in Egypt.

AURITA. Thorax margined, dilated on the fore part; shells bicarinate, with two gibbosities. It inhabits Mauritania, as does the next.

DIDYMA. Thorax widely margined, two-horned behind; shells angular, with two gibbosities.

CASPICA. Ovate, slightly depressed; thorax excavated before and behind; shells carinate on each side, with alternate rough and smooth bands. A native of the Caspian sea.

SUBGLOBOSA. This, as its name imports, is subglobular; shells with smooth raised dots, and about four ribs, the outmost are carinate and crenulate. It is the *Tenebrio subglobosus* of Pallas. It inhabits southern France, and the deserts of Tartary. It moves very slowly, and is infested with the *Gordius*; and supposed to be a variety only of the *Pimelia rugosa*.

SILPHOIDES. Sides of the thorax pointed behind, jagged before; shells with three smooth striæ. A native of Mauritania.

TIBIALIS. Black, smooth; fore-shanks compressed, one-toothed. It inhabits Africa and Spain.

FEMORALIS. Black, smooth; thighs thick, channelled beneath. It is found in divers parts of Germany.

STRIATULA. Black; shells ovate-oblong, striate. A native of Spain.

LATICOLLIS. Oval, depressed, deep black, smooth; thorax very broad, margined, excavated before, and truncate behind; the shells are substriate. Found at the Cape of Good Hope.

VITTATA. Gibbous, black; shells united, glabrous, with three scarlet striæ and sutures on each side; the legs are unarmed.

b. *Feelers clavate.*

GAGES. Black; the thorax is a little rounded; the shells are mucronate and very smooth. Inhabits the southern parts of Europe. It resembles the *P. mortifaga*, but is twice as large.

SULCATA. Shells mucronate and grooved. It is found in the East; the shells are united with eight or nine smooth grooves. This insect is sold in Turkey as a specific against pains in the ears, and the bite of scorpions, and is boiled with butter, and eaten by the Turkish ladies for the purpose of making them grow fat.

***MORTISAGA.** Black; shells mucronate, sub-punctured. Found in various parts of Europe, as well as in this country. This inoffensive animal is regarded as a presage of the death of one in the family, by the common people in Sweden, if it is seen crawling about the house.

EXCAVATA. Thorax angular behind; shells with indented dots, somewhat pointed. It is a native of Coromandel.

GRANULATA. Black, depressed; shells with sub-spinous tubercles. It inhabits the Cape of Good Hope, as does the next.

BUPRESTOIDES. Ovate, black; shells united and very smooth.

DERMESTOIDES. Black, ovate; shells obsolete striate; shield emarginate. It is a native of Saxony.

OBTUSA. Thorax angular behind; body black; shells obtuse, striate. It inhabits Coromandel. This is the *Blasis striata* of Fabricius.

CAPENSIS. Ovate, depressed, black; thorax with dilated margins; it has four fore-shanks one-toothed. Found at the Cape.

EMARGINATA. Black, shells with crenate striæ; lip emarginate. It inhabits Morocco.

GRANULOSA. Black; shells with three raised lines, and small raised dots between them; thorax emarginate. This is an African insect.

SUBLEVIGATA. Depressed, black; shells with three raised smooth lines. A native of Morocco.

TRITIS. Black; shells grooved; the grooves smooth. Found in the sandy plains of Barbary.

SERRATULA. Thorax thickened at the edge; shells with three raised crenate lines. It inhabits the Cape of Good Hope.

FEMORATA. Black; hind-thighs channelled beneath, and covered with ferruginous down. A native of Germany.

TIBIATA. Black; shells striate; fore-shanks dilated and triangular. It is found at the Cape of Good Hope.

CRENATA. Thorax angular behind; of a grey-brown colour; shells with crenate striæ, obtuse. It inhabits Coromandel.

HELOPHOIDES. Oblong, black; shells very smooth. It is an European insect.

PUNCTATA. Black; antennæ ferruginous; shells striate, and

and punctured. It is a native of the South American islands.

CLATHRATA. Black; shells latticed; antennæ ferruginous at the tip. It inhabits South America.

SPECIOSA. Subovate, bronzed, winged; shells highly polished, striate, with coppery and green lines. It inhabits Brazil.

CHRYSOMELOIDES. Ovate, very rough; thorax longitudinally ridged; shells with three tuberculate lines. A native of Mauritania.

COSTATA. Subglobular, roughish, opaque; shells with each three crenulate ribs, the outmost carinate. A native of Siberia.

TORULOSA. Ovate, subglobular; shells tuberculate, convex, without ribs. It is found at the Cape of Good Hope.

AGRICOLA. Pale rufous; head and thorax black. It inhabits Germany.

SABULOSA. Black; shells rugged, pointed behind. Found in France, as is the next.

OCTO-STRIATA. Black; shells with eight punctured striæ disposed in pairs.

B. *Antennæ entirely filiform.*

a. *Feelers four, filiform.*

TRICUSPIDATA. Thorax with three teeth before; the body is of a grey colour. It is an Arabian insect.

SIMILIS. Thorax dusky, with three teeth; disk of the shells whitish, with three brown lines. Found in Barbary.

CRISTATA. Thorax with three teeth, crested; body variegated. Found in Arabia.

RETICULATA. Thorax angular at the sides; shells reticulate. It inhabits the Cape of Good Hope; as do the two following.

CORRUGOSA. Thorax smooth; glossy-black; shells rugged, with a single raised line.

VITTATA. Thorax subangular; shells black, with two white fillets, and a single raised line.

b. *Fore-feelers hatched-shaped, hind-ones clavate.*

LAMINATA. Black; thorax nearly square, smooth; shells grooved; fore-shanks incurved, with a round ferruginous appendage at the tip. It inhabits India.

PUNCTULATA. Black; thorax square, the edges slightly toothed; shells striate, punctured. It inhabits India.

***CÆRULEA.** Blueish; thorax suborbicular; shells striate. This is found in this country, and other parts of Europe.

LANIPES. Bronzed; shells ferrate and pointed. It is a native of Germany.

MARGINATA. Black; shells with a sanguineous edge all round. It inhabits Guinea. The shells are striate, black, with a blue gloss; the breast is rufous.

ÆRUGINOSA. Green bronzed; antennæ, shells, and legs black. Found at the Cape of Good Hope.

BICOLOR. Above dull brassy; beneath black; shells striate. It inhabits the South American islands.

***SERRATA.** Black; claws ferruginous; feelers projecting. This is an English insect, and found in other parts of Europe.

BARBATA. Black; feelers projecting; legs yellowish. A native of Saxony.

CANICULATA. Black; thorax channelled, impressed on each side; the shells are striate; the feelers projecting. This is a native of Saxony.

HÆMORRHOIDALIS. Head and thorax azure; shells

green, with crenate striæ; the tail is rufous. It is found in India.

LURIDA. Black; antennæ and legs brown. Inhabits Brazil.

LÆVIS. Black; thorax channelled, tapering behind; shells smooth. It inhabits Saxony.

EQUESTRIS. Black; shells with an abbreviated gold band. It inhabits Brazil.

MAURA. Black; thorax rounded on each side, smooth; shells with indented dots. It inhabits the East Indies.

MORIO. Black; thorax square, smooth; shells with punctured grooves. It inhabits North America.

NIGRITA. Black; thorax rounded at the edges; shells with crenate grooves. It inhabits Tranquebar.

PICICORNIS. Ovate, black; shells striate; antennæ and abdomen piceous. It inhabits the East Indies.

RUFIPES. Black; shells, antennæ, and legs rufous. Found in New Holland.

LONGIPES. Black; shells striate; legs long; second pair of shanks bearded. It inhabits the equinoctial parts of Africa.

CAPENSIS. Ovate, black; thorax smooth; shells striate. It inhabits the Cape.

MARGINATA. Ovate; thorax thickened at the edges; shells striate and smooth. It inhabits the Cape.

ATRA. Black; shells striate; antennæ and legs brown. It is a native of Germany.

***ANGLICA.** Black; thorax rounded before; shells striate, punctured; antennæ rufous at the tip. It is a rare insect, but a native of England.

HOTTENTOTTA. Black; shells with crenate striæ. This is found in France.

BANKII. Black; shells grooved, punctured; fore-thighs sharply toothed. It is found in Coromandel.

UNDATA. Black; thorax rufous, with black spots; shells rufous, with waved black bands. It inhabits Cayenne.

***QUISQUILIA.** Black; antennæ and legs ferruginous. It inhabits divers parts of Europe, and is found in silt and manure.

FLAVIPES. Brown; mouth, antennæ, and legs ferruginous; shells with crenate striæ. It inhabits the South American islands.

RUFICOLLIS. Ferruginous; shells striate, black. It inhabits Saxony.

CYANEA. Blue; thorax punctured; shells striate. It inhabits Germany.

VIOLACEA. Cylindrical, varied with fine polished blue and violet; abdomen red behind; shells striate, punctured.

LEUCOGRAPHIA. Ovate; thorax very rough, uneven; shells carinate, rough, with longitudinal, whitish, smooth stripes.

BUPARIA. Winged, black, glabrous; thorax lunate; jaws strong, toothed, as long as the head. It inhabits Spain, is described to be of the size of *Lucanus interruptus*, and it resembles the *Tenebrio fossor*.

PIZENI, in *Geography*, a town of Naples, in Calabria Ultra; 17 miles N.E. of Nicotera.

PIMENTA, or **PIMENTO,** in *Botany*, *All-spice*, or *Jamaica Pepper*, a species of the *Myrtus*, the *Myrtus pimenta*, (See **MYRTUS**.) It grows plentifully on the hilly parts of Jamaica, and is much cultivated there; because of the great profit from the cured fruit sent in great quantities yearly into Europe.

It flowers in June, July, and August, sooner or later, according to its situation and the different seasons for rain; and after its flowers, the fruit soon ripens. The flowers, with every part of the tree, breathe an aromatic fragrance.

Its

Its fruit is called *all-spice*, from its taste being supposed to resemble that of many different species mixed together.

There is little difficulty in curing and preserving this fruit for use, which is done thus: the negroes climb the trees and pull off the twigs with the unripe green fruit, and afterwards carefully separate the fruit from the twigs, leaves, and ripe berries; which done, they expose them to the sun from its rising to setting, for many days, spreading them thin on cloths, turning them now and then, and carefully avoiding the dews. By this management they become a little rugose or wrinkled, dry, and from a green change to a brown colour, and then they are fit for the market.

The ripe berries are very carefully separated from those to be cured; because their wet and plenteous pulp renders them unfit for cure.

The berries that are fully ripe lose the aromatic warmth for which they are so much esteemed, and acquire a taste perfectly resembling that of juniper berries, which renders them an agreeable food for the birds, the most industrious planters of these trees, which devouring them greedily, and muting the seeds, afterwards propagate these trees in all parts of the woods.

After the above described process is completed, which is known by the colour and rattling of the seeds in the berries, they are put up in bags or hogheads for the market. The aromatic odour and warm pungent taste of the pimento are qualities, which reside chiefly in the capsule, or rather cortical part of the dried berry. Its virtues are extracted by water, alcohol, and ether. The watery infusion is of a brown colour, and reddens litmus infusion. With solution of sulphat of iron it immediately strikes a deep black colour, and slowly lets fall a precipitate. Nitrate of mercury precipitates it of a yellowish-brown; superacetate of lead of a dirty green; and nitrate of silver of a deep reddish-brown colour. It also forms a precipitate with the infusion of yellow cinchona bark. The sulphuric and muriatic acids redden it, and throw down pale rose coloured precipitates. The nitric acid forms no precipitate, but gives it a yellow hue. The alcoholic tincture is rendered milky, and after a time precipitated by water; the ethereal, when evaporated in water, deposits drops of a greenish-yellow volatile oil, a pellicle of a pungent nauseous-tasted resin, and some extractive. Hence pimento appears to contain a volatile oil, resin, extractive, tannin, and gallic acid.

For dietetic purposes, to which it is chiefly applied, it is accounted the best and most temperate, mild, and innocent of common spices, and fit to come into greater use, and to gain more ground than it hath yet done. It surpasses most of the East Indian aromatics in promoting the digestion of meat, attenuating tough humours, moderately heating, strengthening the stomach, expelling wind, and doing those friendly offices to the bowels, we generally expect from spices. Phil. Trans. N^o 192.

This spice has been also long employed in the shops as a succedaneum to the more costly oriental aromatics. Distilled with water, it yields an elegant essential oil, so ponderous as to sink in water, in taste moderately pungent, in smell and flavour approaching to oil of cloves, or a mixture of those of cloves and nutmegs: the remaining decoction, inspissated, leaves an extract somewhat ungrateful but not pungent. To rectified spirit it imparts, by maceration or digestion, the whole of its virtue, together with a brownish-green tincture. In distillation it gives over very little to this menstruum, nearly all its active matter remaining concentrated in the inspissated extract.

Pimento is stimulant and tonic. It is useful as an adjunct to bitters in dyspepsia attended with much flatulence,

and in arthritic and hysterical affections. The watery infusion of it sweetened with sugar, and with the addition of a little milk, is readily taken by children, and serves as an excellent cordial in malignant measles, scarlatina, confluent small-pox, and the other exanthemata, when the fever assumes the typhoid type. But its principal use in medicine is to cover the disagreeable tastes of other remedies, or to give them warmth. The dose of the berries is from grs. v to ℥ij in powder, or in their entire state. The official preparations are the following; viz. Aquapimenta, L. E. D. Oleum pimentæ, L. E. D. Pilulæ opiatæ, E. Spiritus pimentæ, L. D. Syrupus rhamni, L.

The "Aqua pimentæ" of the London college, "Aqua myrti pimentæ," Edinb., "Aqua pimento," Dub., or pimenta water, is prepared by macerating half a pound of pimenta berries bruised in a pint of water for 24 hours; and by distilling with a sufficient quantity of water to prevent empyreuma, a gallon (10 pounds, Edinb.)

This water has the odour and aromatic quality of the Jamaica pepper, but it is not very agreeable to the taste. It is used as a carminative in dyspepsia.

"Oleum pimentæ," L. E. D. (see OIL of Jamaica Pepper), "Pilulæ opiatæ," (see PILLS, Opiate), "Spiritus pimentæ," L., "Spiritus pimento," Dub., Spirit of pimenta, is prepared by macerating for 24 hours two ounces (three ounces, Dub.) of pimenta berries bruised in a gallon of proof spirit, with water sufficient to prevent empyreuma; and then distilling a gallon by gentle heat. "Spiritus fructus myrti pimentæ," Edinb., Spirit of pimenta, is prepared with half a pound of bruised pimenta berries, in the same manner as spirit of caraway. This is an useful carminative in flatulent colic, atonic gout, and dyspepsia.

Syrupus Rhamni. See SYRUPUS RHAMNI.

PIMERIA, in *Geography*, a province in the domain of New Biscay, so called from the Pimas, a savage tribe. It is divided into two districts, the higher and the lower, and extends more than 100 leagues to the N. of Sonora. The savages here are rather pacific, and friends of the Spaniards. The climate is moist and cold, the rains being sometimes continued during a whole week in winter, while many torrents descend from the Sierra Madre. The Spaniards have left this province almost a desert, on account of the frequent invasion of the Apaches.

PIMOCHA, a town of South America, in the audience of Quito; 36 miles N.N.E. of Guayaquil.

PIMOLISA, in *Ancient Geography*, a fortified place of Cappadocia, in Pontus, on this side of the river Halys; and which gave name to the country of "Pimolifena," in the environs of this river.

PIMP-TENURE, in *Law*, a kind of tenure mentioned in our old writers, "Willielmus Hoppeshort, tenet dimidium virgatum terræ, per servitium cultodiendi sex damifellas scilicet meretrices, ad usum domini regis." 12 Ed. I.

PIMPELGONG, in *Geography*, a town of Hindoostan, in the circar of Kitchwara; 15 miles E. of Saurungpou.

PIMPERNEL, in *Botany* and the *Materia Medica*. See ANAGALLIS.

PIMPERNEL, *Water*, a species of speedwell or veronica; which see.

PIMPERNEL, *Round-leaved Water*. See SAMOLUS.

PIMPERNEL, *Yellow, of the Woods*. See LYSIMACHIA.

PIMPINELLA, is supposed by Ambrosinus, whose opinion is adopted by Linnæus, to be a corruption of *bipinella*, or *bipennula*, words expressive of the pinnate, or feather-like, structure of the foliage. Linn. Gen. 145. Schreb. 195. Willd. Sp. Pl. v. 1. 1471. Mart. Mill.

Dict.

PIMPINELLA.

Diét. v. 3. Sm. Fl. Brit. 331. Ait. Hort. Kew. v. 2. 159. Juff. 219. Lamarck Illustr. t. 303. (Anifum; Gært. t. 23.)—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatae*.

Gen. Ch. *General umbel* of numerous rays; *partial* of still more. *General and partial involucrem* wanting. *Perianth* scarcely discernible. *Cor.* Universal nearly uniform; flowers all fertile; *partial* of five, nearly equal, inflexed, heart-shaped petals. *Stam.* Filaments five, simple, longer than the petals; anthers roundish. *Pist.* Germen inferior; styles two, very short; stigmas capitate, nearly globose. *Peric.* none; the fruit ovate-oblong, separable into two parts. *Seeds* two, oblong, contracted towards the top, convex and striated on the outer side, flat on the inner.

Ess. Ch. *General and partial involucrem* wanting. *Petals* uniform, inflexed. *Fruit* ovate-oblong, striated. *Stigmas* nearly globose.

1. *P. saxifraga*. Common Burnet-Saxifrage. Linn. Sp. Pl. 378. Fl. Dan. t. 669. Jacq. Auftr. t. 395. Engl. Bot. t. 407. (*Bipinella*, five *Saxifraga minor*; Ger. Em. 1044.)—Leaves pinnate, variously cut; the radial leaflets roundish; the uppermost linear. *Seeds* smooth.—Native of dry gravelly or lime-stone pastures and hills, in various parts of Europe; frequent in England, flowering in July and August. The *root* is perennial, woody, aromatic, very hot and pungent. *Herb* roughish, and somewhat downy. *Stems* erect, rigid, round, striated, rather zigzag; the flowering branches elongated, and nearly naked. The leaflets of the radical *leaves* are ovate, obtuse, or roundish, very deeply and irregularly cut, some of them, from the same root, doubly pinnatifid in the most regular manner; the *leaves* on the upper part of the stem are simply pinnatifid, and linear; and the uppermost of all minute, as if abortive, consisting of little more than a lanceolate, concave, membranous *footstalk*. The *umbels* are terminal, solitary, naked, and smooth, with angular stalks. *Flowers* small, white or cream-coloured, almost perfectly regular. *Stigmas* capitate, which is unfortunately omitted in Engl. Bot., some of the *flowers* being occasionally found incomplete in that respect, as there represented. *Seeds* small, striated, smooth, crowned with the fleshy receptacle of the flower. *P. diffeâa*. Retz. Obs. fasc. 3. 30. t. 2. Willd. n. 4. Ehrh. Herb. 42; appears to us a mere variety, with triply pinnatifid leaves. Ehrhart's specimen, at least, is not specifically different from *saxifraga*, except in its smooth stem, a variable character.

2. *P. nigra*. Black-rooted Burnet-Saxifrage. Willd. n. 2. Berolin 110. (*Saxifraga hircina minor*, foliis fan-guiforbæ; Bauh. Hist. v. 3. part 2. 111.)—Stem striated, hairy. Leaves pinnate, downy; the radical ones with inversely heart-shaped, cut, obtusely toothed leaflets; those on the stem bipinnate, their leaflets wedge-shaped, toothed.—Native of dry ground in Germany. We know it not, but we follow Willdenow's *Prodromus Berolinensis*, in preference to his Sp. Pl., in the character, as agreeing best with Roth's Fl. Germ. v. 2. 342. The latter author describes "the terminal leaflet of the radical *leaves* constantly three-lobed." So it often is in *P. saxifraga*. The *root* of *P. nigra* is said to discharge a blue milky fluid, when wounded.

3. *P. magna*. Great Burnet-Saxifrage. Linn. Mant. 2. 219. Willd. n. 3. Engl. Bot. t. 408. (*P. major*; Hudf. 127. Fuchf. Hist. 608. Jacq. Auftr. t. 396. *P. saxifraga*; Ger. Em. 1044. Matth. Valgr. v. 2. 379.)—Leaves pinnate; leaflets ovate, pointed, cut; the terminal one three-lobed. Stem angular, furrowed, smooth.—Native of various parts of Europe. Found with us chiefly on

a chalky or lime-stone soil, in rather hilly places, flowering in July and August. The *root* is larger than that of the first species, but weaker in flavour and qualities. Whole plant larger, distinguished by the uniformity of its *leaves*, which are pointed, and doubly ferrated, smooth, and of a lighter green. *Stem* smooth, remarkably angular and furrowed. *Umbels* large, always white in England. Jacquin represents them of a pale blush, though he describes them as generally white, except in subalpine situations. On the alps of Switzerland, France, Savoy, &c. this species is always found with beautiful pink *flowers*. This is *P. flore rubro*; Riv. Pentap. Irr. t. 81. We have often, in contemplating its beauty, wished to detect some specific distinction, but in vain. Another acknowledged variety, though much differing in habit, is *P. orientalis*, Gouan. Illustr. 21. t. 15. Jacq. Auftr. t. 397. (*Pimpinella*; Riv. Pentap. Irr. t. 80.)—In this most of the *leaflets* are deeply, and even doubly, pinnatifid, with linear-lanceolate, entire, not ferrated, segments. Without the radical *leaves*, which agree with the common appearance of *P. magna*; and the weighty authority of Jacquin, who has traced its variations; few persons would believe this to be but a variety. Willdenow ought to have marked it γ , as differing from his β .

4. *P. Tragium*. Downy-seeded Burnet-Saxifrage. Villars Dauph. v. 2. 605. (*Tragium alterum* Dioscoridis; Column. Phytobaf. 75. t. 76. ed. 2. 61. t. 17, excluding Tournefort's synonym.)—Leaves pinnate; leaflets wedge-shaped, cut; the uppermost linear and entire. *Seeds* downy.—Found by Villars near Grenoble, at the foot of the mountain of St. Juste, near St. Paul of the three castles, amongst red ochry sand and fossil shells. We have a specimen from M. Thouin. Authors have passed over this species, though it appears to us very distinct, especially in its downy *seeds*, which serve to ascertain the synonym of Columba, though his plate must surely have been taken from a specimen of *P. saxifraga*; at least his *leaves*, except that on the middle of the stem, give no idea of our plant. The *root* of *P. Tragium* is woody, branched at the top, very pungent. *Stems* from six to twelve inches high, branched, spreading, round, striated, downy, almost leafless. Radical *leaves* numerous, simply pinnate, two inches long, rigid, minutely downy; wedge-shaped, not rounded, very acutely cut into about three segments. Villars says the leaflets of the first year's growth are more rounded. *Umbels* finely downy. *Stigmas* capitate. *Seeds* ovate, angular rather than striated, uniformly covered with fine, short, dense pubescence.

5. *P. bubonoides*. Round-leaved Burnet-Saxifrage. Broter. Lusit. v. 1. 462. Phytogr. fasc. 1. 41. (*Apium macedonicum*; Lusit. Grifl. Virid. 19, excluding the synonym. *A. lusitanicum rotundifolium*; Tourn. Inf. 305.)—Leaves twice or thrice pinnate, rounded, obtuse, crenate. Stem panicled. *Umbels* and *seeds* downy.—Native of sandy barren places in Portugal. Brotero. Loefling sent specimens from St. Ubes, with Tournefort's synonym, to Linnæus, who laid them undetermined into his genus of *Bubon*. We have others gathered by the Abbé Durand, in July, near Salée in Barbary. This is a striking and most distinct species, with all the characters of a *Pimpinella*. *Root* perennial, acrid, externally green. *Stem* often solitary, sometimes three or four from one root, herbaceous, annual, twelve or eighteen inches high, round, downy, thickish, much branched, and panicled, bearing a multitude of white *umbels*, very downy in every part; the *branches* and *stalks* accompanied by broad, solitary, ovate, often recurved *bractæas*, or rather abortive leaf-stalks. Radical *leaves* large, green, finely veined, slightly downy, twice or thrice pin-

nate; each leaflet near an inch long, rounded and obtuse, strongly crenate; oblique, entire, and cut away, as it were, at the base.

6. *P. capensis*. Cape Burnet-Saxifrage. Thunb. Prodr. 51. Willd. n. 6.—“Leaves thrice compounded; their segments acute. Stem striated.”—Found at the Cape of Good Hope.

7. *P. peregrina*. Nodding Burnet-Saxifrage. Linn. Sp. Pl. 378. Willd. n. 7. Ait. n. 4. Jacq. Hort. Vind. v. 2. 61. t. 131. (*Daucus tertius* Dioseoridis, secundus Plinii; Column. Ecphr. 108. t. 109.)—Radical leaves pinnate, rounded, crenate; upper stem-leaves wedge-shaped, cut. Young umbels pendulous. Seeds hispid.—Native of Italy, Spain, and France. Cultivated by Parkinson in 1640. Root perennial, spindle-shaped, white, aromatic and acrid. Stem eighteen inches high, erect, round, downy, not much branched. Radical leaves simply pinnate, rounded and crenate; the rest composed of narrow wedge-shaped leaflets; all somewhat rough or downy. Umbels few, large, white, perfectly pendulous, as if dying, before the flowers expand. Seeds ovate, minutely bristly.

8. *P. Anisum*. Anise. Linn. Sp. Pl. 379. Willd. n. 8. Ait. n. 5. Woodv. Med. Bot. t. 180. (*Anisum*; Riv. Pentap. Irr. t. 73. Ger. Em. 1035.)—Radical leaves three-cleft; stem-leaves acutely lacinated. Germs downy.—Native of Egypt. A hardy annual, but seldom ripening its seeds plentifully in our gardens. What are required for medical use, as an agreeable aromatic and cordial, are imported from Spain and Malta. The herb is a foot high, branched, slightly rough or downy, known by its jagged sharp leaves. Umbels always erect, white.

9. *P. dichotoma*. Fork-leaved Burnet-Saxifrage. Linn. Mant. 58. Willd. n. 9.—Leaves repeatedly compound, linear, channelled, acute. Footstalks with a membranous dilated wing. Stem paniced. Seeds globose, rough.—Native of Spain; sent by Loeffling to Linnæus, who alone has described it, nor do we find it any where figured. The stem is about a foot high, very much branched and paniced, with numerous white umbels. Leaves fleshy, roughish, in narrow channelled subdivisions, so that this species might well have been termed *abrotanifolia*. Their broad footstalks are conspicuous for a fine, broad, membranous, snow-white border.

10. *P. dioica*. Dwarf Burnet-Saxifrage, or Rock Parsley. Linn. Syst. Veg. ed. 13. 241. Willd. n. 10. Engl. Bot. t. 1209. (*P. pumila*; Jacq. Austr. t. 28. *P. glauca*; Linn. Sp. Pl. 378. Willd. n. 5. *Seseli pumilum*; Linn. Sp. Pl. 373. *Peucedanum pumilum*; Ger. Em. 1054.)—Leaves twice or thrice compound, linear, smooth. Umbels paniced. Flowers dioecious. Seeds ovate, smooth.—Native of Italy, Switzerland, France, and Austria; found on lime-stone rocks, in the south of England, but rarely. We no longer scruple to unite all the above synonyms of Linnæus, on the authority of his own specimens. This species is of humble growth, smooth, glaucous, with a stout, zig-zag, striated, purplish stem, divided into many alternate spreading branches. The umbels are disposed in a paniced manner, on reddish stalks. Flowers white, perfectly dioecious in effect, though not entirely in structure. Seeds roundish-ovate, striated, quite smooth. Dr. Wade has met with this rare plant, in great abundance, in pastures near the church of Athby, county of Meath, Ireland. Dr. Sibthorp found it on the summits of mount Athos, and the Bithynian Olympus.

PIMFINELLA, in *Gardening*, contains a plant of the annual kind, of which the species cultivated is the anise (*P. anisum*).

In these plants the seeds have an aromatic smell, and a pleasant warm taste, accompanied with a considerable degree of sweetness.

Method of Culture.—The seeds should be sown in the early part of April, on a dry warm border, where the plants are to remain; being afterwards properly thinned out, and kept free from weeds. These plants, however, seldom afford much profit by their seeds in this climate.

They produce variety in the borders, &c. of pleasure-grounds, as well as in pots in other places, when cultivated in that way.

PIMPLA, or PIMPLEUS, in *Ancient Geography*, one of those mountains which separated Macedonia from Thessaly, and which were consecrated to the Muses.

PIMPLE, in *Medicine*, a small puitule arising on the face.

By mixing equal quantities of the juice of house-leek, *sedum minus*, passed through paper, and of spirit of wine rectified by itself, a white coagulum of a very volatile nature is formed, which Dr. Burghart commends for curing pimples of the face; and says, that the thin liquor separated from it, with sugar-candy, is an excellent remedy for thick viscid phlegm in the breast. Satyr. Silesiac. Spec. 4. Ob. 2.

PIMPRAMA, in *Ancient Geography*, a town of India, towards the source of the river Indus, according to Arrian.

PIMSAN-IM, in *Geography*, a town of Chinese Tartary; 35 miles S.W. of Ning-yuen.

PIN, in *Commerce*, a little necessary implement, chiefly used by the women in adjusting their dresses.

The form and application of this little article need no description; but its consumption, and the number of hands it employs, are too considerable to be passed by unnoticed.

Pins are now mostly made of brass-wire: formerly they likewise made them of iron-wire, which, being blanched, like the others, passed for brass; but the ill effect of those pins has almost altogether discarded their use. The French, however, could not be driven off from them without several arrears of parliament. By a sentence of the lieutenant de police, July 1695, the seizure of some millions of those pins was confirmed, and the pins condemned to be burnt by the common executioner.

The pins most esteemed in commerce are those of England. The method of manufacturing this useful article, that has been long practised, is as follows. The brass wire, of which these implements are now almost wholly made, is generally too thick for being cut into pins. It is, therefore, reduced in size, by causing it to pass through a small hole in a piece of iron. When it has been reduced to a proper size, it is straightened, and subsequently cut into proper lengths; and again afterwards cut into smaller ones, each length being sufficient for making several pins. Each end of these pieces is pointed, so as to be sharp enough for penetrating, without difficulty, through linen, paper, &c. by either men or boys, seated before two small grinding-stones, or steel-mills, that are turned by a wheel, either by means of machinery or of the hand. These stones, or steel-mills, are used for making the rough point, and for smoothing them; and, therefore, they are careful to turn the wire, so as to render the points uniform and regular. The pin is afterwards cut off to the length that is wanted, from each end; and the process is repeated; till the whole of the length is pointed. The manufacture of the head is performed by the following operations. A piece of wire, suitable for heads, is spun on another; and thus the inside wire occasioning the upper

upper wire to be hollow, when drawn off, is then in the state required for being cut into heads: this is done by shears, every two rounds of the wire making a single head. The next process is that of heading the lengths, which is done by the operators or work-people taking up a single length, and thrusting it among the heads, and then immediately placing it under a heavy weight or hammer; when receiving the necessary blow, it is made secure; and thus the pin is completed in the first state. After this it is to be blanched or whitened, which is accomplished by putting the pin in a copper, containing tin and the lees of wine. When this is completed, the pin is in a state for sale, at the option of the buyer, either in a loose state, or stuck in paper for the convenience of the consumer.

Some successful attempts have been lately made by the well-known manufacturers, Messrs. Durnford, Francis, and Co., of Gracechurch-street, London, for putting on the heads of this very useful little article, with greater expedition and uniformity than had been previously done by others. We are not at liberty to disclose the process, which is ingenious, practicable, and expeditious; but to every effort for the improvement of this, and of every other article of British manufacture, we cannot but wish success.

The perfection of pins consists of the stiffness of the wire, and its blanching; in the heads being well turned, and the points filed.

The London pointing and blanching are in most repute; because our pin-makers in pointing use two steel-mills, (which are also occasionally used in the country,) the first of which forms the point, and the latter takes off all irregularities, and renders it smooth, and as it were polished; and, in blanching, use block tin, granulated: whereas in other parts they use a mixture of tin, lead, and quicksilver; which not only blanches worse than the former, but is also dangerous, on account of the ill quality of that mixture, which renders a puncture with a pin thus blanching very difficult to be cured.

The consumption of pins, and the number of artificers employed in the manufacture of them, are incredible. In Paris alone, there were anciently above one thousand people employed in it; and after the decline of this manufacture in the city, there have been annually sold above fifty thousand crowns worth of the pin-wire to the pin-makers of the neighbouring places, all brought thither from Stockholm. In the little town of Rugle, in Normandy, there were computed at least five hundred workmen employed in the pin manufacture; the whole town being peopled with them. Several thousand persons are employed in this manufacture, in various parts of our own country. Establishments of this kind are to be found in the Metropolis, Warwickshire, Gloucestershire, Essex, &c.

Notwithstanding that there is scarcely any commodity cheaper than pins, there is not any one that passes through more hands before they come to be sold. They reckon twenty workmen successively employed in each pin, between the drawing of the brass-wire, and the sticking of the pin in the paper.

Pins are distinguished by numbers; the smaller called from N^o 3, 4, 5; thence to the 14th; whence they are only accounted by two to two, viz. N^o 16, 18, and 20, which is the largest size.

Besides the white pins, there are also black ones made for mourning, from N^o 4, to N^o 10. These are usually of iron-wire.

Lastly, there are pins with double heads, of several numbers; used by the ladies to fix the buckles of their hair for the night, without danger of being disturbed by their pricking, &c.

The manufacture of both brass and iron pins is thought by some persons to be in a degree injurious to the pointer; as it is imagined he imbibes, in the course of some years, a quantity of the dust which flies off the wire, and which, in that case, must be pernicious. He is also liable, from the constant pressure of his thumb on the stones, to a weakness in it, which not unfrequently renders him incapable of continuing the operation of pointing.

We are sorry to learn that the pin manufacture is less prosperous than it was some years ago. This decline is partly owing to the diminished consumption of this article by our fair country-women, and of course partly to the excess of the quantity made above the regular demand; which has occasioned to the master-manufacturer not only an inconvenience, but a disproportionate return of profit for the capital which it employs. Upon the whole, it is thought, that this useful class of persons is decreasing in number; and that there are no very encouraging expectations of the manufacture's soon reviving and flourishing.

The first mention of pins that occurs in the English statute-book, is found in the statute of Richard III. in 1483, prohibiting foreign manufactures; and it appears from the manner in which pins are described in a statute of the 34th and 35th of Henry VIII. cap. 6, A.D. 1543, and the labour and time which the manufacture of them would require, that they were a new invention in this country, and probably but lately brought from France. However, in about three years time, they fell into the present ingenious and expeditious manner of making them.

One of the articles of the statutes of the ancient pin-makers of Paris was, that no master should open more than one shop for the sale of his wares, except on new-year's day, and the eve thereof: this we mention in an age of luxury and profusion, to recollect the agreeable simplicity of our forefathers, who contented themselves with giving pins for new-year's gifts.

Hence the custom of still giving the name *pins*, or *pin-money*, to certain presents, which accompany the most considerable bargains; in which it is usual to give something towards the pins of the wife, or children, of the person with whom the bargain is struck.

PINS, *Hook*. See *HOOK*.

PINS, *Protracting*. See *PROTRACTING*.

PIN, in *Artillery*, &c. an iron nail or bolt, with a round head, and generally with a hole at the end to receive a key. Of this there are many sorts, as axletree-pins, or bolts, bolster-pins, pole-pins, swing-tree-pins, &c. Musket-pins are small pieces of iron or wire that fasten the stock.

PINS, *Belaying*, in *Block-making*, are wooden pins, turned in a lathe, made of ash, 16 inches long, and $1\frac{1}{8}$ diameter at the upper end, which is turned as a handle; is $\frac{2}{3}$ ths the length, then shouldered in to $1\frac{1}{4}$ inch diameter.

PINS of *Blocks* are made of lignum-vitæ, or cocus; and sometimes, for common blocks, of green-heart, a wood which is imported from the West Indies. The diameter of the pin is the thickness of the sheave, and is turned in a lathe, except the head, which is left eight-square, to prevent its turning in the block, and is driven through the holes in the block and sheaves. Brass, iron, and lignum-vitæ sheaves, that are coated or plated, have iron-turned pins with square heads, and sometimes a hole in the point, for a forelock, to prevent their coming out. After the sheaves are fitted, the inside of the sheave-hole, at the arse of the block, is gouged hollow, to admit the rope, and answer with the sheave; and a small neat chamfer taken off the edges. See *BLOCK*.

PINS, in *Skip Building*, are various, according to their fe-

veral purposes; such are the bitt-pins, belaying-pins. Pins to prevent the bars of the capstan unshipping, are of iron, with an eye and a shoulder in their upper end. Connected with the eye is a short chain, fixed to the drum-head: thus they are always ready, when wanted, to put through the ends of bars, when shipped.

PINS of Boats, are pins of iron or hard wood, fixed along the gunwales of some, instead of row-locks, whose oars are confined by grommets; such are whale-boats, that occasionally row either end foremost. Pins and plates are iron pins, fitted in plates at convenient distances in the side of the pall-head of capstans, and occasionally drawn out to support the palls of the capstan.

PIN-Fallow, in *Agriculture*, a provincial term applied to a winter fallow.

PIN-Money, the name given to that allowance usually made by the husband to his wife, for her own spending.

Ad PINNAS bibere, a method of drinking anciently used among the Danes in England. The custom was, to fix a pin in the side of the wooden cup or wassal-bowl; which pin each guest was to drink bare, upon penalty of forfeiting.

PIN and Web, a horny induration of the membranes of the eye, not much unlike a cataract.

The pin and web is the same with what we otherwise call the pannus, unguis, pterygium, &c.

PIN Wheel of a Clock, the same with the striking wheel. See *WHEEL* and *CLOCK*.

PIN, in *Geography*, a city of China of the second rank, in the province of Chan-tong; 170 miles E.S.E. of Peking. N. lat. 37° 34'. E. long. 117° 40'.

PINA, RUY DE, in *Biography*, one of the earliest and best Portuguese historians, who flourished in the latter part of the 15th and half the 16th centuries. He was employed by Joam II. in many embassies of confidence and honour, signed the will of the monarch as public notary, was present at his death, and was the person who opened and publicly read his will. Emanuel heaped more favours upon him, and made him chief chronicler, an office of which he had already performed the duties. He lived some years after the death of this monarch, but the time neither of his birth nor of his death has been ascertained. He is supposed to have written the chronicles of Sancho I. and II., Alfonso II. III. IV. and V., of Diniz and Joam II. Some of these are disputed, and said to be the production of Fernam Lopes. Joam III. commissioned him to write the chronicle of his father Emanuel, for which he had collected materials, as the mighty events of that extraordinary reign took place. The celebrated Albuquerque, looking to him as the historian of his victories, sent him a present of jewels. "He," said his rival, Damian de Goes, "had the ruby rings, and I had the trouble." "Ruy de Pina," says Mr. Southey, "might have been called a chronicler of first rate merit, if Fernam Lopes had never written, who is infinitely the best of all chroniclers. But though coming immediately after that incomparable writer, Ruy de Pina still appears an excellent historian, and far superior to all who followed him."

PINACIA, ΠΙΝΑΚΙΑ, among the Athenians, tablets of brass, whereon the names of all the persons in each tribe duly qualified, and willing to be judges, or senators of the areopagus, being severally written, they were cast into a vessel provided on purpose; and into another vessel were cast the same number of beans, a hundred of which were white, and all the rest black; then the names of the candidates and the beans were drawn, one by one; and

those whose names were drawn out together with the white beans, were received into the senate. See *PROBULEUMA*.

In Solon's time there were only four tribes, each of which elected a hundred senators; so that the areopagus consisted of four hundred members; but the number of tribes being afterwards increased, the number of senators was consequently augmented by some hundreds; but the manner of election remained the same. See *AREOPAGUS*.

PINACLE, LA, in *Geography*, a cape on the W. coast of the island of Jersey; one mile S. of Grones.

PINACOTHECA, among the *Ancients*, a place where pictures, statues, and other curiosities were kept.

PINAGRA, in *Geography*, a strong mud-fort of Hindoostan, in Baramaal, taken and destroyed by the British in 1790; 14 miles W.S.W. of Darempour.

PINANG, the name of the kernel of the areca nut, and also a preparation made in the East Indies of this nut, or the mixture of the ingredients which they use for mastication. Into one of the firi or betel leaves, a piece of the areca nut, which is generally divided into six parts, one of which serves at a time, being put, with a little lime, the leaf is folded together, and kept in the 'mouth till the whole strength is drawn out of it. See *BETEL*.

PINANG, or *Pulo-Pinang*. See *PRINCE of Wales island*.

PINANPIRO, a town of South America, in the province of Quito; 10 miles N.N.E. of Quito.

PINARA, in *Ancient Geography*, a town of Asia Minor, being one of the largest in Lycia. It is placed by Strabo in the interior of this province, at the foot of mount Cragus.—Also, a town of Asia, in the northern part of Cælyria, upon the Gindarus, according to Pliny. Ptolemy places it in Pieria of Syria.—Also, an island of the Ægean sea, upon the coast of Ætolia.

PINARII, among the Romans, an order of priests belonging to Hercules, who offered sacrifices to that god in a solemn manner every year. They were in this service connected with the Potitii.

PINARUS, in *Ancient Geography*, a river of Asia, which rose in mount Amanus, and pursuing its course between two chains of these mountains, discharged itself into the Mediterranean, in the strait where was the bay of Iffus, in the gulf of Illicus.

PINAS, JOHN, in *Biography*, a painter of history, portrait, and landscape, born at Haerlem about the year 1596. He travelled to Italy for improvement, and afterwards obtained considerable reputation. He had a brother of the name of Jacques, who practised in the same style as John, but not with equal success.

PINAS, in *Geography*, a town of Spain, in Catalonia; 17 miles N.N.W. of Motril.

PINAS Island, an island on the coast of the gulf of Honduras, situated off Trivigillo bay.

PINAS Point, the eastern point of Panama bay. N. lat. 6° 15'. W. long. 80° 30'. The port of this name is on the same S.W. coast of the isthmus of Darien, near the point. The whole coast southward to cape Corientes abounds with pine-trees, whence the name.

PINASTELLA, in *Botany*, Dill. Giff. 168, so called by that author from its fancied resemblance to a pine-tree in miniature. See *HIPPURIS*.

PINCH, in *Music*, a kind of grace proper for certain instruments, particularly the harpsichord; it is formed by striking alternately the sound of the written note with the sound of the inferior note, and observing to begin and finish with the note which bears the pinch. The difference between the pinch and trill is this, that the latter is struck with the superior note, and the pinch with the inferior.

To **PINCH**, is to use the fingers instead of the bow, to make the chords of an instrument sound. There are some chord instruments which have no bow, and which are played only by pinching, as the lute, guitar, &c. and sometimes those with which the bow is generally used are pinched, as the violin, and violoncello; and this method of playing is marked in the Italian by the word *pizzicato*.

PINCHBECK, in the *Arts*, an alloy of copper and zinc, in various proportions. The copper in all these alloys should not be in less proportion than two of copper to one of zinc. This is scarcely malleable. The proportions in all cases should be definite. In the instance of these two metals proper compounds will be 1 to 1, 2 to 1, 3 to 1, &c. Any intermediate alloy will be defective. See *GOLD-coloured Metal*.

PINCHE, in *Zoology*, the *SIMIA Oedipus*; which see.

PINCHE, in *Geography*, a town of South America, in the province of Quito; 100 miles E.S.E. of Macas.

PINCHINA, one of the Cordilleras, in South America.

PINCHING, in *Gardening*, a sort of pruning, performed by nipping or breaking off the branches or springs of a plant, or tree, between the nails of two fingers.

Most gardeners hold, that pinching contributes to the abundance of the fruit, as well as of the branches; and they say that young shoots, thus lopped, are less apt to grow black and die, than when cut with a pruning-knife.

The season for pinching is chiefly in April or May; sometimes it is also practised in June and July. The fruits it is practised on, are chiefly melons, cucumbers, &c. Quintiny also prescribes it for fruit-trees.

It is chiefly to be practised on the large branches towards the top of the plant, or tree, which are useless, and yet consume a great quantity of good sap. It must rarely be employed on the large branches below; which ought always to be preserved for the winter's pruning, that they may yield others the following year, fit to fill the empty places. Nor must the operation of pinching be performed on the tender shoots; because, having only just sap enough for themselves, when they come to put forth more branches in the place where they are pinched, the small stock of sap allotted them, being divided, will starve them. The operation is to be performed within two or three eyes of the branch they grow out of.

The effect of pinching is, that instead of one useless, and, perhaps, hurtful wood-branch, a vigorous tree will put forth two or three at the eyes remaining; and the sap being thus divided, the branches will be less, and fit for both wood and fruit.

PINCHING, in the *Manege*, is when, the horse standing, the rider holds him fast with the bridle-hand, and applies the spurs just to the hairs of his sides, without pricking him.

If the horse is impatient under this, and draws himself up, and wants to go forward, it is a sign of vigour and mettle. But the purchaser ought to try the thing himself on the horse's back; for the jockies have the art of making the duller horse seem to have mettle in these trials. The purchaser must also distinguish between the restlessness of the horse under this treatment that arises from vigour, and that which arises from the horse's being ticklish, and which goes off immediately.

Pinching is accounted an aid, spurring a chastisement or correction.

PINCHUGA, in *Geography*, a town of Russia, in the government of Tobolsk. N. lat. 58° 20'. E. long. 96° 54'.

PINCKNEY, an island on the coast of South Carolina.

—Also, a district, formerly of the upper country of South Carolina, now divided into the districts of York, Chester, Union, and Spartanburgh.

PINCKNEYA, in *Botany*, so named by Michaux, (we are not responsible for the orthography,) in honour of one of his friends or patrons in America, probably Mr. Pinkney, once envoy to the British court; but nothing is recorded on the subject, either in the Flora of Michaux, or in the account of his life, where this tree is mentioned, (see Sims and Konig's Ann. of Bot. v. 1. 333,) as used by the inhabitants of Georgia to cure fevers, being allied to the *Cinchona*, or Peruvian bark. Michaux Boreal-Amer. v. 1. 103. Ait. Hort. Kew. v. 1. 372. Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. *Cal.* Perianth superior, in five deep acute segments, one (rarely two) of which is dilated into a large coloured leaf, deciduous. *Cor.* of one petal, funnel-shaped; tube thrice as long as the ordinary segments of the calyx, five-sided; limb in five deep, revolute, obtuse, nearly equal segments, half the length of the tube. *Stam.* Filaments five, awl-shaped, equal, inserted into the tube near its base, shorter than the limb; anthers oblong, incumbent. *Pist.* Germen inferior, roundish-oblong; style the length and form of the stamens; stigma thickish, in two obtuse lobes. *Peric.* Capsule globose, slightly compressed, with a furrow at each side, cartilaginous, thin, coated, of two cells and two valves, the partitions from the centre of each valve. *Seeds* numerous, horizontal, oval, depressed, with a membranous orbicular wing. *Receptacle* central, angular.

Eff. Ch. One segment of the calyx very large, leafy. Corolla funnel-shaped, five-cleft. Stamens prominent. Stigma bluntly two-lobed. Capsule inferior, of two cells and two valves. Seeds numerous, winged.

1. *P. pubens*. Downy Pinckneya. Mich. *ibid.* 105. t. 13.—Native of the banks of the river St. Mary in Georgia. Brought into England by the late Mr. John Frazer in 1786. It is a greenhouse plant, flowering in June and July. We are obliged to Mr. Frazer for fine specimens in flower and seed. Others are found in the herbarium of the younger Linnæus, which must have been collected before Michaux visited America, and we suspect they were sent by Bartram. This is a very handsome *shrub*, or small *tree*, with opposite downy *branches*. *Leaves* opposite, on downy stalks, oval, acute at each end, entire, a span long; naked, but roughish above; paler and rather downy beneath. *Stipules* between the footstalks, small, acute, deciduous. *Panicles* terminal, corymbose, many-flowered, downy, as well as the *calyx*, and outside of the *corolla*. *Flowers* an inch long, pale, streaked with purple. Their most conspicuous part is the large, oval, whitish, downy, leafy expansion, which takes the place of one segment of the *calyx*, as in the first and second species of *MUSSEUDA*; see that article. The *capsule* is as big as a large gooseberry, of a rigid, cartilaginous, but thin texture, with a deciduous skin. This genus is intermediate between *Cinchona* and *Musseuda*, but seems sufficiently distinct in its fruit from the former; as it unquestionably is from the latter, with which the habit most agrees. The name of *Bartramia* was defined for it, the original *Bartramia* being a *Triumfetta*; but there is now a very fine and distinct genus of mosses established under this appellation. See *MUSCI*.

PINCKNEYVILLE, in *Geography*, a post-town of South Carolina, and capital of Union district, on the S.W. side of Broad river, at the mouth of Pacolet, containing a handsome work-house, a gaol, and a few compact houses; 75 miles N.W. of Columbia.

PINCOS,

PINCOS, a town of Peru, in the diocese of Lima; 15 miles S. of Xauxa.

PINCZESTI, a town of European Turkey, in Moldavia; 28 miles S.W. of Jassy.

PINDA, a sea-port town of Africa, in the kingdom of Congo, on the left side of the Zaire; 125 miles W.S.W. of St. Salvador.—Also, a river of Africa, which runs into the Indian sea, S. lat. 13° 28'.

PINDALA, a town of Hindoostan, in Tellingana; 15 miles S. of Warengole.

PINDAMAHA, a town of Brazil, in the government of St. Paul; 80 miles N.N.E. of St. Paul.

PINDAR, in *Biography*, the most famous lyric poet of ancient Greece, was a native of Cynoscephale, near Thebes in Bœotia. The time of his birth is uncertain, but it is well known that he was at the height of his reputation at the time of the expedition of Xerxes, or B.C. 480. Although brought up under excellent instructors, he was chiefly indebted to his own exertions and genius for his peculiar excellencies. His chief patrons were Theron of Agrigentum and Hiero of Syracuse, whom he has commemorated in his poems. He celebrated the city of Athens in such lofty terms, as greatly to excite the displeasure of his countrymen the Thebans, who, on that account, imposed a fine upon him, which the Athenians not only doubly repaid, but erected a statue to his honour. His reputation was so great, that we find he was rewarded in the public assemblies of Greece with the prize, in preference to every other competitor; and as the conquerors at Olympia were the subjects of his compositions, the poet was courted by statesmen and princes. His hymns and pæans were repeated before the most crowded assemblies in the temples of Greece; and the priests of Delphi declared that it was the will of Apollo that her chief poet should receive half of all the first-fruit offerings that were annually heaped on his altars. This was not the only public honour which he received; after his death he was honoured with every mark of respect, even to adoration. His statue was erected at Thebes in the public place where the games were exhibited, and, six centuries after, it was viewed with the utmost sensations of pleasure and admiration by the geographer Pausanias. The honours which were paid him while alive were also shared by his posterity, and as a mark of their high attention and reverence, at the celebration of one of the festivals of the Greeks, a portion of the victim which had been offered in sacrifice was reserved for the descendants of the poet. Even the most inveterate enemies of the Thebans shewed a regard for his memory, and the Spartans spared the house which the prince of the Lyrics had inhabited, when they destroyed the houses and the walls of Thebes. The same sort of respect was likewise paid him by Alexander the Great, when Thebes was reduced to ashes. He died in the public theatre at an advanced age, about the year 440 B.C. The greatest part of his works has perished. He had composed some hymns to the gods, poems in honour of Apollo, dithyrambs to Bacchus, and odes on several victories obtained at the four greatest festivals of the Greeks, the Olympic, Isthmian, Pythian, and Nemean games. Of all these the odes are the only compositions extant, admired for sublimity of sentiments, grandeur of expression, energy and magnificence of style, boldness of metaphors, harmony of numbers, and elegance of diction. In these odes, which were repeated with the aid of musical instruments, and accompanied by the various inflections of the voice, with suitable attitudes, and proper motions of the body, the poet has not merely celebrated the place where the victory was won, but has introduced beautiful episodes, and by unfold-

ing the greatness of his heroes, the dignity of their characters, and the glory of the several republics where they flourished, he has rendered the whole highly beautiful, and in the greatest degree interesting. Horace has called our poet inimitable, and this panegyric will not, perhaps, appear too strong, since succeeding critics have agreed in extolling his beauties, his excellence, the fire, the animation and enthusiasm of his genius. Horace refers likewise to his pathetic and moral commemorations of departed excellence. It was probably in strains of this kind by which he acquired the epithets of *wise* and *divine* from Plato. Dionysius of Halicarnassus speaks of Pindar as the chief model among the lyric poets of what he denominates "severe and antique harmony," and he also extols his loftiness, energy, fertility, art, and strength of diction mixed with sweetness. Quintilian repeats these praises, but Longinus represents him as sometimes, when glowing with the brightest flame, undergoing a sudden extinction; and a more modern critic seems to join issue with the author of the "Sublime:" speaking of his odes, he says they have indeed those characteristics of fire, rapidity, and variety, for which he is so much celebrated by the critics of antiquity, but that fire is frequently obscured in smoke, and that variety is produced by digressions so excurive, that it is often scarcely possible to follow him, and trace their relation to his proposed subject." The best editions of this poet are those of Heyne, Gr. et Lat. Götting. 1773, 1798; the latter, which is in octavo, contains the Greek scholia. Moreri. Bibliogr. Dict.

PINDARIC, in *Poetry*, an ode formed in imitation of the manner of Pindar.

The Pindaric manner is distinguished by the boldness and height of the flights, the suddenness and surprisings of the transitions, and the seeming irregularity, wildness, and enthusiasm, of the whole.

Pindar, whence the manner takes its name, was of Thebes; he flourished about four hundred and sixty-eight years before Christ, and was contemporary with Æschylus. What we have remaining of his is a book of odes, all in praise of the victors at the Olympian, Pythian, Nemean, and Isthmian games; whence the first is entitled, the *Olympians*; the second, the *Pythians*; the third, the *Nemeans*; and the fourth, the *Isthmians*. Pindar is full of force and fire; his thoughts are sententious, his style impetuous, his sallies daring, and frequently running, as it were, at random; he affects a beautiful disorder, which, yet, is said to be the effect of the greatest art. See the preceding article.

As the subject which engaged his attention comprehended the praises of those who had gained the prize in the public games, it was necessarily very barren; and therefore he is perpetually digressive, and fills up his poems with fables of the gods and heroes, that have little connection either with his subject or with one another. Many of the histories of particular families and cities, to which he alludes, are now unknown to us, and therefore, though the ancients admired him greatly, he is often so obscure to modern readers, partly from his subjects, and partly from his rapid abrupt manner of treating them, that, notwithstanding the beauty of his expression, our pleasure in reading him is very much diminished.

The supposed irregularity of his numbers has made several of his imitators imagine themselves Pindaric poets, by the mere wildness and irregularity of their verses. None of our writers seem to have succeeded in the Pindaric character better than Cowley.

In a Pindaric ode, the plan of the whole ought to be drawn first, and the places marked out where the elegant sallies

fallies and wanderings may best be, and how the returns may be justly made to the subject. See ODE.

PINDING, a disease among lambs which are in the state of suckling. These animals, before they begin to eat grass, are liable to have a discharge from the bowels of a tough, glutinous, adhesive quality, which is apt to stick to the tail and buttocks, and when hardened by the sun, sometimes to glue them together in so close and firm a manner, as to prevent all possibility of their having any evacuations, and thereby soon to mortify and burst the intestines. The complaint is discovered in an easy manner, by the lambs appearing swelled and sick, with the upper and middle parts of their tails closely glued down, and they are as readily cured, by separating their tails from their buttocks, when the retained excrement will be discharged with a disagreeable smell. And the immediate recurrence of it will be prevented by rubbing the parts over with sand, friable clay, mud, or, what is better, a little tallow. But they must be well looked after for eight or ten days, until they begin to eat grass, when all danger from these obstructions is over. It is said to be most dangerous when the ewes are in high condition, and the season dry and backward; and seldom or ever to appear when the mothers are lean, and the weather disposed to be wet.

PINDLOCK, in *Geography*, a town of Germany, in the principality of Culmbach; three miles N.N.E. of Bayreuth.

PINDMISSUS, in *Ancient Geography*, a town of Asia, in Syria, situated on the mountains, near the small river Singas, on the W. side of the Euphrates, S.W. of Samofata.—Also, a town of Cilicia, near mount Amanus, belonging to the Eleuthero-Cilicians, according to Cicero, ad Attic. l. v.

PINDUS, a chain of mountains of Thessaly, extending to the S.W., consecrated to the Muses. This chain extended also towards Epirus, and was inhabited by the Athamanes, the Æthices, and the Perrhæbians.—Also, a town of Greece, in the Doride, placed by Strabo on the banks of a river of the same name, which discharged itself into the Cephissus. It is also called "Ciphus" by some authors. It was within the territory of this town that the Hellenes, driven from the Histiotide by the Cadmæans, went to establish themselves, according to Herodotus.

PINE, in *Botany*, &c. See BROMELIA and PINUS.

PINE, in the *Materia Medica* and *Rural Economy*. Although most species of fir possess in common the same medicinal properties, and all agree in affording the different products of the turpentine kind, yet some species produce these different articles in greater purity, and in more abundance, than others. From the wild pine, *Pinus sylvestris*, pinaster, or Scotch fir-tree, is obtained most plentifully the *pix liquida*, or tar, and from it may also be procured the common turpentine, and the white and yellow resins. The manner in which the tar is procured is by cutting the tree into pieces, and then enclosing them in a large oven constructed for the purpose, with a channel at the bottom. A sufficient degree of heat is then applied, by which the tar is forced out of the wood, and it runs off by the opening at the bottom: a process which is denominated "*distillatio per descensum*."

Upon an incision being made into the bark of the *Pinus abies*, or Norway spruce fir-tree, a clear tenacious fluid issues, which concretes into a resinous substance, known by the name of "*resina abietis*." This, after being boiled in water, and strained through a linen cloth, is called in the Pharmacopœias "*pix Burgundica*," or Burgundy pitch. But if the boiling of the native resin is continued till the water is

wholly evaporated, and wine vinegar is at this time added, a substance is formed, called "*colophonium*;" which see. See also *Burgundy Pitch*.

Linnaeus, and several other writers in the *Materia Medica*, refer the common turpentine to the "*pinus sylvestris*;" and the "*Terebinthina argentoratensis*," or Strasburgh turpentine, to the "*Pinus picea*," or silver fir-tree; yet upon the authority of Murray, who follows Du Hamel and Haller, Dr. Woodville ascribes the "*Terebinthina vulgaris*" to the latter pine, which pours out the turpentine so freely, that it is seldom necessary to make incisions through the bark for the purpose.

The "*Terebinthina Veneta*," or "*larigna*," as it may be more properly called, (because we are not wholly supplied with this article by the Venetians,) issues spontaneously through the bark of this tree, but is more commonly obtained by wounding the bark at the distance of about two feet from the ground, and inserting in the wood a small cannula, through which the turpentine flows into proper vessels, which are placed for its reception.

We may here observe farther, and more generally, that pitch, tar, resin, and turpentine, are all made from these trees by a very familiar process. In the spring time, when the sap is most free in running, they pare off the bark of the pine-tree, to make the sap run down into a hole, which they cut at the bottom to receive it; in the way, as it runs down, it leaves a white matter like cream, but a little thicker; this is very different from all the kinds of resin and turpentine in use, and it is generally sold to be used in the making of flambeaux, instead of white bees-wax. The matter that is received in the hole at the bottom is taken up with ladders, and put into a large basket; a great part of this immediately runs through, and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, and adding a large quantity of water, they distil this so long as any oil is seen swimming upon the water; this oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine: the remaining matter at the bottom of the still is common yellow resin. When they have thus obtained all that they can from the sap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with these billets; and setting them on fire, there runs from them, while they are burning, a black thick matter; this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out of which the tar runs like oil; if this hole be made too large, it sets the whole quantity of the tar on fire; but if small enough, it runs quietly out.

The tar, being thus made, is put into barrels; and if it be to be made into pitch, they put it into large boiling vessels, without adding any thing to it; it is then suffered to boil a while, and being then let out, is found, when cold, to be what we call pitch. Phil. Trans. N° 243. p. 291.

In a medical point of view it may be remarked, that the kernels of the nuts of the matured or stone pine, are of a balsamic and nourishing nature; good for consumptions, coughs, and hoarsenesses, restorative, and of service after long illnesses.

The leaves and tender tops of pines and fir are used for diet-drinks, and allowed to be antiscorbutic and diuretic. See CHOWDER-beer.

The resinous exudations of pines or firs are an important branch in the materia medica, and not only useful in the prescriptions of physicians, but have also been thought otherwise

wife conducive to health. Pliny tells us, that wines, in the time of the old Romans, were medicated with pitch and resin. And Jonstonus, in his *Dendrographia*, observes, that it is wholesome to walk in groves of pine-trees, which impregnate the air with balsamic particles. It is known that all turpentine and resins are good for the lungs, against gravel, also, and obstructions; and it is said, that the medicinal properties of those drugs are found in tar-water, which operates without heating the blood, or disordering the stomach. See PITCH, RESIN, TAR, and TURPENTINE.

PINE-Apple, in *Botany, Gardening, &c.* See BROMELIA.

PINE, Ground, a species of germander.

PINE, Heath, Low. See CORIS.

PINE, Screw. See PANDANUS.

PINE, Stinking ground. See CAMPHOROSMA.

PINE-Tree, in *Planting*, the name of a forest tree, of which there are several kinds that deserve cultivating; namely, the Scotch pine, which is so called from its growing naturally on the mountains in Scotland, and which is the tree that affords the red or yellow deal, which is the most durable of any of the kinds yet known. The leaves of this tree are pretty broad and short, of a greyish colour, growing two out of each sheath; the cones are small, pyramidal, and end in narrow points; they are of a light colour, and the seeds are small: this sort grows well upon almost every soil; they have been planted in great numbers upon peat-bogs, where they have made great progress; also in clay soils, where they have succeeded far beyond expectation; and upon sand, gravel, and chalk, they likewise thrive well; but as they do not grow near so fast upon gravel and sand as upon moist ground, so the wood is much preferable; for those trees which have been cut down upon moist soils, where they have made the greatest progress, when they have been sawn out into boards have not been valuable; the wood has been white, and of a loose texture; whereas, those which have been grown upon dry gravelly ground, have proved nearly equal to the best foreign deals. Those plantations, which have been made of late years of these trees, will in the next age, not only turn greatly to the advantage of their possessors, but also become a national benefit.

Another variety of this sort of tree is called *pineaster*, which is a large timber tree, and naturally throws out very large arms, some of which will be nearly horizontal. Some people think these trees very ornamental on this account; for, in the winter especially, they appear naked, and are of a yellowish colour; and being spread abroad thus large, and without order, in the mixture of the more regular sorts of growing firs, they make a good contrast. It must be observed, that the leaves of this sort are very large and long, and of a lighter green, than those of the Scotch fir, which is another circumstance to direct to its situation; and it must also be observed, that those long and large leaves which ornament the younger branches only, give the tree a majestic air; and as the larger arms appear naked to view, so the younger, being thus plentifully furnished, have a noble effect, besides what beauty it receives from its numerous cones. And Mr. Nicol remarks, that the timber of the Scotch pine or fir is found in highest perfection on the bleak and gravelly scites. In light sand, it is also found durable. But in the richer more loamy soils, although it grows apace while young, and flourishes exuberantly, it soon sickens, is short-lived; nor is the wood valuable, but short and brittle. On retentive, tilly clays, in which it is often planted, but from which, above all others, it should be excluded, it frequently becomes stunted about the twentieth or thirtieth year of its age; or when the roots have exhausted the upper soil, and begin to seek pasturage in the sub-soil, insomuch, that the

worms attack it on its limbs, anticipating, as it were, its dissolution.

And the white, or Weymouth pine, is one of the tallest trees of all the species, often growing a hundred feet high. The bark of this tree is very smooth and delicate, especially when young; the leaves are long and slender, five growing out of each sheath; the branches are pretty close, garnished with them, so make a fine appearance; the cones are long, slender, and very loose, opening with the first warmth of the spring: so that if they are not gathered in winter, the scales open and let out the seeds. The wood of this sort is esteemed for making of masts for ships. As the wood of this tree was generally thought of great service to the navy, there was a law made in the ninth year of queen Anne, for the preservation of the trees, and to encourage their growth in America: and it is only within these forty years past that these trees have begun to be propagated in England in any plenty, though there were some large trees of this sort growing in two or three places long before, particularly at the marquis of Bath's at Longleet; and sir Wyndham Knatchbull's in Kent; and it hath been chiefly from the seeds of the latter that the much greater number of these trees now in England have been raised; for although there have annually been some of the seeds brought from America, yet those have been few in comparison to the produce of the trees in Kent: many of the trees which have been raised from the seeds of those trees, now produce plenty of the seeds, particularly those in the garden of the late duke of Argyle at Whitton, which annually produce large quantities of cones.

According to Hanbury, the soil which this tree delights in most is a sandy loam; but it likes other soils of an inferior nature; and although it is not generally to be planted on all lands, like the Scotch fir, yet he has seen it luxuriant and healthy, making strong shoots, on blue and red clays, and other sorts of ground; on strong and stony ground, likewise, he has seen some very fine trees: so that, he believes, whoever is desirous of having plantations of this pine, need not be curious in the choice of his ground.

And this sort of pine will grow, Mr. Nicol says, in many different soils and situations, but seems to affect most a deep sandy loam. On chalky, gravelly, elevated grounds, it is found to luxuriate. It will also thrive in pretty strong clay, if lying on an open sub-stratum. It is impatient of stagnant water, nor will it flourish on a till. It is an elegant tree, and worthy of a place in all extensive plantations. He considers the timber as much superior in quality when produced on mountains, to that produced on richer soils, and in more sheltered situations. In fine, as already said, except on sandy or gravelly soils, this tree ought not to be planted. The many observations he has made in the Highlands confirm him in this opinion. The value of fir-timber (and that reared in the northern parts of the island, in soil and situation as above, is inferior to none) is known to every mechanic; nor is there any one at all acquainted with the arts, who does not know, that from this tree is extracted rosin, tar, &c.: articles which are so useful for many, especially naval purposes.

And the deciduous pine or larch is a lofty tree: its branches are slender, and incline downward: the leaves are of a light green; and like those of the cedar, are bunched together in a similar manner to the pencils or little brushes of the painter. In spring, when the leaves and flowers are breaking out, it has a particularly elegant appearance; and in the winter, it gives variety to a wooded scene by the bright colours of its naked branches: it is in good esteem as an ornamental tree, and its timber is of the more useful kind,

being

PINE-TREE.

being superior to that of most of the pine tribe. Indeed the utility of its wood has been highly extolled by ancient writers, and there can be no doubt but that it is an excellent wood for ship and house building. At Venice its wood is frequently used in building their houses, as well as in Switzerland, where those trees abound: so that, without doubt, the larch excels for masts for ships, or beams for houses, doors, windows, &c. particularly as it is said to resist the worm. It is remarked, that in Switzerland their houses are covered with boards of this wood, cut out a foot square; and as it emits a resinous substance, it so diffuses itself into every joint and crevice, and becomes so compact and close, as well as so hardened by the air, as to render the covering proof against all weather. But as such coverings for houses would cause great devastation in case of fire, the buildings are confined to a limited distance by an order of police from the magistrates. The wood, when first laid on the houses, is said to be very white; but this colour, in two or three years, is changed, by means of the sun and resin, to a black, which appears like a smooth shining varnish.

In his work on planting, Mr. Marshall has observed, that of the common larch there are several varieties. And that the flowers which the commonest sort exhibits early in the spring are of a delicate red colour; another sort produces white flowers at the same season, and these have a delightful effect among those of the red sort; whilst another, called the black Newfoundland larch, increases the variety, though by an aspect little differing from the others. There are also larches with greenish flowers, pale-red, &c. all of which are accidental varieties from seeds. These varieties are easily distinguished, even when out of blow: the young shoots of the white flowering larch are of the lightest green, and the cones when ripe are nearly white. The red-flowering larch has its shoots of a reddish cast, and the cones are of a brown colour; whilst the cones and shoots of the black Newfoundland larch are in the same manner proportionably tinged. The cones, which are a very great ornament to several sorts of the pines, are very little to these. Their chief beauty consists in the manner of their growth, the nature and beauty of their pencilled leaves, and fair flowers; for the cones that succeed them are small, of a whitish, a reddish, or a blackish-brown colour, and make no figure.

It is stated by the same writer, that the larch tree will grow extremely well on almost any soil, as well in clays as in other sorts; it thrives amazingly on the declivities of hills, and sides of high mountains; it is hardy enough to resist the severest cold, therefore proper for all exposed places: and, as the timber is so valuable, and its growth so quick, it is a tree which may be propagated to the great advantage of the owner. In fact, it is almost impossible to say too much in favour of this tree. It grows on the barrenest soils, and in the bleakest situations. In rich genial soils it luxuriates too much, grows top-heavy, and either loses its head, or is bowed down into an unsightly form, and becomes unprofitable. Its timber, whether in the water, or in contact with the earth, is durable almost beyond comparison.

In his Treatise on Planting, Mr. Nicol, however, observes that, which soil, in this country, when in a state of full maturity, this noble tree may most affect, remains yet to be known. If we may judge from appearances, we shall decide, that it will be found in the highest perfection of timber in the lighter more gravelly soils, and in elevated situations. That it luxuriates beyond every other tree, in all soils and situations, excepting those of a low, humid kind, is demonstrated in every instance where impartial comparison is made.

And it is observed by Marshall, that the Norway spruce

is a tree of as much beauty while growing, as its timber is valuable when propagated on that account. Its growth is naturally like the silver fir upright; and the height it will aspire to may easily be conceived, when we say that the white deal, so much coveted by the joiners, &c. is the wood of this tree; and it may perhaps satisfy the curious reader to know that from this fir pitch is drawn. The leaves are of a dark green colour; they stand singly on the branches, but the younger shoots are very closely garnished with them. They are very narrow, their ends are pointed, and they are possessed of such beauties as to excite admiration. The cones are eight or ten inches long, and hung downwards.

The better the soil is, the faster will the spruce fir grow, though it will thrive very well in most of our English lands. In strong loamy earth it makes a surprising progress; and it delights in fresh lands of all sorts, which never has been worn out by ploughing, &c. though it be ever so poor.

But why this tree has obtained the name of Norway, rather than Swedish or Danish spruce, is a question Mr. Nicol thinks of little importance. Certain it is, however, that many have been led to mistake on this account, supposing it to be the tree which produces the deal known by the name of Norway fir, and which is the produce of the Scotch fir beyond all doubt. The timber known by the name of Memel log is the produce of the spruce. It will, he adds, like all the fir tribes, grow in very different soils; but it is found in greatest luxuriance in deep sandy loams, where it hath freedom of space. On clays which are not retentive of water below, although moist of themselves, it will make surprising progress. On thin soils, and in bleak situations, it grows slowly; and may therefore become the better timber of any, on such: but here it becomes unsightly.

It cannot be cultivated in this country with such advantage as the Scotch fir, in respect of timber; but as an ornamental tree it outdoes it, where the soil is favourable. There are some majestic spruce firs at Duplin, the seat of lord Kinnoul, which are supposed the largest in the kingdom. From this tree pitch is also extracted in great abundance.

The American spruce fir, Mr. Marshall thinks, includes three varieties: the white Newfoundland spruce; the red Newfoundland spruce; and the black Newfoundland spruce; they however differ so little, that one description is common to them all. They are of a genteel upright growth, though they do not shoot so freely or grow so fast with us as the Norway spruce. The leaves are of the same green, and garnish the branches in the same beautiful manner as those of that species, only they are narrower, shorter, and stand closer. The greatest difference is observable in the cones; for these are no more than about an inch in length, and the scales are closely placed. In the cones, indeed, consists the difference of these three sorts: those of the white species are of a very light brown colour; those of the red species more of a nut brown or reddish colour; and those of the black species of a dark or blackish colour. Besides this, there is scarcely any material difference; though it is observable, that this trifling variation seems to be pretty constant in the plants raised from the like seeds. These sorts will often flower and produce cones when only about five or six feet high; and indeed look then very beautiful: but this is a sign of weakness in the plant, which it does not often fairly overcome. And it is added, that in many parts of England this is a very difficult tree to raise. It spends itself in cones, and becomes stunted and unsightly. Nevertheless, in the vallies of the Highlands, it thrives with full luxuriance and vigour; forming a rich picturable outline, possessing more strength of feature than most of the pines. As

PINE-TREE.

a standard in polished scenery, there are few trees that equal it; as may be seen at Enville and Fisherwick.

But Mr. Nicol thinks that these trees seem to affect most a deep black loam of a middling texture, and which is also sub-humid of itself, but does not retain stagnant water. They will also thrive well on sandy or gravelly loams of a moist nature. On dry shallow soils they languish; nor will they thrive on very exposed sites. In deep, sub-humid valleys, are to be found those most flatly in this country. They require full space; otherwise they become very un-fightly, even in youth. This tree, in America, arrives to great magnitude, and produces that vast store of masts and spars exported thence to Europe. Of this tree they also construct many ships of great burthen. But, in this country, the larch far excels it in any situation, and, as timber, is more valuable for this and all other purposes.

It becomes a fine ornamental detached tree on good soil, if allowed room to branch in its youth, and while nursing; but at the same time it requires shelter.

There are two varieties of the yellow-leaved fir, of which the silver fir is a noble, upright, full-growing tree. The branches are not very numerous, and the bark is smooth and delicate. The leaves grow singly on the branches, and their ends are slightly indented. Their upper surface is of a fine strong green colour, and their under has an ornament of two white lines, running lengthways on each side the midrib, on account of which silvery look this sort is called the silver fir. The cones are large, and grow erect; and when the warm weather comes on, they soon shed their seeds; which should be a caution to all who wish to raise this plant, to gather the cones before that happens.

The other variety is the balm of Gilead fir, which has of all the sorts been most coveted, on account of the great fragrance of its leaves: though this is not its only good property; for it is a very beautiful tree, naturally of an upright growth, and the branches are so ornamented with their balmy leaves, as to exceed any of the other sorts in beauty. The leaves, which are very closely set on the branches, are broad, and their ends are indented. Their upper surface, when healthy, is of a fine dark green colour, and their under has white lines on each side the midrib lengthways, nearly like those of the silver fir. These leaves, when bruised, are very finely scented; and the buds, which swell in the autumn for the next year's shoot, are very ornamental all winter, being turgid, and of a fine brown colour; and from these also exudes a kind of fine turpentine, of the same kind of (though heightened) fragrance.

The silver fir is exceedingly hardy, and will grow in any soil or situation, but always makes the greatest progress in a good rich loamy earth.

Mr. Nicol remarks, that the silver fir grows most luxuriantly in deep loamy earth; but there its wood is soft and spongy. It will thrive on bleak exposures, and thin gravelly or sandy soil. But that in which we may expect its timber in highest perfection, is a sandy loam, lying on a gravelly subsoil, or dry rock. On the mountains of Switzerland it is said to grow to a vast size, is excellent timber, and is used for many valuable purposes. In particular, turpentine is extracted from it; and it would seem that from this tree is extracted the true Venice turpentine; although there is an inferior kind extracted from the larch, which also passes under that name. As an ornamental tree, it is admisible in all extensive designs, and even on a smaller scale where variety is studied.

The latter sort must be planted in a deep, rich, good earth; neither will it live long in any other sort of soil. It matters little whether it be a black mould, or of a sandy

nature, provided it be deep, and there is room for the roots to strike freely. See PINUS.

In the raising of the trees, all the sorts are propagated by seeds, which are produced in their hard woody cones: the way to get the seeds out of these cones, which are close, is to lay them in the sun or before a gentle fire, which causes the cells to open, and then the seeds may be easily taken out. If the cones are kept entire, the seeds will remain good some years, so that the surest way to preserve them, is to let them remain in the cones until the time of sowing: if the cones are kept in a warm place in summer, they will open and emit the seeds; but if they are not exposed too much to heat, many of the sorts will remain entire some years, especially those which are close and compact; and the seeds, which have been taken out of cones after seven years, have grown very well, so that these may be transported to any distance, provided the cones are well ripened and properly put up.

The best time for sowing the seeds is about the end of March; when they are sown, the place should be covered with nets to keep off birds: otherwise, when the plants begin to appear with the husk of the seed on their tops, the birds will pick off the heads of the plants, and destroy them. Where the quantity of seed to be sown is large, so as to require a good space to receive them, they should be sown on an east or north-east bed of fine mould in the nursery, where they may be screened from the sun, whose heat is very injurious to the plants at their first appearance above ground. When the plants appear, they must be constantly kept clean from weeds; and in very dry seasons, if they are now and then gently refreshed with water, it will forward their growth; but this must be done with great care and caution, for if they are hastily watered it may wash the tender plants out of the ground, or lay them down flat, which often rots their stalks; and when this is too often repeated, it will have the same effect; so that unless it is judiciously performed, it will be the best way to give them none, but only screen them from the sun and wind.

In cases where the plants come up too close, it will be a good method to thin them gently about the beginning of July. The plants, which are drawn up may be planted on other beds, which should be prepared ready to receive them, as they should be immediately planted as they are drawn up, because their tender roots are soon dried and spoiled at this season of the year. This work should be done, if possible, in cloudy or rainy weather, and then the plants will draw out with better roots, and will soon put out new fibres again; but if the weather should be dry, the plants should be shaded every day from the sun with mats, and now and then gently refreshed with water. In drawing up the plants, there should be great care taken not to disturb the roots of those that are left remaining in the seed-beds, &c. so that if the ground be hard, the beds should be well watered some time before the plants are thinned, to soften and loosen the earth; and if, after they are drawn out, the beds are again gently watered to settle the earth to the roots of the remaining plants, it will be of great service to them; but it must be done with great care, so as not to wash out their roots, or lay down the plants. The distance which should be allowed these plants, is four or five inches row from row, and three inches in the rows, but some allow them more.

And in these beds the plants may remain till the spring twelve-months after, by which time they will be fit to plant out where they are to remain, as the younger the plants are, when planted out, the better they succeed; for though some sorts will bear removing at a much greater age, young plants

PINE-TREE.

plants put out at the same time will in a few years overtake the large ones, and soon outstrip them in their growth; and there is an advantage in planting them by saving the expence of staking and much watering which large plants require. It is often the case, with respect to plantations of pines, which were made of plants six or seven feet high, and at the same time others of one foot high planted between them, that in ten years the latter are better trees than the former, and much more vigorous in their growth; but if the ground, where they are designed to remain, cannot be prepared in proper time, the plants should be removed out of the seed-beds into a nursery, where they remain two years, but they should not continue much longer on any account.

The best season for planting out pine-trees, is the early spring, as March or the following month, just before they begin to shoot; for although the Scotch and some of the most hardy sorts may be removed in the autumn or winter, especially when they are growing in strong land, where they can be taken up with balls of earth to their roots; it is not a practice to be generally adopted in other cases.

In instances where these trees are planted in exposed situations, they should be put pretty close together, especially on the out-sides, that they may shelter each other; and when they have grown a few years, part of the plants may be thinned out, to give room for the others to grow. But this must be gradually performed, lest by too much opening the plantation at once, the air should be let in among the remaining trees with too great violence, and stop their growth.

And wherever large plantations of these trees are designed to be made, the best method will be to raise the plants either upon a part of the same land, or as near to the place as possible, and also upon the same sort of soil. A small piece of ground will be sufficient to raise plants enough for many acres. As the Scotch and larch kinds are capable of thriving upon the most barren sands, where scarcely any thing else except heath and furze will grow, they may in many situations be extensively planted; as there are many thousand acres of such land, which at present are of little benefit to any body, that might, by plantations of these trees, become of great value to their proprietors, and also a national benefit. It is in general the expence of making such plantations, that chiefly operates against such undertakings; though, when properly managed, it is much less than is commonly supposed, as the greatest of the expence is that of fencing them from the cattle, &c. for the other is trifling, as there will be no necessity of preparing the ground to receive the plants; and the charge of planting an acre of land with these plants will not be more than thirty shillings, where labour is dear, exclusive of the plants, which may be valued at forty shillings more. Many acres of land have been planted with these trees, which were covered with heath and furze, merely by digging holes to put in the plants, and afterwards laying the heath or furze, which was put upon the surface of the ground, about their roots, to prevent the ground drying; few of which have failed; the plants being mostly four years old from the seed. In five or six years, the pines have grown so well as to overpower the heath and furze, and destroy it, without their having had any further culture.

In regard to the distance at which they are generally planted in all large open situations, it is about four feet, but always irregular, avoiding planting in rows as much as possible; and in performing the work, great care is necessary not to take up the plants faster than they can be planted out, some men being employed in digging up the

plants, while others are planting. Those who take up the plants should be looked after, to see that they do not tear off their roots, or wound their bark; and as fast as they are taken up, their roots should be covered, to prevent their drying, and put into their proper situations as soon as possible. In planting them, it is advised that care should be had to make the holes large enough for their roots, as also to loosen and break the clods of earth, and put the finest immediately about their roots, then to settle the earth gently with the foot to the roots of the plants. Where these circumstances are duly attended to, and a proper season chosen for performing it, there will be very little hazard of their succeeding; but where plantations are made with plants which are brought from a great distance, and which have been so closely packed up as to heat, and cause the leaves to become yellow, few of them will grow in a perfect manner.

In general, after the plantations are made, the only care they require, for four, five, or six years, is to secure the plants from cattle, hares, and rabbits; for if these are admitted to them, they make great destruction in a short time: as where the branches are gnawed by hares or rabbits, it greatly retards the growth of the plants, if it does not wholly destroy them. In about this length of time after planting, the branches of the young trees meet, and begin to interfere with each other; therefore they require a proper thinning out. Some, however, advise pruning off the lower branches; but this must be done with great caution. The lower tier of branches only should be cut off: this should be performed in September, at which time there will be no danger of the wounds bleeding too much; and the turpentine will harden over the wounds as the season grows cold, and prevent the wet from penetrating them. These branches should be cut off close to the stems of the plants, and care be taken not to break any of the remaining branches of the young trees. This work should be repeated every other year, at each time taking off only the lower tier of branches: for if the plants are much trimmed, it will greatly retard their growth, as it does in general that of all trees; but as these trees never put out any shoots where they are pruned, so they suffer more from amputation than those which do. It is probably the best practice, in all cases, to thin out the trees so as to let them have sufficient room and air, as they can never be pruned in the branches without great injury. And in about twelve or fourteen years, they will require more thinning, where the plants have made good progress; but this should be gradually performed, beginning in the middle of the plantation first, leaving the outside close, to screen those within from the cold, and by degrees coming to them, when those which were first thinned will have had time to get strength, and not be in danger of suffering from the admission of cold air. When these plantations are thinned, the trees should not be dug up, but their stems cut off close to the ground, as their roots never shoot again, but decay in the earth; so there can be no harm in leaving them, and the roots of the remaining plants are not injured. The trees which are now cut will be fit for many purposes: those which are straight will make good putlocks for the bricklayers, and serve for scaffolding poles; so that there may be as much made by the sale of these as will defray the whole expence of the planting, and probably also interest for the money first laid out for the whole.

And as the upright growth of these trees renders their wood the more valuable, they should be left pretty close together, in order to draw each other up, and grow tall. The naked stems of the trees sometimes rise more than

seventy feet in height, and as straight as possible; and as many boards have been fawn from one of them, as laid the floor of a room near twenty feet square. If these trees are left eight feet afunder each way, it will be sufficient room for their growth: therefore, if, at first thinning, a fourth part of the trees is taken away, the others may stand twelve or fourteen years longer, by which time they will be of a size for making ladders, and standards for scaffolding, and many other purposes; so that from this sale as much may be made, as not only to pay the remaining part of the expence of planting, if any should be wanting in the first, but rent for the land with interest; and the standing trees for fortunes for younger children, or other purposes.

But the great use and value of these sorts of trees will be seen more fully under the proper heads. See PINE, *supra*.

PINE-Tree, in *Gardening*, the common fir-tree. See PINUS.

PINE-Apple, in *Metallurgy*, a word used to express a sort of mould, used in the refining of silver. It has this name from its shape, resembling the fruit of that name.

When the refiners have taken the mixture of the silver and mercury together out of the cauldron, and strained it through two coarse wetted cloths, to make it the thicker, they then beat it with a sort of battledores, to drive out yet more of the quicksilver; and straining it again after this, they take out the remaining thick amalgam, and forming it into little pellets, they put these carefully into the moulds called pine-apples, pressing them down. The amalgam, when put into these vessels, or moulds, is usually so rich as to be about one-fifth silver. The manner of diverting this of the quicksilver afterwards is by means of fire; in which the quicksilver rises in vapour, and the silver is left pure behind; but the carelessness of the workmen in doing this, and particularly the using bad vessels, or the not luting them close, causes a waste of this mineral greater than could be conceived. Alonso tells us, that in the city of Potosi alone, at the time of his writing, when the trading in metals ran but low, above thirty thousand pieces of eight were wasted in quicksilver that was lost one year with another. To prevent this, they then principally studied the means of keeping the silver as dry of quicksilver as they could, in the pine-apple; but it then holding four-fifths of the whole mass in quicksilver, the great waste was in the separating it afterwards. See POTOSI.

PINE-Martin, in *Zoology*. See MUSTELA *Martes*.

PINE-Salt, a name given to a preparation of the bark of the pine-tree, used as a sort of seasoning to food in the manner in which we use salt.

The Laplanders are very fond of this; and the manner of their preparing it is given in Scheffer's history of that country. They peel off the bark from the lower part of the bodies of those trees, and separating the outer rough part, they take the inner bark, which they carefully divide into its several thin coats: when they have thus reduced them to as thin pieces as they can, they expose them to the sun in their summer months to dry; and when thoroughly dried, they tear them into thin and narrow slips, and put them up in boxes made of the outer bark of other trees fresh taken off. They bury these boxes in deep holes dug in the sands, and let them remain thus one day; on the day following, they bring together a number of stumps of trees, and other wood, and laying them over the place where the bark is buried, they set them on fire; the next day they take out their buried boxes, and the heat having penetrated so deep into the earth in a mild degree, the bark is found to have been greatly affected by it, and to have received a red co-

lour, and a very agreeable flavour, somewhat sweetish. This is their general sauce: they eat it with all their food, as we do salt; but it has so little of the nature of salt, that the name is ill adapted to it.

There is another vegetable substance, which, though of a disagreeable taste to us, yet custom teaches them to be fond of. This is the angelica petrosa: they cut the large stalks of this plant before it runs to seed, and roast them; they eat this in considerable quantities with their pine-salt, and esteem it not only an agreeable, but a more than ordinary wholesome sort of food.

PINE, in *Geography*, a township of America, in Allegany county, Pennsylvania, containing 588 inhabitants.

PINE-Creek, a township of America, in Lycoming county, containing 397 inhabitants.

PINE-Creek, a river of America, in Pennsylvania, which runs into the west branch of the Susquehannah, N. lat. $41^{\circ} 11'$. W. long. $77^{\circ} 22'$.

PINE River, a river of America, which runs into lake Huron, N. lat. $45^{\circ} 42'$. W. long. $84^{\circ} 25'$.—Also, a river of America, which runs into the Wabash, N. lat. $40^{\circ} 15'$. W. long. $87^{\circ} 18'$.—Also, a river of Canada, which runs into lake Huron, N. lat. $44^{\circ} 44'$. W. long. $80^{\circ} 26'$.

PINE Island, a small island in the gulf of Mexico, near the south coast of West Florida. N. lat. $30^{\circ} 18'$. W. long. $88^{\circ} 18'$.

PINEA, in *Botany*. See PINUS.

PINEA, or Pigne, in *Commerce*, a term used in Peru and Chili, for a kind of light, porous masses or lumps, formed of a mixture of mercury and silver-dust from the mines.

The ore, or mineral, of silver, being dug out of the veins of the mine, is first broken, then ground in mills for the purpose, driven by water with iron pebbles, each of two hundred pounds weight. The mineral, thus pulverised, is next sifted; then worked up, with water, into a paste; which, when half dry, is cut into pieces, called *cuerpos*, a foot long, weighing each about two thousand five hundred pounds.

Each cuerpo is again kneaded up with sea-salt, which, dissolving, incorporates with it. They then add mercury, from ten to twenty pounds for each cuerpo, kneading the paste afresh until the mercury be incorporated with it. This office being exceedingly dangerous, on account of the noxious qualities of the mercury, is always made the lot of the poor Indians.

This amalgamation is continued for eight or nine days; and some add lime, lead, or tin ore, &c. to forward it; and, in some mines, they are obliged to use fire. To try whether or no the mixture and amalgamation be sufficient, they wash a piece in water; and if the mercury be white, it is a proof that it has had its effect; if black, it must be further worked.

When enough, it is sent to the lavatories, which are large basons that empty successively into one other. The paste, &c. being laid in the uppermost of these, the earth is then washed from it into the rest by a rivulet turned upon it; an Indian, all the while, stirring it with his feet, and two other Indians doing the like in the other basons.

When the water runs quite clear out of the basons, they find the mercury and silver, at bottom, incorporated. This matter they call *pella*, and of this they form the *pineas*, by expressing as much of the mercury as they can; first, by putting it into woollen bags, and pressing and beating it strongly; then, by stamping it in a kind of wooden mould,

of an octagonal form, at the bottom of which is a brass plate pierced full of little holes.

The matter, being taken out of the mould, is laid on a trivet, under which is a large vessel full of water; and the whole being covered with an earthen head, a fire is made around it.

The mercury still remaining in the mass is thus reduced into fumes, and at length condensing, it is precipitated into the water, leaving behind it a mass of silver grains of different figures, which only joining or touching at the extremes, render the matter very porous and light.

This, then, is the pinea, or pigne, which the workmen endeavour to sell secretly to vessels trading to the South sea; and from which those who have ventured to engage in so dangerous a commerce, have made such vast gains. Indeed, the traders herein must be very careful; for the Spanish miners are errant knaves, and to make the pignes weigh the more, they make a practice of filling the middle with sand, or iron.

PINEAL GLAND, in *Anatomy*, a small conical body, about the size of a pea, in the brain. See **BRAIN**.

PINEAU, GABRIEL DU, in *Biography*, a celebrated French lawyer, was the son of an eminent advocate at Angers, where he was born in 1573. He practised first at his native place, then at Paris, and afterwards was created by Mary de Medicis her master of requests. In her differences with the court, she fought to support herself by his counsels; but, faithful to his sovereign, he continually advised her to an accommodation, which was at length effected. By Lewis XIII. he was nominated mayor and captain-general of Angers in 1632. The integrity and impartiality with which he performed the duties of his station, caused him to be called the father of the people. His house was, at length, made a kind of academy, in which conferences were held on points of law for the instruction of members of the profession, and others. He was exact in the performance of his religious duties, and exemplary in his conduct. He died at the age of 71, in the year 1644. His writings are, "Latin Notes on the Canon Law, in opposition to those of Du Moulin;" "A Latin Commentary on the Custom of Anjou;" "Consultations on several important Questions relative to the Custom of Anjou and to the French Law, with Dissertations on various Subjects:" these were reprinted in 2 vols. folio, 1725. **Moreri**.

PINEDA, JUAN DE, a native of Medina del Campo, and author of an universal history under the title of "Le Monarquia Ecclesiastica." He was an indefatigable writer; his commentaries alone filled 6826 leaves in folio. The most useful of his labours, however, was that of editing and abridging a very curious book, entitled "El Pazo Honroso defendido por Suero de Quinones," of which a new edition was printed at Madrid in 1783. Pineda was a Franciscan, and lived to the age of fourscore. There is another writer of the same name, who lived about the same time, a Jesuit, who was of such estimation, that once when he passed through Evero, he was received in the Jesuit college there, and a monument was afterwards erected with this inscription, "Hic Pineda fuit." The task of compiling the great "Index Expurgatorius," published in 1640, was performed by him. He also published a funeral oration for that extraordinary woman Donna Luísa de Carvajal y Mendoza, in the English seminary at Seville.

PINEDA, in *Geography*, a town of Spain, on the coast of Catalonia; 12 miles N.E. of Mataro. N. lat. $41^{\circ} 37'$ E. long. $2^{\circ} 35'$.

PINEG, a town of Russia, in the government of

Archangel, on the Pinega; 48 miles E. of Archangel. N. lat. $64^{\circ} 30'$ E. long. $41^{\circ} 26'$.

PINEGA, a river of Russia, which rises in the province of Usting, and runs into the Dwina; eight miles E. from Cholomgori, in the government of Archangel.

PINEGROVE, a township of America, in Berks county, Pennsylvania, containing 1290 inhabitants.

PINEI nuclei Maluccani five pergatorii, *J. B. Pinus Indica nucleo purgante C. B. Pinei nuclei Maluccani*. Park., in *Botany*, a species of the croton in the Linnæan system. There grows, says Acofta, in some gardens of Malabar, and also wild, in some woods, a tree of the bigness of a pear-tree, whose leaves are of a watery-green beneath, and of a dead green on the upper face, and are very tender and soft. They are of a very acrid taste, and vellicate the tongue for a long while afterwards: the fruit is triangular, of the size of a silberd, and divided into many capsules, containing each a round sort of white or dark greenish seed, equal to a pine-kernel, when taken out of its shell.

The Indians, as Acofta says, take a couple of the kernels, peel them, and then pound them, and mix them in clysters, against difficulty of urine, and the pain of the sciatica; or exhibit them in cock-broth, for the evacuation of putrid, slimy, grofs, and cold humours, and particularly for the cure of an asthma. They anoint the impetigo with these kernels, bruised in water, and so cure it; but they are very burning. The cathartic pine-kernels, as Monardes says, purge very strongly bile, phlegm, and water; and though milder than silberds, excite vomiting. When roasted, they operate with less violence, and fewer gripes. They are exhibited in chronic diseases, and have a peculiar virtue of evacuating grofs humours.

The fruit of this tree is the grana tiglia of other writers. It is intensely hot and acrimonious; and so violent an evacuant, that it cannot be taken with any tolerable safety. This, as well as the pinhones Indici, and avellana purgatrix, which is a species of the jatropha, in the Linnæan system, yield upon expression a considerable quantity of oil, impregnated more or less with the taste and purgative quality of the seeds; but they all appear too drastic to be ventured on in substance. The wood and leaves of the plants are likewise strong cathartics.

PINELLI, GIANVINCENZO, in *Biography*, an eminent patron of literature, was born of Genoese parents, at Naples, in 1535. From a very early period he entered with so much earnestness into literary pursuits, that besides the ancient and several modern languages, there was scarcely any branch of science which he had not acquired. At the age of twenty-three he left Naples for Padua, where he had improved himself by his acquaintance with many eminent scholars. In 1561 he was recommended to Philip II. as the fittest person to undertake a history of Charles V. He is applauded by other learned persons of high estimation on account of his literary and moral qualifications. Though from his rank and situation he might have aspired to the most important stations, yet his fondness for letters, joined to a delicate habit of body, led him to pass his days in retirement. His house was a kind of academy, frequented by the literati, who found in him a munificent patron, and an enlightened director of their studies. He collected a numerous library of books; expensive mathematical and astronomical instruments; a cabinet of fossils and minerals; together with maps, plates, and every thing that could facilitate learned research. He died in 1601, and the fate of his fine library was very remarkable. After his death, the senate of Venice set its seal upon his manuscripts, and took away all that related

to the affairs of the republic, amounting to 200. There were besides 14 chests of MSS., which, with 116 chests of printed books, were embarked in three ships to be conveyed to Naples, where his heirs resided. One of them fell into the hands of the corsairs, who, considering the books as mere lumber, threw them overboard; the rest were scattered on the beach at Fermo, which was entirely covered with papers. These were totally disregarded, till the bishop of the place having collected all he could, sent them to Naples. In this state the library was purchased by cardinal Borromeo at the price of 3400 gold crowns.

PINES, *Island of*, in *Geography*, a small island on the N.W. of Terra Firma, about 41 leagues E. of Porto Bello, which forms a good harbour, with two other small islands and the main land. N. lat. $9^{\circ} 12'$. W. long. $80^{\circ} 15'$. The river of Pines is five miles from the above harbour.

PINES, *Pinez*, or *Pinas*, an island in the Caribbean sea, near the S.W. coast of Cuba, about 25 miles long, and 15 broad. N. lat. $21^{\circ} 30'$. W. long. $83^{\circ} 25'$.

PINES, *Bay of*, a bay on the coast of West Florida. N. lat. $30^{\circ} 20'$. W. long. $88^{\circ} 21'$.

PINES, *Island of*, an island in the South Pacific ocean, near the coast of New Caledonia; about 15 or 16 miles in length, in a S.E. and N.W. direction, high in the central part, and sloping towards the extremities. S. lat. $22^{\circ} 38'$. E. long. $167^{\circ} 38'$.

PINET, ANTHONY DU, in *Biography*, lord of Norroy, who flourished in the 16th century, was a native of Befançon in the Franche Comté, concerning whom we know nothing but that he was zealously attached to the Protestant religion, in behalf of which he wrote several books. He was likewise author of "Plans, Draughts, and Descriptions of several Towns and Fortresses, as well in Europe, Asia, and Africa, as in the Indies and America, their foundations, antiquities, and manners of living, &c." He translated Pliny's Natural History in 2 vols. folio, and many other works of repute. Bayle. Moreri.

PINETUS, in *Ancient Geography*, a town of Spain, on the route from Bracara to Asturica, between Ad Aquas and Roboretum, according to Antonine's Itinerary, attributed by Ptolemy to the Callaici.

PINETZKOI, in *Geography*, a town of Russia, in the government of Archangel, on the Dwina; 60 miles S.S.E. of Archangel.

PINEVILLE, a town of America, in South Carolina, in St. Stephen's district, which has a flourishing academy, between 20 and 30 dwelling houses, 150 white inhabitants, and 300 negroes. In its vicinity is a valuable quarry of brown iron-stone, the only one found in the low country of Carolina.

PINEY, a town of France, in the department of the Aube, and chief place of a canton, in the district of Troyes; 12 miles N.E. of Troyes. The place contains 1456, and the canton 5920 inhabitants, on a territory of 250 kilometres, in 13 communes.

PING-CHAN, a city of Corea; 35 miles S. of Hoang-tcheou.

PING-CHAN-PO, a small island, with a town, near the S. coast of Corea. N. lat. $34^{\circ} 8'$. E. long. $126^{\circ} 22'$.

PING-HAI, a town of Corea; 115 miles S.E. of King-ki-tao. N. lat. $36^{\circ} 47'$. E. long. $128^{\circ} 41'$.

PING-ING, a town of Corea; 40 miles S. of Koang-tcheou.

PING-KING, a city of China, of the first rank, in Koei-tcheou. N. lat. $26^{\circ} 38'$. E. long. $106^{\circ} 56'$.

PING-LIANG, a city of China, of the first rank, in Chen-fi. N. lat. $35^{\circ} 35'$. E. long. $106^{\circ} 18'$.

PING-LO, a city of China, of the first rank, in Quang-fi. N. lat. $24^{\circ} 22'$. E. long. $110^{\circ} 4'$.

PINGNAVIR, a town of Africa, in Querimba. S. lat. $11^{\circ} 55'$. E. long. $41^{\circ} 10'$.

PINGRÈ, ALEXANDER-GUY, in *Biography*, a French mathematician and astronomer, was born at Paris in 1711. In 1727 he became a member of the canons regular of the congregation of France. He was intended for the church, but after a few years' study of the theology he devoted himself entirely to the sciences. In 1749 he was appointed a member of the Academy of Sciences in Rouen, and was elected to fill the office of astronomer, and attained to first rate excellence. His earliest production, as an author, was the "Calculation of an Eclipse of the Moon," on the 23d of December 1749. In May 1753 he was elected correspondent of the Academy of Sciences at Paris, after having sent them an observation of the transit of Mercury, which he made at Rouen. He was next appointed librarian of the abbey of St. Genevieve, obtained the construction of an observatory, and was furnished by the abbot and chapter with a six-foot telescope, while he had the loan of an excellent quadrant from the academy. At the desire of Monnier, he next engaged in calculating "A Nautical Almanack," to enable navigators more easily to ascertain the longitude by means of lunar observations. He calculated a table of the eclipses visible of the sun and moon from the commencement of the Christian era to the year 1900, and afterwards a table of the eclipses visible from the northern pole to the equator, for a thousand years before our era. The utility of these labours for verifying historical dates, induced the Academy of Inscriptions to insert a part of them in the 42d volume of their Memoirs. He published the "State of the Heavens" for the year 1754; in this the moon's place was calculated with the utmost exactness according to the tables of Dr. Halley for noon and midnight, with the right ascension in seconds of time twice a day. In 1758 he published "A Memoir relating to the Discoveries made in the South Sea, during the Voyages of the English and French round the World." In 1760, Pingrè left France for the island of Rodriguez in the Indian ocean, to observe the transit of Venus that was to take place in the following year, and on the 6th of June of that year he made his observations, from which he concluded that the parallax of the sun was $10''.2$. At the same time the English astronomer Mason concluded from the observations which he made at the Cape of Good Hope, that the parallax was $8''.2$. La Lande, in his "Astronomy," published in 1764, adopted a medium between these conclusions, and supposed the parallax to be $9''$, in which he was followed by astronomers in general, till more numerous observations made on the transit of 1769 led to a different result. After the return of Pingrè from the East, he published a description of Pekin, in which he shewed the position of that capital from the result of a number of calculations of eclipses, and ascertained its longitude, by other calculations, with a degree of precision to which none of the labours of the scientific missionaries had any pretensions. In 1769 he sailed for the island of St. Domingo, on board the Isis man of war, to observe the transit of Venus, and performed the service committed to him in the most able and satisfactory manner possible. An account of this voyage, which proved of considerable importance to the science of geography, as well as astronomy, appeared in 1773, in two vols. 4to. After comparing the results of the immense number of calculations made by the observers of the transit in the year 1769, the sun's parallax has been concluded to be about $8''.6$. (See VENUS, *Transit of*.) In 1771, Pingrè made

made another voyage, on board the *Flora* frigate, with the view of extending the interests of geographical and astronomical knowledge, having with him, as the companion of his pursuits, the chevalier de Borda, a celebrated engineer and geometrician; and the account of their proceedings, observations, and experiments, was published in 1778, in two vols. 4to. In 1784, M. Pingrè published his *Cometography*, or historical and theoretical treatise on Comets, in two vols. 4to., which is his most considerable work, and contains calculations of the orbits of all the comets of which an account has been preserved. After a long life spent in the most important services to the world, he died in the month of May 1796, leaving behind him a high character for integrity, having enjoyed the esteem of the public as well as that of his friends. He was author of many other works besides those that have been already noticed.

PING-TCHAI, in *Geography*, a town of Corea; 40 miles W. of Ou-tchuen.

PING-TCHANG, a town of Corea; 63 miles E. of King-ki-tao.

PINGUAGUEM, a river of Africa, which runs into the Zambeze, S. lat. 18° 10'.

PINGUEDO, in *Anatomy*, the Latin term for fat.

Some restrain pinguedo only to that humid soft kind of fat found in animals, next under the skin. See ADIPS.

PINGUICULA, in *Botany*, the diminutive of *pinguis*, fat, which alludes to a peculiar appearance of greasiness upon the leaves; whence arose the English name of Butterwort, and the French one of *Grassette*, for the plant in question.—Linn. Gen. 13. Schreb. 19. Willd. Sp. Pl. v. 1. 109. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 26. Ait. Hort. Kew. v. 1. 44. Juss. 98. Lamarck Illustr. t. 14. Gært. t. 112.—Class and order, *Diandria Monogynia*. Nat. Ord. *Corydalis*, Linn. according to his own opinion, but we should rather have referred it to his *Personate*; akin to *Lyfimachia*, Juss. rather to his *Pediculares*; the flower agrees best with the latter, the fruit with the former. Its proper place however is in the new order of *Lentibularie*, founded by Richard, and adopted in Brown's Prodr. Nov. Holl. v. 1. 429.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, permanent, ringent; upper lip erect, three-cleft; lower reflexed, divided. *Cor.* of one petal, ringent; its border more or less equally five-cleft. Nectary a spur, elongated from the base of the petal behind. *Stam.* Filaments two, cylindrical, curved upwards, shorter than the calyx; anthers roundish, clapped close to the stigma. *Pist.* Germen superior, globose; style very short; stigma two-lipped, the upper lip larger, flat, reflexed, covering the anthers, the lower very narrow, erect, cloven, shortest. *Peric.* Capsule roundish or ovate, bursting at the top by two valves, with one cell. *Seeds* numerous, cylindrical. *Recept.* central, unconnected.

Eff. Ch. Corolla ringent, spurred. Calyx two-lipped, in five segments. Stigma two-lipped. Capsule superior, of one cell, with many seeds.

1. *P. lusitanica*. Pale Butterwort. Linn. Sp. Pl. 25. Engl. Bot. t. 145. (*P. villosa*; Lightf. Scot. 77. t. 6. *Viola palustris*, *Pinguicula dicta*, *lusitanica*; Griseb. Virid. 84.)—Nectary obtuse, shorter than the nearly regular petal. Flower-stalk hairy. Capsule globose.—Native of Portugal according to Griseb, whose plant we have verified. It is found also on the borders of bogs in Dorsetshire, Hampshire, Devonshire, and Cornwall, as well as in the west of Scotland and Ireland: It is perennial, flowering in June and July. Like all the rest of its genus this herb is desti-

tute of a *stem*, the *leaves* being radical, spreading, ovate, obtuse, viscid, pale with red reticulated veins; their edges involute. *Stalks* several, erect, simple, slightly hairy, three or four inches high, each bearing an elegant little *flower*, whose limb is of a pale lilac, in five nearly equal, emarginate segments, the tube yellow, streaked with red, hairy at the mouth. *Stigma* very unequally two-lipped, concave. *Capsule* exactly 3-lobular. The shape of the part last mentioned affords excellent specific characters in this genus, but is not uniform enough in all to enter into the generic description.

2. *P. crystallina*. Crystalline Butterwort. Sm. Fl. Græc. Sibth. v. 1. 8. t. 11.—Nectary obtuse, shorter than the very irregular six-cleft petal. Segments of the calyx oblong. Flower-stalk smooth at the base.—Gathered by Dr. Sibthorp and Mr. Ferdinand Bauer, in watery places near Camandria, in the isle of Cyprus. Differs from the former in its uniformly glaucous *leaves*, unmarked by red veins, but distinguished by a glandular crystalline clothing like the ice-plant. The *flowers* are similar in colour to *P. lusitanica*, but very different in structure; the segments of their *calyx* being almost linear, not broadly ovate; and the limb of their *corolla* distinctly two-lipped, its upper lip short, in two divaricated lobes, the lower much broader and longer, in three lobes, the middle lobe deeply cloven. The *germen*, and probably the *capsule*, is globose.

3. *P. vulgaris*. Common Butterwort. Linn. Sp. Pl. 25. Fl. Dan. t. 93. Engl. Bot. t. 70. (*P. five Sanicula Eboracensis*; Ger. Em. 788.)—Nectary cylindrical, acute, as long as the very irregular five-cleft petal. Segments of the calyx oblong. Capsule ovate. Common on the bogs of Europe, flowering with us in May and June. Larger than either of the foregoing. The tube and spur of the *corolla* are pale purple, but the limb is deep blue, in five rounded segments, of which the two uppermost are much the smallest, the lower central one the largest, all of them entire. The viscid substance, found on the leaves, is said to be useful to anoint the dugs of cows when sore or injured; at least such is the report of old Gerarde, and hence came the name of Yorkshire Sanicle for this plant.

4. *P. grandiflora*. Large-flowered Butterwort. Willd. n. 3. Decand. Fl. Franc. v. 1. 250. v. 3. 575. Lamarck Dict. v. 3. 22. Illustr. t. 14. f. 2. Engl. Bot. t. 2184.—Nectary cylindrical, acute, as long as the nearly regular, five-cleft, veiny petal. Segments of the calyx ovate, obtuse. Capsule ovate.—Native of France and Ireland. It was discovered by Mr. Drummond, curator of the botanic garden at Cork, in marshy ground in the west part of that county, very abundantly, flowering in May. The *leaves* are nearly twice as large as *P. vulgaris*, which is not found in that neighbourhood. *Flowers* also twice the size of that species, on stronger more viscid *stalks*. *Corolla* much more equally divided, and particularly distinguished by its fine reticulations of dark-blue veins.

5. *P. alpina*. Alpine Butterwort. Linn. Sp. Pl. 25. Fl. Lapp. ed. 2. 11. t. 12. f. 3. Fl. Dan. t. 453. Gunn. Norv. fasc. 2. 71. t. 4. f. 4.—Nectary conical, deflexed, shorter than the tube of the very irregular five-cleft petal. Capsule oblong, beaked.—Native of the alps of Lapland, Switzerland, and Austria, flowering in June, earlier in that country than the *vulgaris*, according to Gunner. It is like that species in foliage, but rather smaller, and essentially different in *spur* and *capsule*. The *corolla* is white, with a yellow palate; its segments very unequal, rounded, undivided.

6. *P. villosa*. Little Hairy Butterwort. Linn. Sp. Pl. 25. Fl. Lapp. ed. 2. 12. t. 12. f. 2. Lapland Tour,

v. 1. 255. v. 2. 109.—Nectary awl-shaped, shorter than the petal. Capsule inversely heart-shaped, compressed. Flower-stalk hairy.—Gathered by Linnæus amongst bog-moss in Lapland, but rarely. It has also been found occasionally in Norway and Siberia. This is much smaller than any of the foregoing, flowering in May or June; the foliage being withered, and seed ripe, by July. The *leaves* are rounded and three-ribbed. *Stalk* slender, straight, finely hairy or downy. *Corolla* pale violet. *Capsule* emarginate. Linnæus originally confounded Ray's synonyms of the *lusitanica* with the present species, which by that means came to be reckoned a British plant.

PINGUIN, a West Indian name, adopted as generic by Dillenius, in Hort. Elth. 320. t. 240. See BROMELIA, n. 4.

PINGUIN, in *Ornithology*, is made a distinct genus of birds, of the order of web-footed, by Mr. Pennant; the characters of which are, that the bill is strong, straight, and bending a little towards the point; the tongue is covered with strong sharp spines, pointing backwards; the wings are very small, pendulous, useless for flight, and covered with mere flat shafts; the body is covered with thick short feathers, with broad shafts, placed as compactly as scales; the legs are short and thick, placed quite behind; the toes are four, standing forward, the interior loose, the rest webbed; and the tail is very stiff, consisting only of broad shafts. He has enumerated and described three species; viz. 1. The Patagonian penguin, which inhabits an isle near the Cape of Good Hope, on the coasts of New Guinea, the isle of Defolation, south of the Cape, the southern parts of America, and the seas among the ice, as high as south lat. $64^{\circ} 12'$, long. $38^{\circ} 14'$ east. It lives much at sea; the wings act as fins; it burrows on land, and is analogous to seals. The name penguin is given to these birds, he says, *propter pinguedinem*, on account of their fatness; and he observes, that it has been corrupted to *penguin*; so that some, imagining it to be a Welch word, signifying *white head*, entertained some hopes of tracing the British colony, said to have migrated into America, under Madoc Gwineth, son of Owen Gwineth, A.D. 1170. But he adds, as the two species of birds that frequent that coast have black heads, we must resign every hope, founded on that hypothesis, of retrieving the Cambrian race in the new world. 2. The lesser penguin, diomedea demersa of Linnæus, or anser Magellanicus of Clusius. And, 3. The red-footed penguin, the phæton demersus of Linnæus, inferior to the last in size, with a thick, arched red bill; plumage like the former in texture; the head, hind part of the neck, and the back, of a dusky purplish hue, and breast and belly white; brown wings, with the tips of the larger feathers white: instead of a tail, a few black bristles; and red legs. It is found on Pinguin isle, near the Cape of Good Hope. Phil. Trans. vol. lviii. art. 14. See ALCA and APTEODYTA.

PINHEIRA *de Azere*, in *Geography*, a town of Portugal, in the province of Beira, on the Mondego; 15 miles S.W. of Viseu.

PINHEL, a town of Portugal, in the province of Beira, situated on a mountain, and fortified; containing six parish churches, and about 1600 inhabitants; seven miles N.E. of Almeida. N. lat. $40^{\circ} 33'$. W. long. $6^{\circ} 44'$.

PINHONES INDICI, the name by which the Portuguese call the purging nuts, as they are called, of America; the fruit of the *jatropha foliis cordatis angulatis* in the Linnæan system, or the *ricinoides* and *curcas* of other writers. It is called Barbadoes nut; and has an oval, walnut-like fruit,

with oblong black seeds. Their taste is sweetish, nauseous, and acrid; and they are powerful evacuants. In America it is said to be taken in considerable quantities, and to purge without much inconvenience. See *PINEI nuclei*, &c.

PINION, in *Mechanics*, an arbor, or spindle, in the body whereof are several notches, into which catch the teeth of a wheel that serves to turn it round.

Or a pinion is a lesser wheel, which plays in the teeth of a larger. See WHEEL.

In a watch, &c. the notches of a pinion (which are commonly 4, 5, 6, 8, &c.) are called *leaves*, and not teeth, as in other wheels.

PINION of Report is that pinion, in a watch, which is commonly fixed on the arbor of a great wheel, and which in old watches used to have but four leaves; it drives the dial-wheel, and carries about the hand.

The quotient, or number of turns, to be laid upon the pinion of report, is found by this proportion: as the beats in one turn of the great wheel are to the beats in an hour; so are the hours of the face of the clock (viz. 12, or 24) to the quotient of the hour-wheel or dial-wheel divided by the pinion of report, that is, by the number of turns which the pinion of report hath in one turn of the dial-wheel; which, in numbers, is $26928 : 20196 :: 12 : 9$.

Or rather thus: as the hours of the watch's going are to the numbers of the turns of the fusee; so are the hours of the face, to the quotient of the pinion of report. If the hours be 12, then $16 : 12 :: 12 : 9$. But if 24, the proportion is $16 : 12 :: 24 : 18$.

This rule may serve to lay the pinion of report or any other wheel, thus: as the beats, in one turn of any wheel, are to the beats in an hour; so are the hours of the face, or dial-plate, of the watch, to the quotient of the dial-wheel, divided by the pinion of report, fixed on the spindle of the aforesaid wheel. See CLOCK and MOVEMENT.

PINION, *Flying*. See FLYING.

To PINION is to bind the hands or arms of a person, so as to prevent his having the free use of them.

PINIROLO, in *Ornithology*, the name of a bird of the tringa kind, somewhat approaching to the sand-piper, but larger; its beak is little more than a finger's breadth long, and black; it is of a mixed chestnut colour, and brown on the back; and its belly and breast are perfectly white: it is common in the Italian markets, and very much resembles the common tringa.

PINITE, in *Mineralogy*, a species of the clay genus, is of a blackish-grey colour, which is frequently covered, on the surface and in rents, with iron ochre. It occurs seldom massive; is almost always crystallized, and that in six-sided prisms, with truncated lateral edges and angles; sometimes the truncating edges are so numerous, that the crystal acquires a roundish aspect. The crystals are frequently middle-sized, sometimes small, and they frequently intersect each other. The external lustre is not at all certain; internally it is glistening, and its lustre is resinous. Its longitudinal fracture is small-grained and uneven; the cross-fracture is imperfect and foliated. The fragments are indifferently angular, sometimes blunt-edged. On the edges it is slightly translucent; it is soft, easily frangible, and not particularly heavy; the specific gravity, according to Kirwan, is 2.98. With regard to its chemical character, it experiences no alteration before the blow-pipe, either alone or with the addition of borax. With carbonate of soda it forms an opaque scoriceous globule; and with microcosmic salt, it makes a transparent opalescent glass. It consists of

Alumine

P I N

Alumine	63.75
Silica	29.50
Oxyd of Iron	6.75

	100.00

It has been hitherto found only in the mine called Pini, at Schneeberg in Saxony, and from the mine it derives its name; it is usually accompanied with quartz, feldspar, and mica.

PINK, in *Botany, Gardening, &c.* See DIANTHUS.

PINK, *Indian*, a species of *ipomoea*; which see.

PINK, *Indian*, is also a species of *lonicera*; which see.

PINK, *Montpelier*. See APHYLLANTHES.

PINK, *Sea*. See THRIFT.

PINK, *Brown*, among *Painters*, is the tinging part of some vegetable of a yellow or orange-colour, precipitated upon the earth of alum, cuttle-fish bone, or some similar calcareous substance. When good, it is a concentrated yellow, which, as a pigment, is transparent in oil, gives the effect of a dark colour, and serves for deep shades. There are many methods of preparing brown pink. One of the best and most common methods is the following: take of the French berries, one pound; of fustic wood in chips, half a pound; and of pearl-ashes, one pound. Boil them in a tin boiler, with a gallon and a half of water, for an hour; and then strain off the tincture through flannel, while the fluid is boiling hot. Having prepared in the mean time a solution of a pound and a half of alum, put it gradually to the tincture, as long as an ebullition shall appear; wash the sediment, as in the preparation of lakes (which see); and when it is brought, by filtering through paper with a linen cloth, to a proper consistence, dry it on boards in square pieces. Or, it may be made without the use of salts, by boiling two pounds of the berries in a gallon of water for two hours, and straining off the tincture through flannel. In the mean time prepare a pound and a half of cuttle-fish bone, by levigating the soft inner part with water on a marble; add this to the tincture, and evaporate them in balneo Mariæ till the matter becomes of a stiff consistence: when the whole has been well mixed by grinding, let it be laid on boards to dry.

The goodness of brown pink must be judged of by its transparency, and force of colour, when mixed with oil; but its qualities of standing well, and not fattening in oil, in both which respects it is commonly defective, can only be ascertained by trial and experience.

PINK, *Dutch*, is a pigment formed of chalk, coloured with the tinging particles of French berries, or other vegetables. It is principally used for coarser purposes in water. It may be made by boiling one pound of French berries, and four ounces of powdered turmeric root in a gallon of water for two hours, and then straining off the tincture through flannel, and boiling it again with an ounce of alum, till it be evaporated to one quart. Prepare in the mean time four pounds of chalk, by washing it over, and afterwards drying it; and mix the chalk with the tincture, by grinding them together, and then dry it on boards. It is sometimes prepared in the same manner with starch and white lead. Its goodness consists in its being of a full gold-coloured yellow, and very bright.

PINK, *English*, is only a lighter and coarser kind of Dutch pink; and may be prepared in the same manner, the quantity of chalk being increased in proportion, as it is intended to be inferior to the Dutch.

PINK, *Light*, is of two kinds; the one being the same with the Dutch pink, only with much less colour, so that

P I N

the proportion of the French berries and turmeric must be lessened to one-half: the other is the same with the brown pink, that is, transparent in oil, but with less colour. It may be prepared by boiling one pound of French berries in a gallon of water, for an hour, and adding to the strained fluid two pounds of pearl-ashes, dissolved and purified, by filtering through paper; then precipitate with alum dissolved in water, by adding the solution gradually, till the ebullition ceases; and proceed as with brown pink.

PINK, *Rose*, is a lake, the earth or basis of which is principally chalk, and the tinging substance is extracted from Brazil or Campeachy wood. This pigment, which does not stand, is seldom employed, except for the coarse work of house-painters, or for paper-hangings, and sometimes with varnish. It may be prepared by boiling six pounds of Brazil wood, or three pounds of Brazil and three of Campeachy wood, in three gallons of water, in which a quarter of a pound of alum has been dissolved, for an hour. Purify the fluid, by straining through flannel, and put back the wood into the boiler with the same quantity of alum, and proceed as before; repeating the operation a third time; mix the three quantities of tincture together, and evaporate them till only two quarts of fluid remain. Prepare eight pounds of chalk, by washing it over in water, in which a pound of alum has been dissolved, and afterwards fusing the chalk from the salt, formed by the alum, and drying it to the consistence of a stiff clay. Grind the chalk and tincture together; and lay the mass to dry out of the sun or cold air. The goodness of rose pink consists chiefly in the brightness of the colour, and fineness of its substance.

PINK, *Pinque, Fr.* in *Sea Language*, is a name given to a ship with a very narrow stern; whence all vessels, however small, whose sterns are fashioned after this manner, are called *pink-sterned*.

Pinks are Mediterranean vessels, which differ from the xebec only in being more lofty, and not sharp in the bottom, as they are vessels of burthen. They have long narrow sterns, and three masts, carrying latteen-sails.

PINKUFELT, in *Geography*, a town of Hungary; 10 miles W. of Steinam Anger.

PINKZOW, a town of Poland, in the palatinate of Sandomirz; 52 miles W. of Sandomirz.

PINNA, or PENNA, a Latin word signifying a feather. It is also used figuratively, in divers arts, to express things which bear some resemblance, in form, to feathers; as the fins of fishes, &c. See FIN.

PINNA, *the Nacre*, in *Conchology*, a genus of the class and order Vermes Testacea. The generic character is; animal a limax; shell bivalve, fragile, upright, gaping at one end, and furnished with a byflus or beard; the hinge is without teeth, the valves are united in one. The inhabitants of these shells produce a large quantity of fine and very strong byflus, which by the Italians is woven into a sort of silk. The shells of all the species, of which there are eighteen, are generally found standing erect in the smoother waters of the bays, with the larger end a little open. The fish of many of them are highly esteemed as food.

Species.

RUDIS. Shell vaulted, with arched scales arranged in rows. There is a variety: the *first* inhabits the American and Atlantic oceans, is from twelve to sixteen inches long, and from four and a half to eight broad; the shell is red, and it has from six to eight grooves. The *second* is found in the Indian and Red seas; it is black, with scarcely any visible grooves.

PECTINATA. Shell longitudinally striate half way; one

side slightly wrinkled transversely. There is a variety of this species. They are both found in the Indian ocean; the *first* is about three inches long and four broad; the shell is triangular, horny. The *second* is four and a half inches long, two and a half broad, thinner and more rare.

NOBILIS. Shell striate, with scales. There are four varieties of this species. They are found in the Mediterranean, Adriatic, and American seas. The shell of this species is seven inches and a half long, and three and a half broad: it is brown, the exterior margin rounded; the scales are larger towards the edges, and near half an inch long; one-half of the valves is ribbed, the other has transverse wrinkles, which at the broader part are crossed with striae.

* **MURICATA.** Shell striate, with concave, ovate, acute scales. This is described and figured in Mr. Donovan's British Shells; it is the *P. fragilis* of Pennant. It is a native of the European and Indian seas, is from three to nine inches long, and one-third as broad; the shell is thin, brittle, pellucid, and horny; the outside is formed with longitudinal ribs, rough with rows of small prickles.

ROTUNDATA. Shell with obsolete scales, the margin rounded. It inhabits the Mediterranean; it is sometimes above two feet long; the shell is oblong, whitish, with perpendicular, undulate, parallel wrinkles, and very fine, concave, acute, scattered scales on the broader part.

SQUAMOSA. Shell with very fine undulate scales, and flexuous broad wrinkles; the smaller end is pointed and naked. It inhabits the Mediterranean, is about thirteen inches long, and half as broad. In colour it is a little chestnut at the larger end, and whitish at the smaller one; the external margin is angular.

CARNEA. Shell thin, flesh colour, naked, longitudinally grooved; the external margin is acute and rounded. Its habitation is not known; it is sometimes varied with white spots.

SUCCATA. Shell smooth, fatchel-shaped, and a little erect. It inhabits the Mediterranean and Indian seas; is five and a half inches long, and half as broad; the shell is thin, above it is reddish, beneath whitish, above flat, with a rounded margin, beneath gibbous, without scales, but marked with ten broadish, longitudinal striae.

DIGITIFORMIS. Shell smooth, tubular, finger-shaped, incurved, the extreme margin membranaceous. It is a native of India. The shell is flattish, oblong, and pellucid.

LOBATA. Shell naked, lobed. Found in India. The shell is of a straw colour, with purple striae, membranaceous and heart-shaped when the valves are open. The lateral lobes rounded and broader, with a sort of nerve from the hinge to the lobes, and from the nerve there are lateral lines.

VITREA. The shell of this species is hyaline, with longitudinal striae, the striae with a few scales, are crossed by other transverse striae at the margin. It inhabits the Indian ocean, but is very rare.

INCUROA. Shell narrow, long, naked, carinate, with transverse undulate wrinkles. It inhabits the Indian ocean; pale horn colour, curved at the hinge, and marked with a few longitudinal striae.

BICOLOR. Shell thin, inflected at the lateral margin, yellowish, with black-brown rays; with a few longitudinal striae. It inhabits the Red sea. It is of a horn colour, long, with a few transverse curved striae at the margin, the larger end is rounded.

EXUSTA. Shell flattish, horny, with blackish rays, spots, and clouds, and many smooth striae. It is rare, but sometimes found in the southern ocean of India.

VEXILLUM. Shell truncate at the outer margin, dilated, naked, horny, with a few black clouds; longitudinally striate on the fore-part, and transversely wrinkled behind. It inhabits India, and is extremely rare. The shell appears as if it were winged, with a curved lateral margin.

PAPYRACEA. Shell very thin, brittle, horny, with longitudinal ribs, the extreme margin roundish. This is a native of the Indian ocean: the back of the ribs is sometimes scaly; in the middle of the shell is a violet-brown spot, and a few transverse wrinkles at the lateral margin.

SANGUINEA. Shell flattish, and slightly incurved: it is red, with a few perpendicular smooth striae. The shell is three inches long: it is probably a variety only of some other species.

BULLATA. The shell of this species is very straight, thin and perpendicularly striate, with transverse spinous wrinkles at the lower margin. This, like the last, is thought not to be a distinct species.

PINNA Auris, in *Anatomy*. See **EAR**.

PINNA Nasi, is the same as *ala nasi*. See **NOSE**.

PINNACE, a small vessel, navigated with sails and oars, and carrying generally two masts; chiefly used as a scout for intelligence, and for landing of men.

One of the boats belonging to a great man of war, serving to carry the officers to and from the shore, is also called the pinnace. It resembles a barge, but never rows more than eight oars, whereas a barge properly never rows less than ten. Pinnaces are for the accommodation of lieutenants, &c. as barges are for admirals, and captains of ships of war.

PINNACLE, from *pinna*, or *pinnaeculum*, in *Architecture*, the top or roof of a house, terminating in a point.

This kind of roof among the ancients, was appropriated to temples; their ordinary roofs were all flat, or made in the platform-way.

It was from the pinnacle, that the form of the pediment took its rise.

* **PINNACLE Island**, in *Geography*, an island in the North Pacific ocean, so named by Capt. Cook from the termination of its elevated summit in several pinnacle rocks. N. lat. 60° 25'. E. long. 186° 40'.

PINNACLE Point, a cape on the S.E. coast of Alaska, so called by Capt. Cook in 1778. N. lat. 55° 10'. E. long. 198° 5'.

PINNACLE Islands, two small Japanese islands. N. lat. 29° 52'. E. long. 132°.

PINNÆ, Aculei Pinnarum, in *Ichthyology*. Every apophysis, or eminence on the head or body of a fish, which is so sharp at the end as to be capable of pricking, is called an aculeus; but the aculei pinnarum in particular are those prickly radii or bones, which serve to support the fins; and being carried out beyond the rim of the membrane, end in so many points.

These aculei are simple cylindric officles; whereas the other officles, which sustain the fins, are less rigid, and are bent and not prickly; and these are not simple, but are composed each of two officles, closely cohering one to another. Many of these radii are divaricated at their extremity into two, three, or more branches; these, when they are carried out beyond the rim of the membrane, are harmless, and are seen to be composed of two officles, as the body of the radius is. The aculei of the back and belly of all fishes are so far of the same nature, that they never stand single, as some have supposed them to do in particular instances; but they are always connected one to the other at the bottom by a membrane, though that be ever so small and low, as in some it is scarcely visible. See *Anatomy of FISH*.

PINNA-

PINNAMQUAM, in *Geography*, a small stream in Washington county, and state of Maine, which gives name to a new settlement.

PINNARUM Dilator Proprius, in *Anatomy*, a name given by Santorini to one of the muscles of the face, which he has also called myrtiformis nasi, and which Cowper has called depressor labii superioris, five constrictor aë nasi, and Albius the depressor aë nasi.

PINNARUM Radii. See **RADI** *Pinnarum*.

PINNATED LEAF, among *Botanists*. See **LEAF**.

PINNATIFID LEAF. See **LEAF**.

PINNATIPEDES, or *Fin-footed Birds*, in *Ornithology*, an order of birds, the characters of which are; that the bill, body, and mode of life resemble those of the waders or gallæ; the thighs are likewise naked for the lower half, and the feet are fitted for wading in marshes, all the toes being divided; but the toes are edged on each side with a membrane for their whole length. These birds mostly live in pairs while breeding, and construct very large nests of various leaves and grass in their marshy haunts. The genera are *Phalaropus*, *Fulica*, and *Podiceps*; which see.

PINNATUS, in *Heraldry*, a term used by the Latin writers on these subjects, to express that sort of line in arms which is called by our heralds the embattled *line*, or *crenelle*. It is also called by some *linea pinnis asperata*, and by Sylvester Petro Sancto *murales pinnule*. When this line is only embattled on one side, it is properly expressed by this word; but when it is embattled on both sides, as in some arms, it is called *breteffe*, and *contre breteffe*.

PINNAW, in *Geography*, a river which runs into the Elbe; 20 miles below Hamburg.

PINNE, a town of the duchy of Warsaw; 24 miles W. of Posen.

PINNEBERG, a town of the duchy of Holstein, capital of a lordship; eight miles N.W. of Hamburg. N. lat. 53° 43'. E. long. 9° 54'.

PINNEYRAH, a town of Hindoostan; 12 miles N.N.W. of Benares.

PINNING, in *Building*, the fastening of tiles together, with pins of heart of oak; for the covering of a house, &c.

PINNIRAPI, in *Antiquity*, an order of gladiators, who being matched with the Samnites, used to catch at the pinnæ which adorned their helmets, and bear them off in triumph, as marks of victory.

PINNOW, in *Geography*, a town of Hinder Pomerania; six miles N.E. of Plate.—Also, a lake of Brandenburg, in the Middle Mark, near Oranienburg.

PINOLA, or **PINGOLA**, a town of Mexico, in the province of Guatimala; 75 miles E. of Guatimala.

PINOLS, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Brioude. The place contains 747, and the canton 3580 inhabitants, on a territory of 210 kilometres; in nine communes.

PINOS, a town of Spain, in the province of Grenada; five miles E. of Grenada.—Also, an island near the S. coast of Cuba, resembling a horse-shoe in its figure, about 75 miles in circuit, mountainous and covered with pines. N. lat. 21° 32'. W. long. 82. 10'.

PINOS. See **PINES**.

PINOSA, a town of the island of May.

PINSHOWITZ, a town of Bohemia, in the circle of Leitmeritz; seven miles S. of Auffig.

PINSK, a town of Russian Lithuania, in the palatinate of Brzesc, surrounded by morasses. Jews are numerous, and the Greeks have a bishop; the chief manufacture is

that of dressing Russian leather; 84 miles E. of Brzesc. N. lat. 52° 12'. E. long. 25° 53'.

PINSSON, FRANCIS, in *Biography*, a learned jurist, son of a professor of law of the same name, was born at Bourges in 1612. He was admitted an advocate in the parliament of Paris in 1633; but he was particularly distinguished for his great knowledge of the law of benefices, in which he was regarded as the oracle, and which he illustrated by several learned works. Of these were "Traité des Benefices;" "La Pragmatique Sanction de St. Louis, et celle de Charles VII. avec Commentaires;" "Notes sommaires sur les Indults accordés à Louis XIV. &c.;" "Traité des Regales," 2 vols. 4to. which is said to be a very learned and useful performance. This industrious writer died at Paris in 1691. Moreri.

PINT, PINTA, a vessel or measure used in estimating the quantity of liquids, and even sometimes of dry things.

Budæus derives the word pint from the Greek *πινθα*; others from the German *pint*, a little measure of wine; Nicod from the Greek *πινειν*, to drink.

The English pint is three-fold; the one for wine measure, another for beer and ale measure, and a third for dry measure.

The wine pint is said to contain a full pound, avoirdupois, of common running water; two pints make a quart, two quarts a pottle, two pottles a gallon, &c.; a hoghead is $8\frac{2}{3}$ cubic feet; a gallon 231 cubic inches; and a pint $28\frac{2}{3}$ cubic inches. See **MEASURE**, and **TUN**.

In the English ale and beer measure, the pint is the eighth part of a gallon, or 282 cubic inches; consequently contains $35\frac{1}{4}$ cubical inches. See **GALLON**.

As to the pint used in Scotland, there are different opinions concerning the number of cubical inches it contains. Dr. Gregory makes them 109; others, from several careful mensurations of the standard kept at Edinburgh, make the Scotch pint to contain $103\frac{2}{3}$; and those in common use are said to contain betwixt 105 and 106 cubical inches. Another experiment was made with a cask, which was found to contain $46\frac{2}{3}$ Scotch pints, and $18\frac{1}{2}$ English ale gallons. Supposing this mensuration just, the Scotch pint will be to the English ale gallon as 289 to 750; and if the English ale gallon be supposed to contain 282 cubical inches, the Scotch pint will contain 108.664 such inches. The Scotch pint, according to the standard sterling jug, is 103.404 English cubic inches: hence 105 Scotch pints = 47 English wine gallons, and 11 Scotch pints = 6 English ale gallons. The Scotch quart is commonly reckoned about $\frac{1}{10}$ th less than the English wine gallon, and about $\frac{1}{4}$ th less than the English ale gallon; and 1 pint = 2 choppins; and 1 choppin = 2 mutchkins; and 1 mutchkin = 4 gills. See **MEASURE**.

The Paris pint, according to the old system, is estimated at one-sixth of the ancient congius, and contains two pounds of common water, and is therefore nearly equal to an English wine quart; it is divided into chopines, which some call septiers; the septier into two demi-septiers; the demi-septier into two poissions, each poission containing six cubic inches. Two pints make a quart, quarteau, which some call a pot: the pint of St. Denis is almost double that of Paris. See **MUID**.

At Genoa 100 pinte, wine measure, are equal to 2 barrili = a mezzarola = about 39 English gallons. For a comparison of the liquid, &c. measures of different countries, see **MEASURE**.

PINTADO, or *Afra avis*, in *Ornithology*, a name given by the ancient Roman authors to the Guinea-hen. See **NUMIDA**; see also **PROCELLARIA Capensis**.

PIN-TAIL, or *Anas Acuta*. See DUCK.

PINTARD'S SOUND, in *Geography*, a bay on the W. coast of North America, the mouth of which extends from cape Scott on the southern side, in N. lat. $50^{\circ} 56'$, and W. long. $128^{\circ} 57'$, to Point Disappointment, in N. lat. $52^{\circ} 5'$, and W. long. $128^{\circ} 50'$: it contains many small islands.

PINTCHLUCO RIVER, a large branch of the Chata Uche, the upper part of Appalachian river.

PINTLE, in *Artillery*, a long iron bolt, fixed upon the middle of the limber bolter, to go through the hole made in the trail-transom of a field carriage, when it is to be transported from one place to another. The hole through which the pintle passes is wider above than below, in order to leave room for the pintle to play in.

PINTLE-Plate, is a flat iron, through which the pintle passes, and nailed to both sides of the bolter, with eight diamond-headed nails.

PINTLE-Washer, an iron ring, through which the pintle passes, placed close to the bolter for the trail to move upon.

PINTLE, *Priest's*, in *Botany*. See WAKE Robin.

PINTLES, in *Ship Building*, straps of mixed metal or iron, fastened on the rudder in the same manner as the braces on the stern-post, into which they hang the rudder by a stout pin or hook at the fore end: thus the rudder turns or traverses as upon hinges, from side to side. Sometimes one or two are shorter than the rest, and work in a socket-brace, whereby the rudder turns easier. The latter are called *dumb-pintles*.

PINTO, THOMAS, in *Biography*, an excellent performer on the violin, born in England of Italian parents. He was a miraculous player on his instrument when a boy; and long before manhood came on, was employed as the leader of large bands in concerts. He was, however, when Giardini arrived in England, very idle, and inclined more to the fine gentleman than the musical student; kept a horse; was always in boots of a morning, with a switch in his hand instead of a fiddle-stick. But after hearing Giardini, who was superior to all other performers on his instrument with which he was acquainted, he began to think it necessary to practise, which he did for some time with great diligence. With a powerful hand, and marvellous quick eye, he was in general so careless a player, that he performed the most difficult music that could be set before him, better the first time he saw it, than ever after. He was then obliged to look at the notes with some care and attention; but, afterwards trusting to his memory, he frequently committed mistakes, and missed the expression of passages, which, if he had thought worth looking at, he would have executed with certainty. After leading at the opera, whenever Giardini laid down the truncheon, he was engaged as first violin at Drury-lane theatre, where he led during many years. He married for his first wife Sybilla, a German under-singer at the opera, and sometimes employed in burlettas at Drury-lane. After her decease, he married the celebrated Miss Brent, and, quitting England, settled in Ireland, where he died in December 1782, aged 53 years.

His accuracy in playing at sight was so extraordinary, that he even astonished Bach and Abel by the extent of this faculty; and to embarrass him, if possible, they composed jointly a concerto for the violin, with solo parts as difficult as they could invent; and, carrying it to Vauxhall as soon as transcribed in separate parts, told him that they had just finished a concerto, of which, as it was somewhat out of the common way, they wished to hear the effects, if he would venture to try it at sight. "Let me see it," says Pinto; and after a slight glance at the solo parts, and

picking his teeth in his usual way, he said if they pleased he would try it as his concerto for the night. And the eminent composers who wished to make this experiment, declared that they did not believe any of the greatest performers in Europe on the violin, would have played it better with a month's practice.

Pinto, who in playing an adagio seemed to have so much feeling and expression, was a Stoic at heart, equally indifferent to pain and pleasure. While he led the band at Drury-lane, during the most affecting scene of Garrick's capital tragic parts, he used to fall asleep in the orchestra full in his view, which, after our *genuine* Roscius had with indignation seen, he never rested till his place in the orchestra was supplied with a leader on whose feelings he had more power. Indeed, we remember a more ridiculous mortification happening to our ever-to-be-lamented friend, Garrick, from a sentinel at one of the stage doors, equally destitute of human feelings with Pinto, yawning aloud during the deepest distress of king Lear, which so completely turned "what should be great, to farce," that the vulgar part of the audience, being cocknies, burst into a loud *horse-laugh*; which so disconcerted and enraged the good old king, that he complained to the captain of the guard, and begged that so impenetrable a sentinel might never be placed again on the stage to make the audience laugh, whilst he was doing every thing in his power to make them cry.

Pinto died with the same indifference about worldly concerns as he had lived, and left his unfortunate widow, the once much famed Miss Brent, so literally a beggar, that she returned to England to solicit charity from the Musical Fund; which, alas! she did in vain: for by his having during several years neglected to pay his subscription, all her claims were annihilated in an establishment which she and her husband had often by their gratuitous performance contributed, at its annual benefits, to support, previous to its being enriched, and rendered a royal institution by the commemoration of Handel.

PINTO, in *Geography*, a town of Spain, in New Castile; 9 miles S. of Madrid.

PINTRAL, a town of Hindoostan, in the Carnatic; 26 miles S. of Ongole.

PINTURICCIO, BERNARDINO, in *Biography*, was born at Perugia in 1454, and was a disciple, and for some years associate, of Pietro Perugino. He painted in history and portraits, and was in so much esteem, that he was employed to paint the portraits of pope Pius II., and of Innocent VIII; of Giulia Farnese, Cæsar Borgia, and queen Isabella of Spain. His style, nevertheless, was extremely dry and Gothic, as he introduced gilding in the architectural and other parts of his pictures, and an over-laboured degree of finishing.

In his most memorable performance, the history of Pius II., painted in ten compartments in the library at Sienna, he is said to have been assisted by Raphael, then a very young man, and pupil of Perugino, who made some cartoons of the most material incidents, and sketched many parts of the compositions.

His last work was a Nativity for the monastery of St. Francis at Sienna; in which place he had a room assigned him to paint in, without the danger of his being interrupted; and out of which he requested every thing might be removed. Willing to indulge him, the monks caused all the furniture to be taken away, except an old chest, which, being greatly decayed, they did not attempt to move, as they were fearful of destroying it. Pinturiccio insisted, however, upon its removal; and the attempt was scarcely

scarcely made, when it broke to pieces, and a treasure of 500 pieces of gold was discovered concealed within it.

The joy of the monks was equalled only by the mortification of the painter, who was said to have died of chagrin soon after, at the age of 59.

PINTZOUA, in *Geography*, a town of Prussia, in the province of Pomerelia; 22 miles S.S.W. of Marienburg.

PINUS, in *Botany*, the fir, cedar, larch, &c. a most important and well-known genus of plants, two points in whose history have, nevertheless, been involved in great obscurity; these are the derivation of the generic name, and the nature and situation of the stigma of the flower. Linnæus places *Pinus* amongst ancient Latin names of unknown origin; and Martyn, like Ambrosinus, leaves it unexplained. The lexicographers are mostly content to refer to its Greek synonym *πίναξ*; and it is possible that both words had the same source. De Theis deduces *Pinus*, very satisfactorily, from the Celtic, and shews it to exist, variously modified, in all the dialects of that ancient language, its basis being *pin* or *pen*, a mountain or rock; whence we have the Apennines; the Pennine Alps, &c. The Gallic *pinawidden*, like the German *pyn-baum*, means precisely a mountain tree; than which nothing can be more appropriate. Of the stigma we shall treat in its proper place.—Linn. Gen. 499. Schreb. 651. Willd. Sp. Pl. v. 4. 494. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1031. Ait. Hort. Kew. v. 5. 314. Juss. 414. Tourn. t. 355, 356. Lamarck Illustr. t. 786. Michaux Boreal-Amer. v. 2. 204. Pursh North Amer. v. 2. 639. Gærtn. t. 91. (*Abies*; Juss. 414. Tourn. t. 353, 354. Lamarck Illustr. t. 785. Larix; Tourn. t. 357.)—Class and order, *Monococia Monadelphica*. Nat. Ord. *Conifera*, Linn. Juss.

Gen. Ch. Male, *Cal.* none, except the spreading scales of the flower-bud. *Cor.* none. *Stam.* Filaments very numerous, collected below into a cylindrical column, racemose above; anthers horizontal, wedge-shaped, opening underneath by two longitudinal cells, and crowned by an ascending membranous crest.

Female, on the same plant. *Cal.* a nearly ovate dense catkin, composed of oblong, closely imbricated, wedge-shaped, rigid, permanent, two-lipped scales. *Cor.* none. *Pist.* Germens two at the base of each scale; style none; stigmas between the lips of the scale. *Peric.* none, except the hardened scales, combining to form a woody permanent cone. *Seeds* two to each scale, each lodged in a little hollow at the base, oval, furnished with a vertical, membranous, unequal-sided wing, usually larger than the seed, but smaller than the corresponding half of the annexed scale.

Eff. Ch. Male, Calyx none. Corolla none. Anthers racemose, crested.

Female, Calyx the scale of a catkin, unequally two-lipped. Corolla none. Cone woody. Seeds two, winged at the base of each scale.

Obs. Linnæus describes as the style and stigma, the awl-shaped point, which terminates one lip of the scales of the female catkin, and, in some species, hardens into a very powerful spine. Jussieu describes in his *Abies*, which includes the larches and spruce firs, two glands like stigmas at the base of one of the scales, or rather, as we understand the flower, one of the lips of each scale. An examination of several species has persuaded us that the impregnation takes place nearly as this great writer's account implies, and possibly, in some measure, as Mr. Salisbury has explained, in Tr. of the Linn. Soc. v. 8. 309; though we suspect some error as to the Larch, and particularly those "long crimson stigmas" of the *P. Cembra*, there described.—The knowledge of the species of this genus, and their

various useful properties, has been greatly augmented by the magnificent and learned monograph of Mr. Lambert, published in 1803. Linnæus has defined but twelve species; Mr. Lambert describes thirty-four, of which thirty are enumerated by Mr. Aiton in the new edition of his *Hortus Kewensis*; Mr. Pursh has nineteen in his *Flora of North America*, just come to our hands. Those which are the produce of that country have received the most complete botanical investigation. The oriental ones are not, as yet, so well understood, nor are they, apparently, by far so numerous.—The younger Michaux in his *Arbres forestiers*, a work in three volumes 8vo., has, it seems, criticised inaccurately much of Mr. Lambert's work, and very unwarrantably changed some of his names. These attacks are repelled by our intelligent friend, in Mr. Pursh's work, published under his inspection. Our sections are those of Mr. Lambert.

Sect. 1. *Leaves several from the same sheathing base.* PINUS of Tournefort. Nineteen species.

1. *P. sylvestris*. Scotch Fir. Linn. Sp. Pl. 1418. Willd. n. 1. Ait. n. 1. Lambert 1. t. 1. Engl. Bot. t. 2460. Mill. Illustr. t. 82. Woodv. Med. Bot. t. 207. Ger. Em. 1356.—Leaves in pairs, rigid. Young cones stalked, recurved. Crest of the anthers very small.—Native of dry stony sandy hills in Scotland, and other northern parts of Europe, flowering in May, and ripening seed two years afterwards. This species lives to the age of 400 years or more, and is lofty and straight in its growth, with oblique branches. The bark scales off in large light cellular flakes. *Sheaths* of the leaves spirally disposed, tubular, membranous, at length rugged, torn at the end. *Leaves* in pairs from each sheath, equal, about two inches long, linear, narrow, obtuse with a small point, minutely serrated, evergreen, smooth; their upper surfaces, which are dark green, and rather concave, originally clasped together, but soon separating; the under convex, more glaucous, striated. *Flowers* terminal, erect; the males aggregate, spiked, sulphur-coloured, soon surmounted by a protruding leafy branch, each flower having several chaffy concave scaly bracteas at its base, which some call a four-leaved calyx: females solitary, globular, variegated with purple and green, with several serrated, pointed, scaly bracteas. The year after impregnation, the young fruit becomes lateral, stalked and reflexed, green, of a more ovate figure; and the second year ripens into ovate, pointed, hard, tessellated but unarmed, woody cones, whose dry scales finally gape, and allow of the dispersion of the winged seeds. This is further promoted, in various species, by the attacks of *Loxia*, and such hard-billed birds, who in seeking the seeds for food, split the cone, thus dispersing many more seeds than they devour. The wood of *P. sylvestris* is known by the name of red deal, and its value, as well as that of the tar, pitch, and turpentine, afforded by this species, is well known. The tree is planted on our most barren exposed hills and downs, as a shelter for more tender plantations, and is in itself a profitable object of culture, though not one of the most agreeable ornaments to a country where any thing else will grow. We have observed with regret some noble beech woods in Berkshire, recently bordered with miserable Scotch and spruce firs, which happily indeed soon die in that chalky soil, and the mischief is neither lasting nor extensive.

P. Mugbus, Jacq. Ic. Rar. t. 193. Willd. n. 2, is judged by Mr. Lambert to be a variety of *sylvestris*, of a humble spreading growth, caused probably by its lofty station on the alps of Austria; nor is it, as Jacquain thought, the *Mugbus* of Scopoli; see the next species.

2. *P. Pumilio*. Mugho, or Mountain Pine-tree. Willd.

n. 3. Ait. n. 2. Scop. Carn. v. 2. 247. Lamb. 5. t. 2. (*Pinaster Pumilio*; Cluf. Pann. 15. *P. quartus austriacus*; Cluf. Hist. v. 1. 32. Ger. Em. 1358.)—Leaves in pairs, short, straight. Cones ovate, obtuse, very small; the younger ones sessile, erect. Crest of the anthers prominent, cloven.—Native of mountains in the south-east parts of Europe, flowering in June. Mr. Blackburne of Orford is recorded as its first cultivator in England. This, the most humble of its genus, is scarcely seven feet high, extending itself by trailing *shoots*, and even by rooting decumbent *branches*. The *leaves* are shorter, and *cones* much smaller than the foregoing, and the much more distinct, prominent, two-lobed, crenate crest of the *anthers*, affords a satisfactory mark of specific distinction.

3. *P. pungens*. Prickly-coned Pine-tree. Lamb. 91. t. 16. f. 6, the cone only. Ait. n. 3. Pursh. n. 14. Mich. Arb. For. v. 1. 61. t. 5. Ait.—Leaves in pairs, short, acute. Cones ovate; the prickles of their scales elongated, very sharp, incurved; the lower ones deflexed.—Native of the summits of the blue mountains on the frontiers of Virginia and North Carolina, in large forests, where it was found by W. Strickland, esq. The *leaves* are much broader and shorter than those of *P. Pumilio*, and tipped with a spinous point. *Cones* broad-ovate, light tawny brown, armed with extremely pungent incurved spines.

4. *P. Banksiana*. Labrador Pine-tree. Lamb. 7. t. 3. Ait. n. 4. Willd. n. 10. Pursh n. 10.—Leaves in pairs, divaricated, oblique. Cones recurved, twisted. Crest of the anthers dilated, emarginate.—Native of Nova Scotia, Hudson's Bay, &c. Rarely cultivated in England, flowering in April. This is with us a tall *tree*, with numerous long and spreading *branches*, though more humble on its native rocks. *Leaves* scarcely above an inch long, variously twisted. Crest rather broader than the *anther* itself, kidney-shaped, emarginate and crenate. *Cones* very abundant, oblong, rather slender, rugged, brown, two inches in length, recurved, so that their points touch the branch, and often meet each other. Communicated to Mr. Lambert by Sir J. Banks. The finest trees of this species are in the gardens at Pain's-hill and Kew.

5. *P. Pinaster*. Cluster Pine-tree. Ait. H. Kew. ed. 1. v. 3. 367. Lamb. 9. t. 4, 5. Ait. n. 5. Willd. n. 4. (*P. maritima altera*; Matth. Valgr. v. 1. 91. Duham. Arb. v. 2. 125. t. 29.)—Leaves in pairs, elongated. Cones whorled, clustered, ovate, sessile, drooping, with somewhat pointed scales. Crest of the anther rounded.—Native of the south of Europe, in rocky mountainous places, especially near the sea. Common in English plantations, flowering in April and May. Larger in every part than the Scotch fir, forming a stout and lofty *tree*. The *leaves* are four inches long, narrow, pungent, straight. The male *flowers* compose a very handsome golden thyrus; the crest of their *anthers* is rounded, nearly orbicular, crenate; not *dilated*, as Willdenow has erroneously copied Mr. Lambert, which has caused a similar error in Hort. Kew. Female *flowers* with rich crimson scales. *Cones* ovate, rather pointed, four inches long, bright brown, each scale tipped with a short broad bluntish spine. In the south of France these trees are wastefully cut all down one side, as they stand, in winter, for the turpentine to ooze out. The wood and pitch is much used in Switzerland. The stakes serve to support vines of humble growth.

6. *P. Pinca*. Stone Pine-tree. Linn. Sp. Pl. 1419. Lamb. 11. t. 6, 7, 8. Willd. n. 11. Ait. n. 6. (*P. domestica*; Matth. Valgr. v. 1. 87. *P. fativa*; Duham. Arb. v. 2. 125. t. 27. Ger. Em. 1355.)—Leaves in pairs. Cones ovate, obtuse, as long as the leaves; their scales with

recurved deciduous points. Seeds bony, with very short wings. Crest of the anthers jagged.—Native of the south of Europe and north of Africa. Mr. Hawkins and Dr. Sibthorp observed it in Greece, especially in the sandy plains of Elis, from whence the nuts are exported for eating, and the timber is often used for ship-building. In Italy these nuts generally supply the place of almonds, in various articles of cookery; and that they have done so from remote antiquity, appears from their having been found among the domestic stores in the pantries of Herculaneum and Pompeia. The kernel is sweet, with a turpentine flavour; its shell very hard. This *tree* appears to great advantage in the landscapes and gardens about Rome, as well as occasionally in our English plantations. Its fine dark green *leaves*, copious male *bloffoms* diffusing a shower of sulphureous pollen on all the neighbouring plants, and the massy *cones*, render it very remarkable.

7. *P. maritima*. Maritime Pine-tree. Lamb. 13. t. 10. Willd. n. 8. Ait. n. 7.—Leaves in pairs, slender, rough-edged. Cones ovate, solitary, drooping, stalked, tessellated, even, close. Crest of the anthers somewhat pointed, undivided.—Native of the sea-coasts of the south of Europe. Micheli sent a specimen to Sherard from Italy, and Dr. Sibthorp gathered the same in Greece, as we learn from his collection of drawings. Miller appears to have cultivated this species, but we feel some slight doubts respecting Mr. Lambert's ninth plate, and his cone from Sion gardens, t. 10. f. f, is surely different. The *cones* of the true *maritima* are peculiar for their even or level surface, the outer part of each scale being flat, with a central scar, which has no point nor prominence; nor do they spread or separate much to discharge the seeds. The male *flowers* are capitate, not spiked; they are shorter and the crest of their *anthers* less orbicular, and more pointed, in Dr. Sibthorp's figure than in Mr. Lambert's t. 9, though both drawings were made by the same excellent artist; and their capitate inflorescence agrees.

8. *P. halepensis*. Aleppo Pine-tree. Lamb. 15. t. 11. Willd. n. 7. Ait. n. 8. Desfont. Atlant. v. 2. 352. Mill. Ic. t. 208. (*P. maritima prima*; Matth. Valgr. v. 1. 90.)—Leaves in pairs, very slender. Cones ovate-oblong, drooping, stalked, tuberculated, polished, unarmed. Crest of the anthers rounded, jagged.—Native of Syria. Observed by Desfontaines also on mount Atlas, and on the uncultivated hills of Barbary, abundantly, as well as in the south of France near Frejus; but this tree does not always bear the winters of Paris nor of London, so that it is very scarce in collections. It differs from the last in having more slender *leaves*; spiked male *flowers*, the crest of whose *anthers* is broader than long, jagged, not pointed; and especially in the ruggedness of its cones, the prominent part of whose scales is tumid, and of a fine polished red-brown. These scales spread widely to discharge the seeds. The synonym of Matthioli is given on the authority of a specimen seen by Mr. Lambert in the Sherardian herbarium; and indeed his cut answers well to our plant, though employed by Duhamel, v. 2. t. 28, for his own *P. maritima major*, instead of his *P. hierosolymitana*, &c. n. 14, to which we presume it belongs.

9. *P. Massoniana*. Indian Pine-tree. Lamb. 17. t. 12. Willd. n. 9.—Leaves in pairs, very long and slender; their sheaths very short. Crest of the anthers short, broad, toothed.—Native of China; from whence its seeds were brought to the Cape of Good Hope, and produced flowering trees there, specimens of which, given to Sir J. Banks by Mr. Masson, were examined and delineated for Mr. Lambert's work, nor has this species been elsewhere published.

PINUS.

lished. The *stipulæ* on the young shoots are finely fringed. *Leaves* four or five inches long, apparently erect. Male *flowers* spiked; the creft of their *anthers* twice as broad as long, sharply toothed. The *cones* have not come to our knowledge.

10. *P. inops*. Jersey Pine-tree. Ait. Hort. Kew. ed. 1. v. 3. 367. Lamb. 18. t. 13. Willd. n. 5. Ait. n. 9. Pursh. n. 8. Michaux Arb. For. v. 1. 58. t. 4.—Leaves in pairs. Cones drooping, oblong-conical, longer than the leaves; their scales with awl-shaped prominent spines. Crest of the anthers short, broad, jagged.—Native of dry barren hills, in the interior parts of North America, from New Jersey to Carolina, where it blossoms in May. Mr. Pursh says it is of a middle size, straggling growth, and full of resin, the branches tougher than any other pine with which he is acquainted. It might serve for several useful purposes, if the wood were not so liable to early decay. This account agrees with Mr. Lambert's, which M. Michaux has controverted. Kalm has remarked that cattle in hot weather studiously single out this tree for shade in preference to all others. Its effluvia are supposed to be agreeable to them; or rather perhaps hostile to some insects which persecute them, such as gad-flies, to whose approach all cattle are extremely sensible. See Linn. Tour in Lapland, v. 1. 205. The *leaves* of *P. inops* are of a dark green, two inches long, less slender than in *maritima* or *halepensis*, the aspect of the tree being most like a starved Scotch Fir. The scales of the female *catkin* are reddish, with long taper points, that harden into pungent, prominent, slightly curved spines on the ripe *cone*.

11. *P. resinosa*. American Pitch Pine-tree. Red Pine. Ait. H. Kew. ed. 1. v. 3. 367. Lamb. 20. t. 14. Willd. n. 6. Ait. n. 10. Pursh n. 9. (*P. rubra*; Michaux Arb. For. v. 1. 45. t. 1.)—Leaves in pairs, elongated, with long sheaths. Cones ovate, sessile, nearly solitary, tolerably even, unarmed, not half the length of the leaves. Crest short, jagged, narrower than the anther.—Native of Canada and the western parts of New York. *Pursh*. It was first raised in England by the late duke of Northumberland, at Sion House, where many of this species are still to be seen, flowering in May. This tree requires, according to Mr. Lambert, a moist situation, and light sandy soil, and though rare in England, is well worthy of cultivation, being of elegant appearance, and remarkable for the fragrance and abundance of its resin. The *leaves* are four inches long, roughish at the point, spreading, with sheaths a quarter of their length. Male *flowers* spiked, copious, handsome, the crefts of their *anthers* purple. Female *flowers* oval, deep purple, their scales broad, the larger lip only very slightly pointed. *Cones* usually two or three together, sessile, spreading, scarcely half the length of the leaves, ovate, obtuse, their scales a little tumid, but quite destitute of spines or points. In close forests, Mr. Pursh says, this species grows very tall, with a remarkably smooth red bark. The timber is very heavy, and therefore unfit for masts.

12. *P. variabilis*. Two and three-leaved Pine-tree. Yellow Pine. Lamb. 22. t. 15. Willd. n. 12. Ait. n. 11. Pursh n. 11. (*P. mitis*; Michaux Arb. For. v. 1. 52. t. 3.)—Leaves two or three together, channelled with short sheaths. Cones oblong-ovate, nearly solitary, stalked, drooping; their scales with short inflexed spines. Found in moist pine forests, from New England to Georgia. *Pursh*. Mr. Lambert has seen but two trees of this kind in England, one at Pain's hill, the other at Kew; nor has he delineated the male flowers. This author speaks of the wood as too spongy and light to be durable; but Mr. Pursh says "the yellow pine is the most in use for building of houses as well as ship-

ping." The diversity of number among the *leaves* on the same branch is peculiar. Their length, almost two inches, rather exceeds that of the *cones*. Their *sheaths* are short.

13. *P. Teda*. Frankincense Pine-tree. Linn. Sp. Pl. 1419. Willd. n. 14. Ait. n. 13. Pursh n. 15.—Leaves three together, elongated, with long sheaths. Cones ovate-oblong, deflexed; their scales with inflexed spines. Crests of the anthers imbricated, orbicular.—Native of barren sandy situations, from Virginia to Florida. Mr. Pursh says this, which he terms the Loblolly, or Old-field Pine, "is found in large tracts in the southern states. All the woods seem to be feeded with it; for when any piece of cleared land is neglected, for any space of time, it will be covered with those pines. It is difficult, and in some cases almost impracticable, to recover those lands run over with young pines, as the ground appears to have lost all fertile properties for any other vegetable than those trees." The *leaves* are three from each sheath, larger, and their *sheaths* longer, than even in *P. resinosa*. Male *flowers* capitate, of a glowing yellow, the crefts of their *anthers* orbicular and crowded, or imbricated, over each other. The length of the *leaves* is about six inches; that of the *cones* about three. Their *spines* are very sharp, broad at the base, short, all inflexed. *Fig. c* of Mr. Lambert's t. 16, we have already cited as another species; see *pungens*, n. 3. His reference to Wangenheim, and the observations borrowed from that author, are also misplaced here, belonging rather to *rigida* or *serotina*, in Mr. Pursh's opinion. *P. Teda* flowers in America about April or May. It would be well worthy of cultivation in England, on barren sandy heaths, where nothing else of value will thrive; but though it has been known above a century in our gardens, nobody seems to have taken up this species as an object of ornament or economy.

14. *P. rigida*. Three-leaved Virginian Pine-tree. Common American black, or pitch, pine. Mill. Dict. ed. 8. n. 10. Lamb. 25. t. 18, 19. Willd. n. 13. Ait. n. 13. Pursh n. 12. Michaux Arb. For. v. 1. 89. t. 8.—Leaves three together, elongated, with shortish sheaths. Cones clustered, ovate; their scales with reflexed spines. Crest of the anthers rounded, jagged. Found in the plains, from New England to Virginia, either in dry, or wet low situations, blossoming in May. *Pursh*. It often grows to a large size. The numerous clustered *cones* afford a striking character at first sight. The *leaves* are about three or four inches long, rough at the points; their *sheaths* of a much shorter proportion than those of *P. Teda*. The spines of the *cones* being reflexed, not inflexed, will, at any time, distinguish them. The wood is not excellent.—*P. serotina*; Mich. Boreal-Amer. v. 2. 205. Mich. Arb. For. v. 1. 86. t. 7. Willd. n. 16. Pursh n. 13, of which a cone is given in Lambert's t. 19. f. 5; *P. Teda* δ ; Ait. H. Kew. ed. 1; the β of the 2d edition; appears, by Mr. Pursh's account, to be but a variety of the *rigida*, growing on the edges of ponds and swamps.

15. *P. palustris*. Swamp Pine-tree. Long-leaved, or Broom Pine. Mill. Dict. ed. 8. n. 14. Lamb. 27. t. 20. Willd. n. 15. Ait. n. 14. Pursh n. 16. Sm. Abb. Inf. v. 1. 83. t. 42. (*P. australis*; Mich. Arb. For. v. 1. 64. t. 6.)—Leaves three together, very long, drooping, with long sheaths. *Stipulas* pinnatifid, reflexed, permanent. Cones somewhat cylindrical, prickly.—Native of forests near the sea coast, from North Carolina to Florida. *Pursh*. Seldom seen in our gardens, except of a very small size, being tender. A tree at Kew, with its copious drooping *leaves*, 12 or 15 inches long, makes a beautiful appearance. The male *flowers*, which Mr. Lambert was obliged to have drawn from a dried American specimen, are capitate, very long.

PINUS.

long, with imbricated orbicular tawny crests to the *anthers*. *Cone* 10 or 12 inches long, each scale tipped with a small, prominent, rather incurved, spine. The points of the *leaves* are finely serrated; their *sheaths* long, splitting at the top into linear, recurved, jagged segments. *Stipulas* at the base of the sheaths, and not half so long, linear, recurved, acute, torn in a pinnatifid manner.

16. *P. longifolia*. Long-leaved Pine-tree. Lamb. 29. t. 21. Willd. n. 17. Ait. n. 15.—Leaves three together, very long and slender, drooping, finely serrated, with long sheaths. *Stipulas* entire, deciduous. *Cones* ovate, with prominent, angular, recurved, minutely-spinous scales.—Native of the lofty mountains of Nepaul, in the East Indies, where, according to Dr. Roxburgh, this tree grows to the height of 100 feet, blossoming about the beginning of the hot season. It is marked as a green-house plant in Hort. Kew. and said to have been introduced by Messrs. Gray and Wear, in 1801. Nothing can be more beautiful than the copious tuft of slender, pendulous, rough-edged *leaves*, near 18 inches long, as exhibited in Mr. Lambert's beautiful plate. The male *flowers* are rather capitate than spiked. *Cones* (of which a solitary perfect specimen is given in a second impression of that plate, instead of two which prove to belong to a different and undescribed species, see p. 91.) ovate, four inches long, distinguished by the unusually prominent recurved points of their *scales*. The head of this lofty tree is said to be round and small, affording little shade.

17. *P. Strobus*. Weymouth Pine-tree. Linn. Sp. Pl. 1419. Willd. n. 20. Ait. n. 16. Pursh n. 17. Lamb. 31. t. 22. (*P. americana*, *quinis ex uno folliculo fetis*, &c.; Hort. Angl. 57. t. 17. f. 1.)—Leaves five together. *Cones* cylindrical, imbricated, smooth, longer than the leaves. Crest of the *anthers* of two minute awl-shaped bristles. Found on the sides of hills, in a fertile soil, from Canada to Virginia, flowering in May. It is the largest and most useful of all the American Pines, and the best timber for masts, growing, in the state of Vermont, to an enormous size. *Pursh*. The attention which lord Weymouth, afterwards marquis of Bath, gave to the cultivation of this valuable tree, has justly stamped it with his name. It is now generally diffused through every considerable plantation. Its timber is excellent. The *leaves* are very slender, and differ from all the preceding in growing five from each sheath. In winter they approach the branch in an erect posture; in summer they spread widely. The male *flowers* are distinguished by the peculiar crest of their *anthers*. The long, taper, smooth, deflexed *cones*, with broad flat scales, are very peculiar, and, in a green unripe state, singularly elegant.

18. *P. Cembra*. Siberian Stone Pine-tree. Linn. Sp. Pl. 1419. Willd. n. 18. Ait. n. 17. Lamb. 34. t. 23, 24. Pall. Ross. v. 1. 3. t. 2. (*P. maritima altera*; Matth. Valgr. v. 1. 93. p. n° 30; Gmel. Sib. v. 1. 179. t. 39. P. n. 20; Duham. Arb. v. 2. 127. t. 32. *P. sylvestris*, *cembro*; Camer. Epit. 42.)—Leaves five together. *Cones* ovate, imbricated. Wing of the seeds obliterated. Crest of the *anther* kidney shaped, crenate. Native of the alps of Siberia, Tartary, Switzerland, Italy, &c. In Switzerland it is known by the name of *Aphernoussi*. Mr. Aiton records it to have been cultivated in 1746, by Archibald, duke of Argyle. Being of extremely slow growth, only very small plants of this species are usually seen in collections. The finest we have observed were at Mill Hill; but after the deplorable havoc made there by ignorant or negligent possessors, we know not whether these trees still exist. (See COLLINSON.) They were supposed

to be sixty or seventy years old in 1802, when we saw them in fine flower and fruit, being then but just arrived at the vigour of their growth, and by no means at full maturity. The aspect of the tree is not very handsome. The *leaves* are of a dull hue, fine and slender like the Weymouth pine, with which they agree in number. Male *flowers* copious, capitate; the *anthers* and their rounded crests tipped with purple. *Cones* ovate, thick, two inches or more in length, purplish, with a plum-like bloom; their scales thick, obtuse, with a somewhat corky surface. *Seeds*, which we have never seen perfected in England, almost destitute of a wing, obovate, resembling those of *P. Pinea*, like which they are eatable; but their shell is more easily broken.

19. *P. occidentalis*. West Indian Pine-tree. Swartz Ind. Occ. v. 2. 1230. Lamb. 36. Willd. n. 19. (*P. foliis quinis ab eodem exortu*; Plum. Ic. 154. t. 161.)—Leaves five together, rough-edged, very long. *Cones* ovate, tessellated, shorter than the leaves; their scales minutely spinous. Wing longer than the seed.—Native of the mountains of Hispaniola, according to Dr. Swartz, who never saw more than one tree of this species, and a nearly destroyed *cone*. He describes it as fifty feet or more in height, with upright uneven rugged *branches*. *Leaves* crowded about the extremities of the branches, five from each sheath, a span long, linear-awlshaped, triangular, with rough, or finely serrated, edges. *Cones* three inches long, deflexed. Plumier's figure agrees with this account, but it very distinctly shews the cone to be not, as Swartz subsequently says, imbricated, but tessellated like most of the first-described species, each scale having an abrupt angular termination; whereas in *P. Strobus* and *Cembra*, the only two species besides that have five leaves from one sheath, the scales of the *cones* are truly imbricated over each other. The *seeds* moreover being, as far as we can judge from Plumier's plate, considerably winged, differ widely from those of *Cembra*; as the whole *cone* does from that of *Strobus*, to which latter species Burmann, the editor of Plumier, most incautiously referred his plant.

SECT. 2. *Leaves solitary, scattered*. **ABIES** of Tournefort. Eleven species.

20. *P. Abies*. Norway Spruce Fir. Linn. Sp. Pl. 1421. Willd. n. 32. Ait. n. 18. Lamb. 37. t. 25. Fl. Dan. t. 193. Woodv. Med. Bot. t. 208. (*Picea*; Matth. Valgr. v. 1. 88. Camer. Epit. 47. *P. major*; Ger. Em. 1354.)—Leaves solitary, quadrangular. *Cones* cylindrical; their scales rhomboid, flattened, waved and notched. Common filament shorter than the bracteas.—Native of mountains in various parts of Europe, as well as the north of Asia, in places watered by alpine rills, where it grows to a lofty height, and makes a magnificent appearance. Though not a native of this island, few trees have been more generally or longer cultivated here; its stately though formal growth, and especially the fine colour of its evergreen leaves, rendering it very ornamental. The wood is also one of the most valuable sorts of deal, and the forests of Norway afford it abundantly. Mr. Lambert however informs us, that what is grown in England is most durable, and particularly esteemed for making ladders. Burgundy pitch is prepared from this species. The height of the tree is from 100 to 150 feet. It flowers in April. The long sweeping fan-like branches, often broken down by loads of snow, and the effect of boisterous winds, have a grand effect in alpine landscapes, and have been well employed in the sublime compositions of Salvator Rosa, and the German engravers. The *leaves* are copiously scattered all round the branches, ascending, somewhat imbricated, each scarcely

PINUS.

an inch long, on a short stalk, smooth, linear, curved, bluntish, with four rather unequal angles, and as many intermediate hollows. *Stipulas* none. *Flowers* terminal; the males most plentiful, of a tawny red; their *bracteas* numerous, spreading, longer than the common filament or basis of the *filaments*; anthers yellow, their crest crimson, roundish kidney-shaped, deeply and acutely jagged. Female *catkins* sessile, oblong, erect, of a rich crimson. *Cones* pendulous, solitary at the end of each branch, a span long, nearly cylindrical, light brown, smooth, of numerous, imbricated, flattish, rigid, rhomboid scales, waved at the edge, and notched at the point. *Seeds* small, with large elliptic-oblong wings.

21. *P. alba*. White Spruce Fir. Ait. H. Kew. ed. 1. v. 3. 371. Lamb. 39. t. 26. Willd. n. 34. Ait. n. 19. Pursh n. 7. (*Abies alba*; Mich. Arb. For. v. 1. 133. t. 12. *A. piceæ* foliis brevioribus, conis parvis biuncialibus laxis; Hort. Angl. 2. t. 1. f. 3.)—Leaves solitary, quadrangular, incurved. *Cones* nearly cylindrical; their scales obovate, wavy, entire. Common filament drooping, twice as long as the bracteas.—Native of high mountainous tracts in the colder parts of North America, flowering in May. Cultivated in England by bishop Compton before 1700. *Miller*. It vies with the last in general form, but not in loftiness, but the leaves are rather smaller, more swelling upwards, and more incurved, with a glaucous hue, and the bark of the trunk is whiter. The flowers are all smaller; the males distinguished by the great length of their common filament, which is quite pendulous. The cones are not above two inches long, their scales obovate, not rhomboid. Mr. Lambert strongly recommends the planting of this tree, on a large scale, on mountainous barren heaths in England and Ireland. Mr. Pursh however says its wood is not so good as that of the following, nor the tree so lofty; neither are its branches fit for making spruce beer.

22. *P. nigra*. Black Spruce Fir. Ait. Hort. Kew. ed. 1. v. 3. 370. Lamb. 41. t. 27. Willd. n. 31. Ait. n. 20. Pursh n. 5. (*Abies nigra*; Mich. Arb. For. v. 1. 123. t. 11. *A. piceæ* foliis brevioribus glaucis, conis biuncialibus laxis; Mill. Ic. t. 1.)—Leaves solitary, quadrangular, straight. *Cones* ovate; their scales elliptical, notched at the end. Common filament erect, the length of the bracteas.—Native of the tracts of high mountains, from the more northern parts of Canada to Carolina, flowering in May. *Pursh*. It was introduced into England at the same time as the last, but is not much cultivated here. The wood is said by Mr. Pursh to be better than the White Spruce, and the young branches are used for making the well-known spruce beer. The leaves and flowers are somewhat smaller than the last; the males erect, orange-coloured, their common filament no longer than the erect bracteas, the crest of their anthers rounded, finely fringed. The cones are ovate, hardly above an inch long, crowded about the sides of the last-year's shoots, which have protruded beyond them, and before they become dry, are of a rich deep purple.

23. *P. rubra*. Red Spruce Fir. Lamb. 43. t. 28. Willd. n. 33. Ait. n. 21. Pursh n. 6.—Leaves solitary, awl-shaped. *Cones* oblong, obtuse; their scales rounded, somewhat cloven, the margin entire. Common filament shorter than the bracteas.—Found in Nova Scotia, and about Hudson's Bay, flowering in May. Though *Miller* appears to have known this tree in cultivation, it is at present rarely seen, nor does it excite attention, except from the more curious observers. It is of more humble growth than the *nigra*, which it most resembles, except that the leaves are awl-shaped; the unripe cones of a pale purplish-green, and

when ripe rather oblong than ovate, their scales rounded, and not notched, but split. The shoots are said to make spruce beer.

24. *P. orientalis*. Oriental Fir. Linn. Sp. Pl. 1421. Willd. n. 35. Lamb. 45. t. 29. (*Abies orientalis*, folio brevi et tetragono, fructu minimo deorsum inflexo; Tourn. Cor. 41. Voy. v. 2. 104. letter 17.)—Leaves solitary, quadrangular. *Cones* ovato-cylindrical, pendulous; their scales somewhat rhomboid.—Gathered by Tournefort, on lofty mountains above the convent of St. John, 25 miles south-east of Trebifonde. The modern Greeks know this tree by the name of ελάτη, and it seems to be the only species of the spruce tribe that Tournefort found in the Levant. We know it merely from Mr. Lambert's plate, in which a copy of Aubriet's sketch of an original specimen, bearing two cones, is given; along with a coloured representation of two other cones, from China, judged by Mr. Lambert to belong to the same species. The leaves of Tournefort's plant are very short, being hardly half an inch long, somewhat incurved. *Cones* two inches long, stalked, quite pendulous, ovate and tapering, with rounded, entire, even scales; those of the Chinese plant are more sessile, with more rhomboid wavy scales.

25. *P. picea*. Silver Fir. Linn. Sp. Pl. 1420. Willd. n. 26. Ait. n. 22. Lamb. 46. t. 30. Woodv. Med. Bot. t. 209. (*Abies mas*; Ger. Em. 1363, 1364.)—Leaves solitary, flat, somewhat two-ranked. *Cones* cylindrical, erect, with long-pointed scales. Crest of the anthers with two horns.—Native of the mountains of Siberia, Germany, and Switzerland; but not of Scotland, as Linnæus and Willdenow state; nor of Sweden, as the latter erroneously borrows from the former, printing *Suecia* for *Suevia*. A tall and handsome tree, cultivated for ornament in England, and flowering in May. Its bark is smooth and whitish. *Branches* horizontal. *Leaves* copious, linear, either acute or emarginate, entire, spreading, more or less perfectly, in two ranks, and sometimes curved toward one side; their upper surface of a dark, shining, rather glaucous, green; the under glaucous-white. Male flowers numerous, axillary, solitary, about as long as the leaves, yellow; their common filament the length of the toothed bracteas; anthers remarkable for their rounded two-lobed crest, crowned with a pair of divaricated horns. Female catkins lateral, erect, cylindrical, green, one lip of each scale, much the narrowest, distinguished by a long, projecting, awl-shaped point, very conspicuous in the full-grown cones, which are also erect, three or four inches long, cylindrical, of a reddish-green, till they turn brown in drying. *Gmelin* asserts that forests of this tree are considered, by the wandering Tartars, as a sure indication of good springs, as it delights in moist rich situations; an obstacle to its being planted much for profit in England.

26. *P. Balsamea*. Balm of Gilead Fir. Linn. Sp. Pl. 1421. Willd. n. 27. Ait. n. 319. Pursh n. 1. Lamb. 48. t. 31. (*Abies balsamifera*; Mich. Boreal-Amer. v. 2. 207. Mich. Arb. For. v. 1. 145. t. 14.)—Leaves solitary, flat, imperfectly two-ranked. *Cones* cylindrical, erect, with short-pointed scales. Crest of the anthers pointless.—Native of Canada, Nova Scotia, New England, and the Alleghany mountains, in high cold situations, flowering in May. *Pursh*. It has long been cultivated for curiosity in England, but in general, though it grows to a considerable size and height, scarcely survives above 20 years, which seems to be the natural period of its existence. In this respect our observations agree with those of *Miller* and Mr. Lambert; though the latter has been told of some older trees of this species at Wooburn and Warwick-castle. Its fragrant ex-

PINUS.

udation is the well-known Canada balsam, which some quacks celebrate as Balm of Gilead, to their own profit, if not to that of their patients. Combined with some kind of spirits, it makes a not unpleasent dram. This tree and its foliage are not much unlike the last, but the above characters clearly distinguish it. The full-grown *cones* are of a beautiful violet hue, and exude plenty of candied turpentine or balsam, as does the trunk when wounded.

27. *P. Frazeri*. Double-balsam Fir. Pursh n. 2.—Leaves solitary, flat, emarginate. Cones ovate-oblong, erect, their scales elongated, reflexed, oblong-wedged-shaped, emarginate, short-pointed, toothed. Found on the high mountains of Carolina, by the late Mr. Frazer, by whom it has been introduced into England. Mr. Pursh, who met with the same species on the Broad-mountains, Pennsylvania, describes it as a smaller tree than the last, with shorter more erect *leaves*, and *cones* not one-fourth so large.

28. *P. taxifolia*. Nootka Fir. Lamb. 51. t. 33. Willd. n. 29. Pursh n. 3.—Leaves solitary, flat, entire. Cones oblong. Anthers of two inflated lobes; their crest minute, reflexed; common filament shorter than the concave fringed bractæas.—Gathered by Mr. Menzies at Nootka found; “by Mr. Lewis on the banks of the Columbia.” *Pursh*. A tall elegant tree, bearing some resemblance to the following, but the *leaves* are more than twice as long, and entire. The *anthers* too, as far as they could be made out from a dried specimen, appear very different; and the *cones* are said by Mr. Menzies to be longer, as well as differently shaped.

29. *P. canadensis*. Hemlock Spruce Fir. Linn. Sp. Pl. 1421. Willd. n. 30. Ait. n. 24. Pursh n. 4. Lamb. 50. t. 32. (*Abies canadensis*; Mich. Boreal-Amer. v. 2. 206. Mich. Arb. For. v. 1. 137. t. 13.)—Leaves solitary, flat, two-ranked, finely toothed. Cones terminal, ovate, scarcely longer than the leaves. Anthers capitate, beaked; common filament twice as long as the bractæas.—“Native of the most northern regions of Canada, and on the highest mountains, as far as South Carolina, flowering in May. A very elegant tree, growing in some situations to an enormous size; its bark is a fine substitute for oak-bark in tanning.” *Pursh*. Peter Collinson records his having introduced this tree, in 1736, to the English collections, and a fine specimen of it is, or was, in his garden at Mill Hill. The aspect of the Hemlock Spruce is rather gloomy, partaking more of the yew than of the fir. The male *flowers* are small, consisting of very few *anthers*, in a round head on a long common filament. The *cones* are scarcely an inch long, smooth, pale, of but few scales, and hang solitary at the ends of the small ultimate branches. The *leaves* are glaucous underneath in this, as well as in four species immediately preceding.

30. *P. lanceolata*. Lance-leaved Chinese Pine-tree. Lamb. 52. t. 34. Willd. n. 28. Ait. n. 25.—Leaves solitary, lanceolate, flat, spreading, with taper pungent points. Cones globose, with pointed scales.—Gathered by the late sir G. L. Staunton, bart. in the province of Chekiang, China, from whose specimen Mr. Lambert at first published an uncoloured figure. A coloured drawing, with a dissection of the *cone*, displaying the *seeds*, each of which is represented as encompassed with an oval wing, was subsequently sent from Canton by an artist in the employment of the East India Company; by all which Mr. Lambert has profited. Living plants have also been brought to Kew in 1804, and are now cultivated in the green-houses of that and some other choice collections, but have not yet blossomed. The aspect of this *tree* or *shrub*, for we know nothing of its natural stature, is so unlike all

other pines or firs, that its unripe *cones* were actually supposed to be excrescences, or galls, owing to the attacks of insects. The copious, deflexed, rigid, pungent *leaves*, near an inch and a half long, of a fine green, spread in every direction; they are entire, but rough-edged, and furnished with three ribs. *Cones* about as big as wall-nuts, sessile, rather drooping, almost globular, of many ovate pointed scales.

SECT. 3. *Leaves numerously tufted from each sheath.* LARIX of Tournefort. Four species.

31. *P. Larix*. Common, or White, Larch-tree. Linn. Sp. Pl. 1420. Willd. n. 24. Ait. n. 26. Lamb. 53. t. 35. Woodv. Med. Bot. t. 210. (*Larix*; Matth. Valgr. v. 1. 95. Ger. Em. 1365. Camer. Epit. 45, 46.)—Leaves tufted, deciduous. Cones ovate-oblong; the margins of their scales reflexed, jagged. Scales of the female catkin fiddle-shaped, prominent in the full-grown cone. Native of the alps of Switzerland, Italy, Germany, Siberia, &c., long cultivated very extensively, and with great advantage in this country, flowering in March and April, before the leaves fully expand, in which state it makes an elegant appearance. Mr. Lambert's plates of this and the following are no less beautiful pictures, than exquisitely faithful botanical drawings. The same may indeed be said of his whole work. The larch is a tree of straight and lofty growth, as well as large bulk, with wide-spreading *branches*, whose extremities droop in the most graceful manner. In a wild state its form is, of course, less regular, but more picturesque. The *buds* are alternate, perennial, cup-shaped, scaly, each producing annually a pencil-like tuft of very numerous, spreading, linear, bluntish, entire, smooth, tender, bright-green, deciduous *leaves*, about an inch long, with no other *stipulas* than the scales of the bud. How many years each bud endures, we have not determined, but certainly above four or five. From similar buds spring separately, on the same branch, the male and female *flowers*, the latter only accompanied by a few leaves; but it seems to us, that the male buds become entirely leaf-buds, in the succeeding seasons. *Bractæas* to each flower numerous, recurved, obtuse, with fine fringe-like teeth, chaffy, red-brown, deciduous. Male *flowers* yellow, drooping, about half an inch long. Common *filament* much shorter than the *bractæas*; *anthers* crowded, deflexed, inflated, and two-lobed in front, with a short recurved point. Female *catkins* erect, larger than the male *flowers*, beautifully variegated with green and pink; one lip of each scale orbicular; the other much larger, fiddle-shaped, reflexed, with a prominent, awl-shaped, green point. This lip becomes erect, and somewhat enlarged, projecting always beyond the orbicular one, which dilates greatly, hardens, and becomes the seed-bearing scale of the *cone*. The *cones* are erect, rather above an inch long, ovate; purple when young; reddish-brown when ripe, light, not ponderous, their scales spreading, orbicular, slightly reflexed, and jagged, or cracked, at the margin. Wing of each *seed* half-ovate.

32. *P. pendula*. Black Larch-tree. Tamarack or Hackmatack of the Americans. Ait. Hort. Kew. ed. 1. v. 3. 369. Lamb. 56. t. 36. Willd. n. 22. Ait. n. 27. Pursh n. 18.—Leaves tufted, deciduous. Cones oblong; the margins of their scales inflexed. Scales of the female catkin fiddle-shaped, concealed in the full-grown cone.—Found in low cedar swamps, from Canada to New Jersey, flowering in April and May. *Pursh*. It was first raised in England by the celebrated P. Collinson, whose original tree, one of the treasures of the Mill Hill garden, was cut down about the year 1800, to make a rail, by its sapient possessor. The abundance of seeds, which it annually produced, might

have

PINUS.

have been a far more lasting source of profit, as few exotic trees are more worthy of general cultivation. The wood is at least equal to the European larch, and the bark excellent for tanning. The habit and foliage resemble the preceding, but the female *catkins* are represented by Mr. Lambert of a more crimson hue. The fiddle-shaped pointed lip of each of their scales is four or five times as big as the orbicular one, but never increases after the flowering period; so that it becomes entirely concealed, in the full-grown *cones*, by the enlarged orbicular lips, that constitute the proper scales of the *cones*, and twice exceed it in length. This circumstance did not escape the excellent Solander, who first described the present species, from Mr. Collinson's garden. The *fructification* for the most part agrees with *P. Larix*, inasmuch that it is difficult to find specific distinctions. The *cones* however are smaller, more cylindrical, with rather fewer scales, whose edges are slightly inflexed, and this, added to the want of the pointed prominences seen in the foregoing, give the full-grown dark purple *cones* a peculiar neatness and smoothness of appearance.

33. *P. microcarpa*. Red Larch-tree. Lamb. 58. t. 37. Willd. n. 23. Ait. n. 28. Pursh n. 19. (*P. pendula*; Willd. Baumz. 215. *Larix americana*; Mich. Boreal. Amer. v. 2. 203. Mich. Arb. For. v. 3. 37. t. 4.)—Leaves tufted, deciduous. Cones roundish, of few scales; their margins inflexed. Scales of the female catkin oval, concealed in the full-grown cone.—Found about Hudson's Bay, and on high mountains of New York and Pennsylvania, flowering in May. Pursh. Michaux, it seems, has confounded this with the last, as did Willdenow in his valuable German work on hardy trees and shrubs, published at Berlin in 1796. This is similar to *P. pendula* in general appearance, but the leaves are rather smaller, and the cones considerably so, being rounder and composed of much fewer scales. The male flowers are more short and tufted, their anthers scarcely projecting beyond the bractæas. The pointed lip of each scale of the female catkin affords the most clear distinction, being elliptical, not fiddle-shaped. The copious crimson cones, fully grown but not ripe, make a beautiful appearance in summer. Such was the state of the tree of this species, which Mr. Lambert, in company with the writer of the present article, found unprotected in the middle of a pasture at Whitton, near Hounslow, where it had been planted by John duke of Argyle. It had however escaped injury, and was immediately secured from further danger. Both these American Larches are now in cultivation amongst the nurserymen, and deserve the attention of planters.

34. *P. Cedrus*. Cedar of Lebanon. Linn. Sp. Pl. 1420. Willd. n. 21. Ait. n. 29. Lamb. 59. t. 37. bis. (*Larix orientalis*, fructu rotundiore obtuso; Tourn. Inst. 586. Duham. Arb. v. 1. 332. t. 132. *Cedrus*; Trew Ehret. 1, 28. t. 1, 60, 61. Camer. Epit. 57. C. Libani; Ger. Em. 1352. Matth. Valgr. v. 1. 114.)—Leaves tufted, perennial. Cones ovate, abrupt; their scales close-pressed. Crest of the anthers ovate, flat, erect.—Native of mountains in the Levant, especially of the famous Lebanon, from whence seeds were obtained, and plants raised in the English gardens, towards the latter part of the seventeenth century. Two of the oldest of these venerable guests remain at Chelsea, and others of somewhat younger growth at Chiswick, Whitton, Pain's hill, &c. A very large one at Hillingdon was blown down above twenty years ago. The wide-spreading fan-like branches, and perennial leaves of this species, differ widely from the three foregoing. Its male flowers are extremely different, both in their long cylindrical form, and the erect ovate red crest of their anthers,

more agreeing with some of our first-described kinds. The female catkins are ovate, dull-purple; both lips of their scales nearly orbicular, and close-pressed. The larger has at its base, on each side, attached to the rudiments of the seeds, a pair of combined awl-shaped processes, that might be taken for styles or stigmas, could any analogous parts be found in other species of *Pinus*. These are, for the first time we believe, represented in a fine plate by Mr. Sowerby, added to Mr. Lambert's work after its original publication. Which of these lips changes into each hardened dilated abrupt scale, of the large ponderous cones, we have not had an opportunity of observing. Something similar to the above style-like processes of the Cedar, is shewn in Mr. Lambert's plate of *P. pendula*, at the dissected scales of the full-ripe cones; where however it has all the appearance either of pubescence, or of lacerated fibres.

SECT. 4. *Leaves opposite*. AGATHIS. Salis. Tr. of Linn. Soc. v. 8. 311. t. 15. One species.

35. *P. Dammara*. Amboina Pitch Pine-tree. Lamb. 61. t. 38. Willd. n. 25. Ait. n. 30. (*Dammara alba*; Rumph. Amb. v. 2. 174. t. 57.)—Leaves opposite, elliptic-lanceolate, striated.—Native of Amboina, where a fine inflammable resin exudes from the trunk when wounded, and is collected for some purpose, not clearly explained by authors. A kind of pitch is also said to be made from this tree, much used in the East Indies. Of its botanical history we know little. The elliptic-lanceolate, thick, rigid, opposite leaves, near three inches long and one broad, are widely different from every known *Pinus*, and there is every reason to suppose the *Dammara* constitutes a distinct and dioecious genus; though all that has as yet been explained relative to its fructification is little more than conjecture. The ripe cones are globular, close, hard, and woody, as big as a small orange, with tumid, tessellated, unarmed scales. Other cones bear something like anthers at the base of each scale. Living plants of *P. Dammara* were procured by Sir J. Banks for Kew garden in 1804, and are kept in the stove.

PINUS, in *Gardening*, contains plants of the evergreen and deciduous tree kinds, of which the species cultivated are; the wild pine-tree (*P. sylvestris*); the pinaster, or cluster pine-tree (*P. pinaster*); the Jersey pine-tree (*P. inops*); the American pitch pine-tree (*P. resinosa*); the Aleppo pine-tree (*P. halepensis*); the stone pine-tree (*P. pinea*); the torch pine-tree, or three-leaved Virginia pine (*P. tæda*); the swamp pine-tree (*P. palustris*); the Siberian stone pine-tree (*P. cembra*); and the West Indian pine-tree (*P. occidentalis*); the Weymouth pine-tree (*P. strobus*); the cedar of Lebanon (*P. cedrus*); the black larch-tree (*P. pendula*); the common white larch-tree (*P. larix*); the silver fir-tree (*P. picea*); the balm of Gilead fir-tree (*P. balsamea*); the hemlock spruce fir-tree (*P. canadensis*); the black spruce fir-tree (*P. nigra*); the Norway spruce fir-tree (*P. abies*); the white spruce fir-tree (*P. alba*); and the oriental fir-tree (*P. orientalis*).

The trunks of the first sort of these afford masts to our navy, and from them and the branches tar and pitch are obtained, as also by incision, barras, Burgundy pitch, and turpentine.

There are several varieties; as the Tartarian, which has a great resemblance to it, but the leaves are broader, shorter, and their points are more obtuse; they emit a strong balsamic odour when bruised; the cones are very small, as are also the seeds, some of which are black, and others white.

The mountain, or mughoe, which has very narrow green leaves, grows sometimes by pairs, sometimes by threes from the same sheath, generally standing erect; the cones are of a middling size, and pyramidal; the scales flat, having each

PINUS.

a small obtuse rising, but very compact till they are opened by the warmth of the sun the second spring; the seeds of this are much less than those of the second sort, but larger than those of the first. It is a native of the Swiss mountains, where it is often called torch pine, growing to a great height.

The sea pine, which has smooth leaves; the cones are very long and slender; and the seeds are about the same size with those of the second species. It grows in the maritime parts of Italy, &c.

Other varieties are likewise mentioned by writers.

Of the seventh sort there are different varieties; as the three-leaved Virginia, which has the leaves long, generally three in each sheath; the cones in clusters round the branches, as long as those of the second sort, but with rigid scales; the seeds also nearly as large as those of it. It grows naturally in Virginia, and other parts of North America, where it rises to a great height.

The other varieties differ but little from this.

The twelfth sort, or cedar, is now so far naturalized to our country as to produce ripe seeds; we may, therefore, have supplies without depending on the cones from the Levant: but it is found that they are more apt to produce and ripen their cones in hard winters than in mild ones; which is a plain indication that they will succeed even in the coldest seasons of the northern parts of the island, where, as well as in the other parts, they might be propagated to great advantage.

There are different varieties of the fourteenth sort; the American, the Siberian, and the Chinese, require a colder climate than England, for the trees are apt to die in the summer here, especially if they are planted on a dry soil; the cones of those which have been brought to England seem to be in general larger than those of the common sort; but there is so little difference between the trees in their characteristic marks, that they cannot be distinguished as different species, though in the growth of the trees there is a remarkable difference. In the last, the cones are much larger than those of the common sort, and end in acute points; the scales prominent, like those of the first species, and have little resemblance to those of the larch. They are of a shrubby, spreading growth, but so hardy as to thrive in the open air without any protection. But in the first, of which the branches are more slender, with a bark more inclining to yellow, and the scars more slender and clustered; the leaves are more tender, narrow, more glaucous, and the outer ones in each bundle shorter; cones only one-third of the size, blunt, with scales scarcely exceeding twelve in number, thinner, more shining, retuse, emarginate; the wings of the seeds are straight, more oblong, narrower, and, together with the seed itself, of a more diluted grey colour. And in the second, the bark of the branches is of an ash-coloured grey; the leaves a little wider, bright green, all nearly equal, commonly more than forty in a bundle; the cones an inch long, with above thirty woody, striated, rounded, entire scales; the seeds brownish-grey, with subtriangular wings, somewhat bent in. In both the cones are bent upwards, on very short peduncles.

It is observed by the editor of Miller's Dictionary, that "no tree is more valuable; or better deserves our attention in planting than the larch." It is a native of the south of Europe, and Siberia.

The timber is not only used in houses but in naval architecture also. "It seems to excel," he says, "for beams, doors, windows, and masts of ships; it resists the worm; being driven into the ground it is almost petrified, and will support an incredible weight; it bears polishing excellently

well, and the turners abroad much desire it. It makes everlasting spouts, pent-houses, and feather-edge, which need neither pitch nor painting to preserve them; excellent pails, posts, rails, props for vines, &c.; to these we may add the palettes on which painters separate and blend their colours."

It has been observed in Ireland, that no tree grows so speedily to so large a size as the fifteenth sort, or the silver fir. Some at forty years growth, in a wet clay on a rock, measuring twelve feet in circumference at the ground, and seven feet and a half at five feet high; one tree containing seventy-six feet of solid timber. The earl of Fife also remarks that no trees make a greater progress than this and the larch. It is found to be excellent for boat-building.

The seventeenth sort has very much the habit of the silver fir, but the leaves are wider and blunter, disposed on each side along the branches like the teeth of a comb, but in a double row, the upper one shorter than the under; underneath marked with a double glaucous line, and each has eight rows of white dots, and are often cloven at top.

The appellations of white and black in the seventeenth and eighteenth sorts are given from the colour of the bark, as there is little difference in the colour of the wood, and the leaves of the black are whiter on their under side than those of the white. They are both natives of North America; the white upon the mountains; the black upon the low grounds, generally in bogs or swamps. The first is by much the largest tree. This (the black) sort is easily known by its narrow leaves, placed on every side of the branches, and its long pendulous cones, which do not fall to pieces on the tree, but drop off entire the following summer; the scales open and emit the seeds on the first warmth of the spring.

There is a variety of this tree cultivated under the title of the long-coned Cornish fir, in which the leaves are longer, broader, of a lighter colour, and fuller on the branches; the cones also longer.

In the nineteenth sort there are two principal varieties; the white and the red, both of which afford the white deals. And *Burgundy pitch* is prepared from the resin procured from this tree by boiling and straining it through a cloth.

There is no tree that yields greater profit than the spruce fir in cold land; no tree is more beautiful standing single on turf in large plantations, or more useful for shelter in cold soils and situations.

Method of Culture.—In all the sorts and varieties the increase is effected by means of seeds, which may be obtained from the well ripened cones by exposing them to the heat of a gentle fire, or that of the sun, in which way the cells open and the seeds may be readily taken out. When the cones are not made use of in this way, they will remain several years without the seeds being injured, especially where they are close.

They should be sown in the early spring months, as March or the following month, on beds of fine earth, in a north-east aspect, or in large pots or boxes for the purpose of being occasionally removed into different situations as may be found necessary. They should be covered with nets to prevent the birds from pecking off the tops of the young plants, while the husks of the seeds are upon them; and be likewise screened from the heat of the sun at first.

All the sorts, except the stone pine and a few others, the scales of the cones of which are very hard, soon come up; but these frequently remain more than a year; the ground should therefore not be disturbed, being only kept clean from weeds in such cases.

Soaking

Soaking the seeds in these cafes may be useful, as well as sowing them in shaded situations.

The young plants in all the forts should be kept quite clean, and occasionally refreshed with water when the season is dry, in a very gentle manner, so as not to disturb the plants.

When they come up too close, the plants should be thinned out in the summer, the thinnings being planted out immediately in a separate bed, in a shady place, being gently watered as there may be occasion. They should be set out in rows at the distance of four or five inches, and three or four in the rows. The tender kinds should be sheltered during the winter by frames or mats from the frosts, but with the others it is unnecessary.

When the plants have remained in these beds a year or more according to circumstances, they should be removed into other rows in the nursery at the distance of two feet, and one or more in the rows. In this situation they should remain till the periods of their being finally planted out.

The best season for the removal of the plants in all cafes is towards the latter end of March, or the beginning of the following month.

Where it can be done, it is the best way not to let them remain too long in these nursery situations, as the plants are always found to succeed best when planted out before they have acquired too large a growth.

When large plantations are to be made, it is advised by some to raise the plants on a portion of the same ground, or as nearly similar to it as possible.

It is advantageous when they are to remain, to have a large size to transplant them every two years, as by that means they form better roots, and such as spread out more laterally, and of course the plants may be afterwards removed with greater safety.

In removing the plants, at all times great care should be taken to preserve the roots as much as possible, as well as all the branches, without cutting them.

When they have been finally removed, they require little more trouble, it being only necessary to keep them perfectly free from weeds, and supporting the larger forts of plants with proper stakes; all the forts should be suffered to take their own natural growth; being careful to preserve their tops perfectly entire, to shoot up as fast as possible, and to branch out in their own way, as no pruning is wanted, unless in the lowermost branches in particular trees which are thought too low and straggling, when these may be occasionally trimmed, cutting them close to the stem; but pruning should be very sparingly practised to these resinous trees, as lopping the branches contributes to retard their growth as well as impair their beauty. In large forest plantations, where the trees are arrived to a large growth, it is, however, customary to lop their lower branches gradually for faggots, according as they begin to decay; for where these trees stand close, the upper branches generally kill those below, so that the lower tiers decay gradually and successively; in which case these decaying lower branches may be lopped by degrees in winter.

After the plantations designed for timber-trees have had eight, ten, or twelve years' growth, it may be proper to begin to thin them; those thinned out may serve for many smaller purposes, being careful in thinning to leave a sufficiency of the finest plants standing at proper distances to grow up for timber.

These trees are all highly ornamental evergreens for the pleasure-grounds.

In regard to the distribution or arrangement of the trees in the plantations, and mode of planting, those designed for

the shrubbery and for ornamental plantations may be disposed both in assemblage with other trees, and to form clumps, and continued plantations. Those intended as forest trees should generally be disposed alone in considerable plantations. The method of planting them is the same as in other hardy trees; but where large plantations in out-grounds are intended either for pleasure or profit, there will not be any great necessity for a previous preparation of the soil, with respect to digging or ploughing, only just to dig a hole for each tree; the same rule may also be observed in planting clumps of them in lawns, parks, and other grass-grounds, the mould being made fine in the bottoms of them. Those designed principally for ornament should be disposed at such distances as that their branches may extend freely every way; as the beautiful display of the head is a great merit in these trees in such plantations; but those intended for timber plantations may be put only four or five feet distant, in order that they may draw one another up straight and tall more expeditiously, and to admit of a gradual thinning after a few years' growth, for poles, &c.

The proper methods of raising and planting out all the different forts, in the view of affording timber or shelter in large plantations, may be seen in the new edition of Miller's Dictionary.

PINUS, in *Ornithology*, a species of *Certhia*; which see.

PIN-YANG, in *Geography*, a city of China of the first rank, in Chan-si; 337 miles S.W. of Peking. N. lat. 36° 6'. E. long. 111° 0'.

PIO, ALBERTO, in *Biography*, prince Carpi, son of Leonello, lord of Carpi, by a sister of the celebrated Giovanni Pico of Mirandola, was born about the year 1475, and first studied in the university of Ferrara under Pomponazzo. He pursued his studies with great ardour at Carpi, whither he had invited several learned men, among whom he distinguished Aldo Manuzio as his particular instructor. After his father's death, he, with his brother Leonello, had a common dominion in the territories of Carpi, with Giberto and other sons of Marco, another branch of the same family. This divided authority produced dissensions, which, from 1494 to 1500, occasioned a bloody civil war. After a time, Alberto connected himself with the French party, and in 1510 he visited the court of Lewis XII., and was dispatched by him in a mission to pope Julius II., and some circumstances now occurred which led him to believe that it was his interest to quit the French party, and to join that of the Imperial, the latter being the stronger in Italy, which he did not hesitate to say was the motive by which he was governed in his political alliances. He resided a long time at Rome as the emperor's ambassador at the papal court, and was singularly esteemed by Leo X., who conferred upon him several castles in Romagna. In the subsequent wars his principality was frequently taken by different parties, and Alberto was possessed and dispossessed of the sovereignty. He again adopted the French interest, which occasioned the final loss of Carpi, that was transferred by Charles V. to Alfonso, duke of Ferrara. He was at Rome during its sack in that year; and took refuge with Clement VII. in the castle of St. Angelo. Being afterwards delegated by the pontiff to Francis king of France, he was very handsomely received by that monarch, and died at his court in 1531, in the 56th year of his age. Notwithstanding the vicissitudes of his life, and his various political occupations, Alberto did not cease the cultivation of letters; he was a zealous adherent to the see of Rome, and gave all the opposition in his power to the doctrines of the reformers. At this time Erasmus made a considerable figure in the world, and Alberto spoke pretty freely of the tendency of his various

rious publications, and what he said was reported with much aggravation to that celebrated man. In consequence he wrote, in October 1525, a letter to Alberto, acquainting him in a friendly manner with what he had heard, and joining a short defence of himself. To this Alberto replied in a long epistle, which, with Erasmus's letter, was afterwards published at Paris. This led to farther discussion on both sides, and in one of his letters, Alberto launched out into an examination of all the works and opinions of Erasmus, and of those of Luther, and the other innovators of the time. He died, while the work was printing, at Paris, but it appeared in the same year under the title of "Alberti Pii, &c. tres et viginti libri in locos lucubrationum variorum D. Erasmi Rotter." This work is highly commended by Tiraboschi, who says "it has none of the scholastic barbarism, but is written with erudition, force, and not without elegance." It should be observed, that he was supposed to have been assisted by Sepulveda, and other learned men whom he kept in his house. His works have been collected and published in folio at Paris, and also at Venice.

PIOBBICO, in *Geography*, a town of the duchy of Urbino; 11 miles S. of Urbino.

PIOBRACH, a Gaelic term, denoting an air played upon the bag-pipe; and now more strictly applied to the ancient Highland martial music. This air is said to be peculiarly expressive. Piobrachs are either simple or compound; some of them consist of a march, &c. and are beautifully varied, and highly characteristic.

PIOMBA, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 42° 56'. E. long. 13° 9'.

PIOMBINO, a principality in the central part of Italy, consisting of a small portion of the Italian shore, and the opposite isle of Elba, subject, in the 13th century, to the Pisans, and after several revolutions transferred to the family of Appiano, as a detached principality, in 1399. In 1501 it was seized by César Borgia, but after the death of pope Alexander VI. returned to the house of Appiano. In the 16th century the isle of Elba was repeatedly ravaged by the Turks. The principality recently passed to the house of Buoncompagni, that is, the dukes of Sora, a Neapolitan family, which owes its fortune to the pontiff Gregory XII., and in 1801 annexed to the new kingdom of Etruria. It is situated on a peninsula, in a bay of the Mediterranean, called "the gulf of Piombino." Piombino is a small neglected town; 33 miles S.W. of Sienna. N. lat. 42° 57'. E. long. 10° 34'.

PIOMBO, SEBASTIAN DEL, in *Biography*, called also *Venetiano*, from Venice, the place of his birth, which occurred in 1485. He was renowned in early life as a musician, and particularly for his skill in playing upon the lute. While he was yet in his youth, he abandoned that science, and was taught the rudiments of the art of painting by Giovanni Bellini; but as Giorgione da Castel Franco had just then exhibited his improved mode of colouring and effect, Sebastian placed himself under his tuition; and in the end acquired a well merited and great renown, both in painting portraits and historical subjects.

His first essays were in the former class, and they were greatly admired for the strength of resemblance, and the sweetness and fulness of style with which they were executed; and were frequently mistaken for the work of Giorgione. His portrait of Giulio Gonzaga, the favourite of cardinal Hippolito di Medici, is by many writers spoken of with extreme delight, and called a divine performance, full of life and character. He finished his works with great care; folding his draperies with great felicity, and giving great truth and exactness of action to the heads and hands.

By the persuasion of Agostino Ghizi, a rich merchant of Sienna, he was induced to go to Rome; where the novelty of his style, and his skill in execution, soon drew him into public notice. He there became an historical painter, and wrought equally well in fresco and in oil. In the contest of opinion which took place at that time concerning the superiority in merit of Raphael, or M. Angelo, Sebastian gave the preference to the latter, and gained his esteem and support. In consequence he was favoured by him on all occasions; and so highly estimated, that he stimulated him to the rash attempt of rivalling Raphael; particularly by painting a picture in competition with that great man's last great work, the Transfiguration; which had just been placed, with great éclat, in the church of St. Pietro à Montorio. The subject Sebastian chose, was the resurrection of Lazarus; for which Michael Angelo is supposed to have furnished the design, or at least to have considered and retouched it. The picture is of the same size as Raphael's, and, when completed, was placed in the same Confraternity, and was very highly applauded. The cardinal di Medici sent it to his bishopric of Narbonne, and it became the property of the duke of Orleans. It is now in England, and in possession of J. Angerstein, Esq. who gave 2000 guineas for it to the proprietors of the Orleans collection. Although it is a work of profound skill, and highly preserves the reputation of its author, yet, in our opinion, it is not to be compared with the great work it was intended to rival, either in design, in expression, or effect; whatever may be said of its execution.

Sebastian continued to exercise his talents, particularly in portraiture, with great industry and success, till he obtained the office of Frate del Piombo; when he ceased to paint for profit; and was henceforward known by the name of Sebastian del Piombo. He lived in great esteem with pope Clement VII., whose portrait he painted with great power and fidelity; as well as that of the ingenious satirist Aretine; and those of many persons of rank and renown. He obtained great praise for having discovered a mode of preventing oil colours, employed on plaister, from becoming dark; which he did, by applying, in the first instance, a mixture of mastic and Grecian pitch. Having passed through a life of great honour and emolument to the age of 62, he then shared in the common fate of human nature, and died in the year 1547.

PIONEER, in *War*, a labourer employed in an army, to smooth the roads, pass the artillery along, and to dig lines and trenches, mines, and other works.

Menage derives the word from the Latin *peditores*, a diminutive of *pedites*. Bochart deduces it from the *Pæones*, a people of Asia, whose principal employment was to dig the earth in mines, &c.

Molt of the foreign regiments of artillery have half a company of pioneers well instructed in their business. Our regiments of infantry and cavalry have three or four pioneers each, provided with aprons, hatchets, saws, spades, and pick-axes. They have also a cap with a leathern crown, and a black bear-skin front, on which is the king's crest in white, on a red ground, and the number of the regiment on the back part of the cap.

PIONSAT, in *Geography*, a town of France, in the department of the Puy-de-Dome, and chief place of a canton, in the district of Riom; 22 miles N.W. of Riom. The place contains 1680, and the canton 8026 inhabitants, on a territory of 170 kilometres, in 10 communes.

PIONTAK, a town of the duchy of Warsaw; 20 miles E.S.E. of Lencicz.

PIONY, in *Botany*. See *PÆONIA*.

PIORAS *Fort and Village, Old*, in *Geography*, are situated in the north-west territory of America, on the west shore of Illinois river, and at the fourth end of Illinois lake; 210 miles from Mississippi river. The stockaded fort commands a fine prospect of the country to the eastward of the lake, to the point where the river enters it at the north end; to the westward are large meadows, and a level country full of swamps, and containing abundance of cherry, plum, and other fruit-trees. The lake, which is merely a dilatation of the river, $19\frac{1}{2}$ miles long, and 3 broad, contains plenty of fish, and particularly sturgeon and picannao. The Indians, at the treaty of Grenville, in 1795, ceded to the United States a tract of 12 miles square at this fort. N. lat. $40^{\circ} 53'$. W. long. $91^{\circ} 12' 30''$.

PIORIAS *Wintering Ground*, a tract of land in the Indiana territory, on the south-east side of Illinois river, about 40 miles above and north-east of the Great Cave, on the Mississippi, opposite to the mouth of the Missouri, and 27 below the island of St. Pierre. On a meadow, east of the river, many miles long, and five or six broad, are many small lakes, communicating with each other, and one of them with the Illinois river.

PIORIAS, an Indian nation of the Indiana territory, who, with the Mitchigamias, could furnish, about 40 years ago, 300 warriors. They occupy the parts near the settlements in the Illinois country. A tribe of this name inhabit a village on the Mississippi, a mile above fort Chartres. This tribe could furnish, about the same period, 170 warriors of the Piorias and Mitchigamias.

PIOSSASU, a town of France, in the department of the Po; 10 miles W.S.W. of Turin.

PIOZZI, **SIGNOR**, in *Biography*. Though we have adhered as closely as possible to the rule of confining our remarks on musical composers and performers to the dead, of whom an opinion may be given without fear of offence, if unfavourable, or of exciting envy by eulogies; yet signor Piozzi, though still living (1814), may be excepted from this rule, as he has long retired from all professional concerns, and as we had nothing but good to say of his talents.

He arrived in England about the year 1777. His voice was not sufficiently powerful for a theatre, or spacious concert-room; but as a chamber-singer, both his voice and style were exquisite. Previous to the arrival of Pacchierotti in England (1778), signor Piozzi, who heard him at Milan, gave no *l'avant gout* of his performance, by singing several airs after his manner, in a style that excited great ideas of his pathetic powers, and upon which signor Piozzi seems chiefly, and very judiciously, to have formed his own manner of singing.

PIP, in *Rural Economy*, a disease among poultry, consisting in a white thin skin, or film, growing upon or under the tip of the tongue, which hinders the feeding. It has been supposed to arise from the drinking of puddle-water, or eating filthy meat, by some; but this is not very probable. It is usually cured by pulling off the film with the fingers, and washing the part with a solution of common salt in pure water. It is sometimes written *pep*.

PIPA, in *Zoology*, a species of *Rana*; which see.

PIPA, in *Commerce*. See **PIPE**.

PIPAREA, in *Botany*, a name of Aublet's, of which no explanation is given; but this omission is of small importance, the genus being almost equally unintelligible. Aubl. Guian. v. 2. append. 30. Juss. 295.—Clas and order unknown. Nat. Ord. supposed by Jussieu to be akin to *Cistus*, or perhaps to his *Tiliaceae*.

Elf. Ch. Capsule triangular, of one cell, and three

valves. Seeds one, two, or three, clothed with cottony down, each inserted into a fleshy, white, fringed receptacle, attached to the middle of each valve.

1. **P. dentata**. Aubl. t. 386.—Gathered by Aublet in the forests of Guiana, bearing fruit in August. A small tree, whose trunk is four or five feet high, and four or five inches in diameter, with a reddish, wrinkled, rough bark. Wood hard, close-grained, whitish. Branches subdivided. Leaves alternate, nearly sessile, ovate, blunt-pointed, crenate, firm, seven inches long at the most, and three wide; smooth and shining above; clothed with short reddish down beneath; their midrib sending off numerous transverse veins. Stipulas small, awl-shaped, deciduous, in pairs at the base of the short footstalks. Fruit axillary, sessile, either solitary or in pairs, with two little scales at its base, consisting of a thin, brittle, red capsule, spotted with green, about as big as a filbert. The seeds are entirely covered with a very fine, pure white, cottony substance. Aublet never met with the flowers, nor has any subsequent traveller given any account of this plant.

PIPARS, in *Geography*, a town of Hindoostan, in the circar of Joodpour; 20 miles S.W. of Meerta.

PIPE, a close channel for the conveyance of water, or other fluids, is of such extensive use in building, &c. as to render the consideration of its materials, and best means of forming its joints, a matter of importance to architects and engineers, that they may give stability and durability to their work, at the least expence. Water-pipes are made of wood, iron, lead, copper, stone, or pottery; and each of these materials, in different situations, has its preference.

Wooden-pipes may be procured in all countries at a small expence, are easily made, and joined together; but the great objection is their want of strength to resist a strong pressure without breaking, and their liability to decay. For water-works they are usually made of elm, or alder; oak, though far preferable, being too expensive. They are best made from small trees of the proper size; and then the bark, being left on, is thought to preserve them. The passage is bored out by a long auger, turned round by one or two men; whilst the tree is supported in a convenient position on treffels, and bound fast down upon them by ropes, to which weights are attached.

In towns where water-works are established, the demand for pipes is such as to render this method too expensive; and machines are used to bore them, turned by horses, water, or steam-engines. The pipe-boring machine is extremely simple. A pit is first dug, similar to a saw-pit; on each side of this a long timber is fixed, and the two being united, at various points, by cross framing, forms the bed, on which the sledge slides backwards and forwards as great a distance as the length of the tree which is to be bored. The sledge is a frame of wood, upon which the tree is laid when it is to be bored, and is firmly held upon it by chains passed over it, and drawn exceedingly tight with windlasses fixed in the sledge. Wedges of wood are used to support it from rolling sideways, and to raise it up to such a height, that the borer will pass through the centre of the tree. The borer is fixed at the extremity of a spindle, supported by bearings, on blocks raised from the cross framing of the bed at one end, and which are adjusted, that the line of the borer will be exactly parallel to the bed and sledge: the spindle is put in motion by wheel-work from the mill, so as to revolve 30 or 40 times per minute. The sledge with the tree is advanced towards the borer by ropes, which are conducted over proper pulleys, from each end of the sledge, to the barrel of a wheel, with handles on its circumference, similar to the steering-wheel of a ship: therefore, a man, by turning

PIPE.

turning the wheel one way, advances the slider, with the tree towards the borer, which penetrates into the end of it; but on turning the wheel in an opposite direction, it is withdrawn, to clear the chips of wood. This is repeated till the pipe is bored through. The borer can be detached from the spindle, to employ another of greater or lesser diameter, when the pipes require it. The elm pipes employed in the streets of London for the distribution of water, are made by this means, except such trees as are crooked: these are bored by hand augers, because they must be pierced from both ends to meet in the middle, which the machine will not readily do.

The lengths of pipe are joined together, by enlarging the bore at one end in a conical form, with a sort of auger, and cutting the opposite end taper, to drive into the conical end of the adjacent pipe, which is hooped to prevent it from splitting. This method is a very bad one, very soon decaying, even when the taper end is fitted perfectly, because the thickness of the wood at the taper part is so very small. In the usual mode of fitting them, by merely shaping the conical part with the axe and drawing-knife, whilst the workmen are perhaps over shoes in mud, and exposed to bad weather, it is scarcely reasonable to expect them to be very attentive; but the joint is fitted in haste, and dispatched as quick as possible: the consequence is, that the conical part being correctly bored, whilst the taper is made to an irregular and more obtuse cone, the joint fits only at a very narrow point; but if well driven, will make a tight fitting at first, and, when buried, escapes detection; but in the course of a very few years, the vacant space round the end of the taper accumulates mud, which hastens the decay of the wood, and the joint fails. From these circumstances, the pavement of the streets is constantly broken up, the way impeded, and the supply of water suspended. The Society of Arts have, under these considerations, offered a handsome premium, for several years past, to procure a complete remedy for these defects. Mr. Hornblower proposed a tool, or bit, to form the taper end of the pipe, with the same certainty as the cone which is bored. It consisted of a wooden plug, fitted to the bore of the pipe, and having through its centre a hole, for the reception of a round iron rod or axis, which has a cross handle at the end, like an auger, to turn it round by. Near the handle, its size is sufficiently enlarged to have a mortise, for the admission of an iron arm, which can be fixed in it by a wedge. This arm turns down, and carries a steel knife, the edge of which, by the bending, stands inclined to the round rod, in the angle the conical taper is to have: therefore, by turning the handle round, the edge of the knife describes the surface of the cone, and cuts away the wood of the pipe to that form; the round rod, being of considerable length, can slide freely in the plug at the end of the pipe, and allow the cutter to be thrust up, to cut by degrees, till it reduces the taper. The use of this tool would ensure the perfect fitting of the joints; but still the plan is defective, as before mentioned, from the small quantity of wood round the joint. Another kind of joints have, therefore, been proposed: in these the adjacent ends of the pipes to be joined are both bored out, by a taper bit, to hollow cones; and the two are united by a short iron tube, which is made in form of two truncated cones joined at their bases, and of dimensions correspondent with the conical bases in the ends of the pipes. This plan is very far preferable to the former, both in strength and durability; and as the tubes are made of cast-iron, it is not an expensive one.

Messrs. Eckhardt and Lyon obtained a patent in 1806, for a method of making wooden pipes by separate staves,

resembling a barrel, but of less curvature, and greater proportional length, so as to approach near to a cylindrical form, particularly within side. They are to be bound by iron hoops, made fast either by driving them on from the ends, or by screwing the hoops together; the lengths are to be joined together, by forming one end of each taper, and enlarging the corresponding ends of others to receive them: the staves are to be fitted by tongues, rabbeting, or dovetailing. We have not heard of this method having been practised to any extent: it would, we think, be very expensive, and have all the defects of wood pipes; being liable to speedy decay, when buried in the ground. And it generally happens, that in their rotten or decayed parts they generate insects and animalculi in vast numbers; which may always be discovered in water that has passed through wood pipes or pumps, which have been long in use. Dr. Buchan observes, that such water becomes putrid by the corruption of the animal and vegetable bodies with which it abounds.

Iron-pipes are cast at the iron-founderies of any dimensions; and for durability and strength combined, are greatly superior to any other material: they may be procured in lengths of ten feet, and united by nuts and screws passed through flanches, cast on the ends of them. Most of the great Companies for supplying London with water have, within these few years past, adopted cast-iron pipes for their mains, and are daily increasing them, under the conviction that their permanency will compensate for the first expence. They are usually cast in lengths of ten feet, one end with an enlarged socket of sufficient size to receive the end of the next pipe. As these joints cannot be driven close, to fit like wooden joints, they require some cement. To apply this, they first caulk it, by driving a small quantity of hemp down to the bottom of the joint with a blunt chissel, and then fill the remainder of the socket with iron cement; which is a composition of borings or turnings of cast-iron, mixed up with sulphur and sal ammoniac. This is moistened with water, and rammed into the cavity; and the rapid oxydation of the iron borings unites them into one mass, and at the same time expands the bulk of the cement, so as to fill up all the space very closely. The hemp, first driven into the joint, is only to prevent the cement getting into the pipe, and to keep the water from it till it is set firmly; after which, the joint is as solid as any other part of the pipe. Another method, much used for large pipes, is to have two ears projecting from each pipe at the joint, through which screw-bolts are passed, to draw them close together. The joints are sometimes filled with lead run in, whilst melted; and others have used the Roman cement to bed the joints in.

Within these few years immense quantities of iron pipes have been laid in all parts of London, for the conveyance of water, which no sooner became generally known, than great prejudices were excited against them, under the idea that they would give the water a metallic taste, which would be injurious to the health of the inhabitants. This is clearly an error, as any one may ascertain, by examining an old cistern, or vessel of cast iron, which has only had fresh Thames water in it; and they will find it coated with a sort of japan, or smooth surface of a black colour, which is a very thin oxyd, and does not penetrate any depth: though if the water is of such a quality as to produce red rust, the iron is corroded very fast, but is still a very harmless mixture. Water having any lime in it, deposits a thin coat or incrustation within side iron pipes, and thus completely defends them from corrosion; nor is there any danger, as some have supposed, of this incrustation increasing

PIPE.

so as to stop the pipes in course of time, because the water only deposits the stony matter from the attraction of the iron, which being once covered with a slight thickness, the water has no longer access to the iron. We have heard of an expedient of putting lime into the water, when it was found that the water was so corrosive as to become tinged by running through iron pipes newly laid down. A rapid current of this lime-water being caused through the whole length for a few days, the pipes became coated with the calcareous matter. At first, after this, the fresh water tasted of lime, but it became pure in a short time, because, in the first instance, more lime was deposited than could be combined with the oxydated surface of the iron, and this excess would of course be carried away again by the fresh water, but no more.

Stone Pipes.—The prejudice the public at first entertained against iron pipes, induced many projectors to find out other substances, which would have the strength and durability of metal. Sir George Wright proposed stone, and invented a machine for cutting out cones from the hollow of the pipe. He first employs a boring or drilling machine, to pierce a small hole through the centre of the block of stone, in the axis of the intended pipe. Another machine is then used, consisting of a saw applied in a frame, which revolves on a round iron rod, passed through the central hole previously drilled: the frame gives the means of fixing the saw at any required distance from the rod, and attaching it firmly thereto at each end: its edge will of course, when turned round, describe the surface of a cylinder, of the diameter of the intended pipe. The saw and central rod are rather longer than the block of stone, which permits them to be moved backwards and forwards endways, to give the motion of sawing with sand and water in the usual manner. In their operation, the block of stone is placed with the rod horizontal; the saw is entered at another hole, previously drilled through the stone, and as the saw cuts, the central rod guides it round on a centre, till it separates the core all round, and this being taken out, leaves a pipe or tube. Sir George obtained a patent for this invention in 1805, and it was practised for some time, and many large stone pipes were laid; but great difficulties arose in making good joints: they were attempted by Roman cement, which adhered so well, as to make them perfect, if the pipes were well bedded; but the continual tremor of heavy carriages passing over them soon disturbed many joints, and broke the bond of the cement. Mr. Samuel Hill took out a patent in 1810, for uniting these pipes together at every joint by a collar of stone, into which the extremities of two pipes are made to fit, so that about two inches of each shall enter it, and reach to its centre, where they are to meet. A sufficient quantity of cement is to be spread on the ends of each pipe, and in the internal part of the collar, before they are inserted into it, to prevent water from passing through the joints. Although this obviates one difficulty, still the expence of stone pipes is prodigious; at least in London, where the price of materials alone, without any cost of workmanship, would be too great. In situations where that material is plentiful, they may be used, and the labour of making them will be reduced very low by a machine invented by Mr. Murdoch, and for which he had a patent in 1810: it is very superior to the above, which is only applicable to large pipes; besides, the trouble of previously drilling two small holes the whole length of the pipe is wholly saved.

When it is intended to form a pipe or hollow cylinder of stone by Mr. Murdoch's machine, instead of reducing the whole inside to powder, it is sawed in the form of a core, or solid cylinder, the diameter of which is about half an

inch less than the diameter of the inside bore of the pipe. In like manner, when a solid column or cylinder is to be formed, the outside and superfluous parts of the stone are taken away by a similar process, and the core forms the column or cylinder required. When the stones are large enough to leave the outside parts of a proper thickness, they may be used as pipes; or the cores cut out of large pipes may be used as columns, or formed into smaller pipes, so that in some cases several may be cut out one within another. The method by which these are formed is the following:

The block of stone, out of which the pipe is to be formed, is placed in a vertical position, and a plug of wood or metal is fixed in the top of the block, at the centre of the intended pipe; this plug has a hole in its centre, for receiving the lower pivot of a vertical spindle or axis, which is made longer than the pipe is required to be. The rod is of an uniform thickness, and made either square, triangular, or any other shape that will admit of sockets sliding freely up and down, without turning round upon it. On the upper part of this spindle a socket is fitted, having on the middle part of its outside a pulley or a small-toothed wheel, by which the axis or spindle may be turned round. The upper and lower extremities of this socket are cylindrical, and serve as gudgeons, upon which it turns in a frame, and steadies the axis. Near the lower end of the vertical axis a wheel with arms is fixed, having the circumference like a hoop two or three inches broad; and its diameter a little less than the diameter of the pipe to be bored: it fits to the inside of a tube of metal, which is attached to the spindle, and kept concentric with it, by being fitted over the wheel. The upper part of the spindle is perforated to a little below where the above-mentioned socket is fixed, and then the perforation comes out obliquely. The tube is of a diameter nearly equal to that of the pipe to be formed, and exceeding it in length about two feet: this pipe is made as truly cylindrical as possible, and is attached to the axis by another wheel across, similar to that at the bottom, which is fixed in the tube at the upper end, and fits upon the square spindle, to slide freely up and down, without turning round upon it; this tube being, as before-mentioned, guided by fitting on the wheel fixed at the lower part of the spindle. On the lower edge of the tube a rim of proper metal is fixed, which is so much thicker than the tube, that the groove it makes in the stone may admit the tube to move freely. This hoop being intended to grind or saw the stone, has its lower edge either left smooth, or formed like the saws used by stone-cutters. The wheel or cross, which is fixed on the vertical tube, near its upper end, has a small cord or chain fastened to one of its arms, and passes upwards through the perforation in the upper part of the axis, and then over a pulley fixed at a convenient distance above it: it serves to raise the tube on its axis when required. On the upper part of the tube weights are fixed, for the purpose of making it act more forcibly upon the stone, if necessary. When the apparatus is to be put in motion by the force of man, the above-mentioned pulley, fixed in the socket near the upper part of the axis, is generally made about double the diameter of the pipe to be bored, and a rope passes round it, each end of which is conducted over a vertical pulley, fixed at a convenient distance, on each side of the machine; by which means the ends of the rope turn downwards, and having handles fixed to them, are pulled alternately by a man at each end, so as to cause the tube to make a reciprocating rotative motion about its axis or spindle: or the apparatus may be put in motion by any other power, only if the pulley and cord be retained, a spring or a sufficient weight acts

at one end, while the power operates on the other by means of a crank, or other similar contrivance. Or, instead of the pulley, a toothed wheel or pinion is substituted, and acted upon by a reciprocating toothed wheel, belonging to the mill, engine, &c. connected with the moving power, or by a reciprocating rack or sector, put in motion by the same power or machinery. A cistern is placed at some convenient height above the tube, by means of which, a mixture of water and sand is conveyed into the tube, and forces its way under the saw, when in motion, and causes it to abrade or grind away the stone, and form in it a circular groove, concentric with the axis. As the groove becomes deeper, the water accumulates in the tube, and forces the sand with it under the saw and both are discharged over the outer edge of the tube, in the form of mud or sludge, and the motion of the tube may be thus continued as long as the moving power is maintained. When any circumstance causes this to stop, the tube must be drawn up by means of the cord and pulley for that purpose, or the sand will set fast round the tube, and will not be easily freed again.

Copper-pipes are too expensive to be employed except in particular situations. They are made of copper plate turned up and soldered, and are much used in distillers' work, because they can be tinned within, and then communicate no taint to what passes through them.

Lead-pipes are universally employed for all small water pipes, chiefly from the facility of bending them in any direction and soldering their joints. Although some kinds of water corrode the metal by degrees, this will not produce so much harm as iron under the same circumstances, but would be a most dangerous poison if it was used in sufficient quantities to have any effect at all.

The greatest proportion of the leaden pipes used in water-works, was, till of late years, made of sheet lead wrapped round an iron or wooden core, and the joint soldered up. The expense and trouble of this method was considerable, and the pipes thus made extremely liable to burst at the joint, particularly if bent with a sudden angle. These defects suggested the idea of casting the lead in the form of pipes, by which means the trouble of previously casting and laminating the lead into sheets would be spared, and also the uncertainty of the soldered joints. Such pipes are cast in an iron mould, made in two halves, forming, when put together, a hollow cylinder, of the size of the intended pipe. A core, or iron rod, the size of the bore of the pipe, is adapted to this hollow mould when the halves are put together, and secured by screws or wedges, so that it exactly occupies the centre of the hollow mould, leaving therefore an equal space all round between them. A spout, or entry for the admission of the melted lead, is made by a corresponding notch cut in each half of the mould, and at another place is a similar vent for the escape of the air. This mould is fixed down upon a long bench; and a rack, moved by toothed wheels and pinions, is fitted up at one end of it, in a line with the centre of the mould. A hook at the end of the rack, being put into an eye at the end of the core of the mould, affords the means of drawing out the core, when the pipe is cast round it by pouring the melted lead into the mould, with the core in it: when the lead is cold, the core is drawn out very nearly to the end of the pipe, by the rack and wheel-work before mentioned. The halves of the mould are then separated, and the pipe moved along in the mould, so that only an inch or two of its end remains in the mould, the halves of which are again fastened together with the core between them, and its end entered an inch or two into the first piece of pipe. The mould is now filled with melted lead, the heat of which fuses and unites it with the end of the first piece, so as to double

its length. The core is again drawn out a second time, and another length cast to the former. This method produces pipes of any length in one piece, but they are liable to have air-bubbles in them, which produce holes when the metal is thin, and the joinings of the different lengths are not always perfectly sound.

The method which is now very generally adopted, is to cast the lead in an iron mould, upon a cylindrical iron rod of the size for the bore of the intended pipe, the lead being three or four times the thickness of the intended pipe, and in short lengths, which are then drawn through holes in pieces of steel, in the manner of wire drawing, till the pipe is reduced to the intended thickness, and drawn out to the proper length. Another method is to reduce the pipe by repeatedly passing it through the two rollers of a flattening mill, in each of which a number of semi-circular notches are formed all round, so that the two rollers, when put together, have a number of circular cavities between them, which gradually diminish in diameter from one end of the rollers to the other. Drawings of such rollers will be found in our plates of *Iron Manufacture*. The pipe is first rolled between the largest of these cavities, then in a smaller, and so on to the last, which extends the pipe to its proper length, and diminishes its substance to the proper thickness, at the same time by condensing the metal hardens it, and makes a very strong tube with very little metal. Mr. John Wilkinson of Broseley, the celebrated iron manufacturer, took out a patent, in 1790, for the last mentioned method, which he practised on a very extensive scale: he was not, however, the original inventor, the same thing having been proposed, in 1728, by M. Fayolle; see "*Machines Approuvées par l'Académie Royale*," vol. v. p. 50. Since the expiration of this patent many manufactories of this article have been established, some employing rollers, and others the draw-bench, for extending the pipes.

We have given a representation of one of the latter machines in *Plate XL. Mechanics*. *Figs. 1 and 2* are sections of the mould for casting the pipes; A A is the bench, supported on legs like a stool in an inclined position; B, B, are the two halves of the mould, fitted into each other with double rebates, as shewn in the section *fig. 1*, that they may come together correctly, and are held by the screws D, D, fitted through pieces of iron E, E, fastened to the bench; the halves of the moulds have at each end a flat side beneath, which rests upon the iron plate connecting the two pieces E, E; F is the core, held in its position by collars at each end of the mould embracing it; G is the rack, and H I K the wheel-work for drawing out the core; *d* is the entry for the metal, raised up to the same level as the highest point the metal is intended to run into. The intention of the inclined position for the mould is, that the metal may run in at the lowest point of the mould, and expel the air as it rises, at a vent in the highest point of the mould, which is *e*. By this means the danger of air-bubbles in the pipe is avoided. The interior surface of the mould is bored out truly cylindrical, and the core being turned in the lathe, they are certain when put together to leave an equal space all round, a circumstance which is essential to form a good pipe, as the succeeding process of drawing will tend to make an error of this kind worse. The core, F, is seen in *fig. 2* to have a neck or smaller part at the end *d*: the treble or core *a g*, *fig. 3*, upon which the pipe is to be drawn, is of the same size, and has a similar neck, so that the pipe, when put upon it, fits it in every part, as is shewn in *fig. 3*, and the shoulder of the neck prevents the treble being drawn through the pipe in the direction from *g* to *a*, as it was put in by the opposite direction. Beyond the neck the treble has a notch cut in each side at *g*, leaving a neck;

PIPE.

a neck; and by this it is seized in a sort of claw belonging to the draw-bench, which is exhibited in *figs. 4 and 5*, the former being a plan, and the latter a section. In these *L, M*, are two strong timbers, bolted to uprights *N, O*, at one end of each, and to a cross beam, *W*, at the other end; the uprights support bearings for the gudgeons of a strong iron spindle, which has the cog-wheel, *k*, fixed upon its end, and is turned round by the pinion *l*, receiving a rotative motion from a steam-engine or water-wheel; *P* is a roller, fitted on the spindle so as to slip round freely upon it; it has two claws affixed into it at one end, which are seized by the ends of an iron bar, *m*, fixed fast upon the spindle. By this means, when the roller is thrust towards *m*, it is engaged with its arms, and compelled to turn round with the spindle, but when drawn back from *m*, it is at liberty to slip round independent of it; *Q* is a lever affixed to a vertical axis; it is forked at the end, and embraces a collar upon the end of the roller, so as to draw it backwards or forwards, and by this means engage or disengage it from the spindle at pleasure; *R* is another lever on the same spindle, to the end whereof a long rod, *S*, is jointed, and this has several handles fixed to it, as shewn in *fig. 5*, by which it can be moved, and the machine stopped or put in motion by a man standing at any part of the long bench *L M*; the roller, *P*, has a pair of spiral grooves formed on its circumference, for the reception of two chains, *n, n*, which wind upon it; the ends of these chains are hooked to a little carriage, *p*, running upon two wheels, and having in its hinder part a fork or double claw, to catch in the notches at the end of the treble *T*, also shewn in *fig. 3*; *X* is a cast-iron frame, securely bolted down upon the cross beam *W*; it has a notch in its upright side, which is nearest the roller, to allow the treble and pipe to pass through, but at the same time forms a lodgment for the steel plate, through which the pipe is to be drawn. The workmen are provided with a great number of these plates, one of which is shewn in *fig. 6*; they are called whirtles: the sizes of the holes through them diminish very gradually, from the diameter of the rough cast pipe, to the size to which it is intended to be reduced. The holes through them are made rounding at each side, as is shewn in the section *Z*, *fig. 6*, to facilitate the exit and entry of the pipe. The bench is continued beyond the beam *W*, and has a number of rollers in it, to support the pipe as it is drawn along.

The process of drawing is as follows: the lead pipe being fitted upon the treble, as in *fig. 3*, is laid upon the rollers in the bench, and the end of the treble being put through the largest of the set of whirtles, its end is hooked into the clays in the carriage *p*, and the whirtle lodged against the cheeks of the frame *X*: the rod, *S*, is now pulled, which engages the roller with the spindle (supposed to be all the while in motion); this winds up the double chains *n*, drawing the pipe through the whirtle, by which it diminishes its size and lengthens it out: when the pipe is drawn quite through, the roller is cast off by pushing the rod *S*; the treble is unhooked from the carriage, and pushed back upon the rollers in the bench to its former position; another smaller whirtle is put on; the carriage is drawn back by hand (the roller turning round on its spindle), and the pipe is drawn through it as before. In this manner the business proceeds till the pipe is finished.

Sometimes the pipe is drawn through twelve sized whirtles in this case; the second time, and also the last time but one, it is drawn through a whirtle such as *Y*, *fig. 6*; it is not rounded off at the entrance, but having a sharp edge, it cuts off shavings from the surface of the lead, making it perfectly smooth and true: this makes it pass more easily through the succeeding whirtles. Lead pipes are by this

process drawn out to ten or twelve-foot lengths, three of which are united into one, by what is called *burning*. For this purpose an iron core is put through one pipe, and entered a few inches into the other: a small iron mould is now put together in two halves over the ends of the two pipes which are brought in contact, the mould exactly fitting both; melted lead is poured into the mould, and it runs out again at a hole in the bottom. This is continued till it is supposed the heat of the lead has fused the ends of both the pipes; the hole in the bottom is then stopped by a slider for the purpose, and the mould remains full: when cold it is taken off, and the pipes are perfectly united. The core is now withdrawn, to facilitate which, it only fits the bore of the pipe at a few inches of the end. These joints are very good if the pipe remains straight, but are apt to leak if a bend is made at one of them.

In 1804, Mr. Alderfon took out a patent for lead pipes which were to be lined with tin, for the conveyance of beer, water, or other fluids which were in danger of receiving a taint from the corrosion of the lead. This he accomplished by casting a lead pipe in the manner above-described, then withdrawing the core, and throwing into the pipe a small quantity of powdered rosin. Another core smaller than the former is next inserted into the centre of the pipe, and melted tin poured in to fill up the space. The pipes are cast in a vertical position, and the rosin melting by the heat floats upon the surface of the tin, and acts as a flux to unite it with the lead. This pipe of lead, lined with tin, is now to be drawn or rolled to length, as before-mentioned. We are informed Mr. Alderfon employs rollers to extend them instead of the draw-bench.

Mr. Bramah's method of making lead pipes is very ingenious; it is performed by a process of pumping or forcing the metal, in its fluid state, through proper moulds. A boiler or kettle is fitted up over a fire-grate, with flues for the fusion of the metal; in the centre of this boiler a force pump is fixed up, its suction valve drawing in the melted lead contained in the boiler: the forcing pipe of the pump proceeds through the side of the boiler, and conducts the lead to the mould, which is fixed on the end of the pipe outside of the boiler: it consists of a tube, bored perfectly smooth and cylindrical, its interior diameter being equal to the outside of the pipe intended to be made; the end of the mould nearest the boiler expands into a conical mouth, larger than the mould itself, and across this widest part a cross bar is fixed, to support a core or mandrel, of a diameter equal to the bore of the intended pipe, and situated exactly in the centre of the mould, leaving an equal space all round between them: the core is slightly conical, being rather less at its extremity, which terminates at the same length with the external mould. There must be sufficient openings left at the sides of the cross bar supporting the core, to allow the lead to pass freely by, that it may unite again after passing the cross and completely fill the mould. The mould passes through one of the fire flues surrounding the boiler, that it may be kept so hot as to procure the lead in its fluid state, till it arrives nearly at the point of the mould, which is immersed in a cistern of hot water. The operation is simple: the pump, being worked, forces the lead through the mould, the heat and length of which are so regulated, that the lead may chill a little before it quits the extremity of the mould, and issues forth in a solid state into the water cistern, forming a pipe of any length. Mr. Bramah took out a patent for this method in 1797.

Pipes of pottery ware are usually made of that coarse kind of brown stone pot, which is very hard and durable; they can only be made in short lengths, and have one end enlarged

to receive others. To close the joints tow and pitch are used, but they can never be made to bear any pressure, are liable to be broken by accident, and being very expensive, have no other recommendation than preserving the purity of the water they convey.

We have seen some water conduits from an old Roman building, which were very slight pottery tubes, buried in a mass of mortar, that by ages had acquired a hardness and closeness sufficient to resist a strong pressure.

In 1808 Mr. W. Bell obtained a patent for a new kind of pipes for conveying water, which were to be made of such substances as to give no taint to the water passing through them. He proposed tubes of porcelain pottery, and various compositions which are vitrifiable, and are not liable to corrosion or decay: these tubes are formed in such a way at the ends as to fit one within the other, and are to be made water tight by cement; they are to be enclosed in cast-iron cases, to give them strength to resist the internal pressure of water, as well as to defend them from accidental violence; or the cases may be made of wood.

PIPE, Tobacco, an implement used in the smoking of tobacco, consisting of a long tube, made of a particular kind of clay baked hard: at one end a little cavity or furnace is formed, called the *bowl*, which is for the reception of the tobacco when burning, and the fumes are drawn by the mouth through the other end of the tube. The making of tobacco pipes forms a considerable trade in London and other great towns; they are made of various fashions, long, short, plain, worked, white, varnished, unvarnished, and of various colours, but the same process is followed for all of them. The clay is found in the isle of Purbeck, in Dorsetshire, and is distinguished from others by its perfect white colour, and its great adhesion to the tongue when baked, occasioned by its great affinity for water: even in the raw state it has this property in a slight degree. The clay is prepared by dissolving it in water in large pits, and the solution being well stirred, is run off into another pit, where it deposits the clay, which, when the water has become clear and run off, is taken up for use, all impurities of small stones, sand, &c. being separated from it and left in the first pit. The clay is now divided into portions, each sufficient to form one pipe, which are rolled on a table, under the hand, into long rolls, each with a bulb at the end, to form the bowl; and these are laid by a day or two, to dry sufficiently for the pressing. This is done in an iron mould, consisting of two halves, which when put together leave a cavity of the shape of a pipe; a wire is thrust up the roll of clay, to form the bore of the pipe, and in this state it is placed between the two halves of the mould, which are then put into a kind of press or vice, by the screw of which the two halves are forced together, and the figure of the pipe imprinted on the clay included between them; a lever is next brought down, which is so situated as to introduce a stopper into the bowl of the pipe whilst still in the mould, and force it down sufficiently to form the cavity thereof: the wire is thrust backwards and forwards, to prick the tube completely into the bowl; it is then wholly withdrawn, the parts of the mould separated, and the pipe taken out, the superfluous clay removed with a knife, and they are laid up to dry a day or two, after which they are scraped and polished with a piece of hard wood, the tubes of the pipes curved as they are intended to be, and they are then carried to the furnace to bake, which is done in seven or eight hours for fifty gross of pipes. This furnace is fully described at the end of our article **FURNACE**.

The Turks use pipes of three or four feet in length, made of rushes, or of wood, bored at the end; they have a

bowl or pot of baked earth to contain the tobacco, which they separate from the tube when they leave off smoking. To make the tube tight, some kinds are made of spiral wire covered with leather. This at the same time leaves them flexible, and the bowl can stand on the ground, whilst the smoker inhales its fumes through an ivory or silver mouth-piece at the end of the tube. Of this kind is the *hookah*, or *boukar*, used by the luxurious East Indians; it is a complete furnace or chafing-dish, with grate-bars, ash-pit, &c.; and has a tight cover over the top, with one of these flexible pipes attached to it. An officer of the court of a petty eastern prince is called *boukar boudar*, and is solely employed in managing this machine; which, having lighted and prepared, he presents the mouth-piece of the tube to his master after his dinner. In some instances, the bowl is kept in an adjacent closet, the pipe being conducted through a hole in the wall. Some of those which are most complete have another peculiarity; the smoke, before it goes into the tube, is made to pass under water, by bubbling up through it. This is found to give the smoke a mild and agreeable flavour, by depriving it of its acrid and pungent taste; and, indeed, it is for the same end of condensing these particles, that the tubes are made of such great length. We are not informed how the smoke is made to pass under the water, but have seen a simple experiment, which any one may try, to experience the improvement of the smoke by this process. Procure a common decanter or glass bottle, fill it half full of water, and fit a cork to it, which has two holes made through it by burning, sufficiently large to admit tightly the tube of a tobacco pipe: in one of the holes fit a pipe with a bowl, the tube end projecting so far down into the bottle, that it will be an inch below the surface of the water: into the other hole, fit a pipe without a bowl, not reaching to the water, but sufficiently curved or inclined to come conveniently to the mouth. Make all the joints tight by wax, fill the bowl of the pipe with tobacco, and light it; then by sucking air through the mouth-pipe, it will be drawn out of the bottle, and rarefy that within; the atmospheric air then presses through the burning tobacco in the bowl of the pipe, and carries the smoke down the tube through the water, and it rises in bubbles to the surface of the water in the bottle, from whence it can be inhaled through the mouth-pipe, by continuing to suck at it. The smoke is by this process cooled, and rendered very agreeable, by the separation of certain principles which are of a very unpleasant flavour: the existence of these principles will be shewn by the water in the bottle becoming yellow in a short time, and having a very disagreeable taste. This method of smoking may be useful to invalid smokers, who from cough, or inflammation of the lungs, are unable to continue a practice which, by long habit, has become quite an essential comfort to them.

PIPE, in Commerce, a measure of wine in England, Spain, and Portugal. (See **MEASURE**.) The pipe is = $1\frac{1}{2}$ puncheon = 2 hogheads = 3 tierces = 126 gallons = 504 quarts = 1008 pints; and 2 pipes are equal to a tun of wine. The standard gauge for foreign wines at the custom-house of London is as follows: the pipe of port is 138 gallons; of Lisbon, 140; of Madeira, 110; of Barcelona, 120; of Vidonia, 120. The butt of sherry is 130 gallons, and of mountain, 120. The hoghead of claret is 58 gallons, and of tent 63. The am of hock is 36 gallons. The gallon used here is seven inches in diameter, and six inches deep. The tonalada of Lisbon is 2 pipas; the pipa is 26 almudes, 312 canadas, or 1248 quartillos. The barrel is 18 almudes. The pipe of the standard gauge of Lisbon at the London custom-house is reckoned at 31 almudes, and the almude

almude at $4\frac{1}{2}$ English gallons nearly. A pipe in Spain is 27 arrobas of wine, or $34\frac{1}{2}$ of oil; and as a Spanish botta contains 30 arrobas of wine, or $38\frac{1}{2}$ of oil, the botta is = $127\frac{1}{2}$ English gallons, and the pipe $114\frac{3}{4}$.

PIPE, *Pipa*, in *Law*, is a roll in the exchequer, called also the *great roll*.

PIPE-Office, is an office in which a person called the *clerk of the pipe*, makes out leases of crown lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer.

Clerk of the pipe makes up all accounts of sheriffs, &c. and gives the accomptants their *quietus est*. To this office are brought all accounts which pass the remembrancer's office, and remain there; that if any stated debt be due from any person, the same may be drawn down into the great roll of the pipe, from the form of which he derives his name; upon which the comptroller issues out a writ, called the "summons of the pipe," for recovery thereof. And if there be no goods and chattels, the clerk then draws down the debts to the lord-treasurer's remembrancer, to write estreats against their lands.

All tallies, which vouch the payment of any sum contained in such accompts, are examined, and allowed, by the chief *secretary of the pipe*.

Besides the chief clerk, and his deputy, in this office are a first and second secondary, six attornies, or sworn clerks, and a comptroller, deputy and clerk, board-end clerks, and bag-bearer.

PIPE, in *Mining*, is where the ore runs forwards endways in a hole, and doth not sink downwards, or in a vein.

PIPE, *Air*. See AIR-PIPE.

PIPE, *Bag*. See BAG-PIPE.

PIPE-Clay. See CLAY.

PIPE-Clay and *Whiting*, in *Military Language*, a composition which soldiers use for the purpose of keeping their cross-belts, &c. clean. Every soldier belonging to the infantry of the line, and to the fencible infantry serving at home, has 4s. 4d. annually stopped from his pay for supplying himself with this composition.

PIPE-Drains, in *Agriculture*, such as are made in the more superficial parts of the earth, as a foot or more from the surface, by means of some sort of tool or implement, such as a thick iron spike, pin, or bolt, which is drawn through the ground in a horizontal manner at such depths. The improved mole plough is a very good tool for effecting these purposes, and is that which is most commonly employed in the business.

This is an excellent method of management for cold retentive grass lands, which lie in too flat and swampy a manner to shoot off their surface waters, with any degree of readiness, and which are free from stones. But though it may be found of general benefit in these cases, it is more especially so, it is conceived by some, for moist sheep pastures; it has also been found useful in some instances in arable land. When it is performed by the plough just noticed, the great strength and weight of draught which are required, especially where the older sorts of these ploughs are had recourse to, may form some objection to it. These tools have, however, much merit, and are very simple in their constructions, particularly the improved kinds, which only demand a little power of draught. See MOLE PLOUGH.

PIPE-Fish, in *Ichthyology*. See ACUS and SYNGNATHUS *Typhle*.

PIPE, *Horn*. See HORN-PIPE.

PIPES, *Organ*. See ORGAN.

PIPE, *Tail*, in *Gunnery*, a small brass pipe fixed at the swell of the musket, which receives the ram-rod.

PIPE, *Trumpet*, a small brass pipe near the muzzle of the firelock, through which the ram-rod is let down; so called from its resemblance to the mouth of a trumpet. The Prussians have no pipes to their muskets; the ram-rod being received into a cylinder which runs parallel with the barrel.

PIPE-Tree, in *Botany*. See PHILADELPHUS and LILAC.

PIPE-Tree, *Pudding*. See CASSIA.

PIPELGONG, in *Geography*, a town of Hindoostan, in Baglana; 14 miles N.W. of Chandor.—Also, a town of Hindoostan, in the circar of Aurungabad; 32 miles W. of Aurungabad.

PIPELO, a town of Hindoostan, in the circar of Rantampour; 33 miles W.S.W. of Rantampour.

PIPEMAKER'S CREEK, a river of the state of Georgia, which runs into the Savannah, N. lat. $32^{\circ} 8'$. W. long. $81^{\circ} 15'$.

PIPER, in *Botany*, Pepper, is enumerated by Linnæus, among the Greek names of doubtful origin. The Greek $\piειπειν$ is generally supposed to have been derived from $\piειπειν$, to cook, or digest. But the best authors give it as a primitive word; and professor Martyn rightly suggests that it is probably of Indian origin. De Theis also observes, that as the Greeks derived the knowledge and use of pepper from the oriental nations, the source of its name is to be sought in their languages, and its appellation in Arabic, *bábary*, is the evident original of $\piειπειν$.—Linn. Gen. 19. Schreb. 26. Willd. Sp. Pl. v. 1. 159. Vahl. Enum. v. 1. 312. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 69. Juss. 405. Lamarek Illustr. t. 23. Gærtn. t. 92. (Peperomia; Fl. Peruv. v. 1. 29. Saururus; Plum. Gen. 51. t. 12.)—Class and order, *Diandria Trigynia*. Nat. Ord. *Piperitæ*, Linn. *Urticæ*, Juss.

Gen. Ch. Cal. none. Cor. none. Stam. Filaments none; anthers two, opposite, at the base of the germen, roundish. Pist. Germen larger than the anthers, ovate; style none; stigmas from one to three, rough. Peric. Berry roundish, of one cell. Seed solitary, globose.

Eff. Ch. Calyx none. Corolla none. Berry with one seed.

A very extensive and singular tropical genus, remarkable for the simplicity of its flowers, which almost vies with that of the *Hippuris*. The number of *stamens* however is, in some cases, more than two, and in some the *stigma* is solitary. Several botanists have taken the *flower* to be gynandrous, because, at a very early period, before the germen is fully formed, the two *anthers* look as if seated on its summit, close to the *stigma*; but Jussieu well observes that they become lateral, or rather inferior, as it advances towards maturity. Linnæus has but twenty species of *Piper* in the second edition of Sp. Pl. to which five only are added in Syst. Veg. ed. 14. Willdenow has 52; but the most complete botanical view of this genus is found in Vahl's Enum. Plant., where 136 species are defined, and well described. This author properly unites the *Piper* and *Peperomia* of the Flora Peruviana, there being no solid generic difference between them; and he gives the following excellent sketch of the habit.

Stem round. Leaves simple, undivided, entire. Spikes lateral and terminal, stalked, simple, round. Flowers minute, crowded. Sheaths deciduous. In the first section, consisting of 73 species, the stem is shrubby, climbing, branched, jointed; the joints more or less knotty, and often sending forth roots: leaves stalked, alternate; some of them furnished with many nerves, proceeding, in alternate order, from the main rib, (Vahl terms such species *venoso-nervosi*); others having almost all the nerves originating from the base of the leaf (these he calls *nervosi*): footstalks channelled,

with a clasping base: *spikes* opposite to the leaves, and mostly solitary. The second section comprises 60 species, whose *stem* is herbaceous, fleshy, jointed, not knotty: *spikes* either axillary or terminal. The third section has but two species, distinguished by having no *stem*. The fourth contains one doubtful species only, *P. pinnatum* of Loureiro, Cochin. 31, whose *leaves* are pinnate, *stem* prickly, and *flowers* unknown, so that it probably belongs to some other genus.

We shall follow Vahl's arrangement, in selecting a few examples.

P. aequale. Vahl n. 10. Ecl. Amer. v. 1. 4.—“Leaves elliptic-lanceolate, attenuated, smooth; equal at the base; without dots beneath. Spikes straight.”—Native of the West Indies. We have it from Dr. Swartz. The *branches* are polished, somewhat zigzag, knotty at the joints. *Leaves* four inches long, we should rather call them precisely ovate, and pointed, very smooth, with many lateral curved ribs, springing from the main one, and connected by fine interbranching veins. *Spikes* an inch or more in length, exactly cylindrical, obtuse, solitary, opposite to each leaf, their *stalks* about the length of the *footstalks*, which is usually a quarter of an inch.

P. aduncum. Hooked Pepper, or Spanish Elder. Linn. Sp. Pl. 41. Vahl n. 24. Willd. n. 17. Ait. n. 6. Jacq. Ic. Rar. t. 210.—Leaves ovate-oblong, or elliptic, pointed, rough; unequal at the base. Spikes hooked.—Native of the West Indies, as well as of the continent of South America. The *leaves* are a span long, rough on both sides to the touch, like a fine file, with many straight transverse ribs. *Spikes* three inches long, remarkably incurved. *Flowers* regularly whorled. Sloane says in his History of Jamaica, v. 1. 135, that the *root* is very famous, resembling ginger in taste, colour, and smell, and when fresh not inferior to it.

P. aristolochoides. Lamarck Illustr. 80. Vahl n. 43.—Leaves heart-shaped, acute, dotted with numerous radiating ribs. Footstalks bordered. Spikes axillary, somewhat aggregate, from a lanceolate sheath. Gathered by Commerçon in the island of Mauritius. The *leaves* are the size and shape of *Aristolochia Sipo*; the *stalks* and *branches* roughish, but we do not find them villous. *Spikes* small, two or more together. This plant is very near Forster's *methylicum*, Vahl n. 66, and perhaps not different from it.

P. nigrum. Black Pepper. Linn. Sp. Pl. 40. Vahl n. 52. Willd. n. 1. Ait. n. 1. Mill. Illustr. t. 5. Woodv. Med. Bot. t. 187. Ger. Em. 1538.—Leaves broad-ovate, pointed, coriaceous, smooth, with seven ribs. Joints of the stem tumid.—Native of the East Indies. Said in Hort. Kew. to have been introduced into the English stores, in 1790, by Messrs. Lee and Kennedy. The three central ribs, in our specimens, are combined at the base for about an inch. M. Poiret, in Lamarck's Dict. v. 5. 458, justly remarks that J. Miller alone, in his Illustr. of the Linn. Syst. has described a *cerella*, or *calyx*, of one leaf, with three notches, in this plant. No person has been able to verify this representation, nor is it known whence Miller procured his drawing, unless perhaps from his son, a botanical artist, who visited India. His plate has always been considered as a valuable addition to the history of a plant so imperfectly known to botanists, and it is pity any uncertainty should be attached thereto. Woodville's figure is a copy of Miller's. More than one species perhaps has been confounded under *P. nigrum*, particularly the *stylefere* of Loureiro, Lamarck, and Vahl n. 45; nor have we materials to clear up this confusion.

P. Cubeba. Cubebs. Linn. Suppl. 90. Vahl n. 61.

Willd. n. 3. Gaertn. t. 92. (*Piper caudatum*; Ger. Em. 1540. Cubeba; Woodv. Med. Bot. v. 4. 165).—Leaves elliptic-lanceolate, pointed, smooth, five-ribbed; contracted and unequal at the base; the middle ribs combined half way up. Berries on partial stalks. Native of Sierra Leone, from whence we have specimens, gathered by professor Afzelius and his companion Borone, in leaf and fruit; so that no further doubt can remain as to the identity of the plant. There are others, without name or mark, in the Linnæan herbarium. We know of no figure of any part except the *fruit*, as above cited. The *stem* is round, smooth, zig-zag, striated, with rather tumid joints. *Leaves* two or three inches long, and one broad, solitary at each joint, on short stalks; furnished with three principal ribs from the base, and with two more, which spring very irregularly and variously from the central one, towards the middle of the leaf. The base of the *leaves* in the Linnæan specimen is more dilated, and visibly unequal, than in those from Sierra Leone, but we scarcely think it indicates a specific difference. The *clusters* are two inches long; partial stalks half an inch.

The species of Vahl's second section are usually of humble growth, and a shining, pellucid, succulent habit. Such is

P. obtusifolium. Blunt-leaved Pepper. Linn. Sp. Pl. 42. Willd. n. 31. Vahl n. 79. Ait. n. 13. Trew Ehret. t. 96.—Leaves obovate; ribless beneath.—Native of the West Indies. The Linnæan specimen came from Jamaica. Vahl confounds with this the *chusifolium*, Jacq. Ic. Rar. t. 212, but they are kept separate in Hort. Kew. The *stem* is most spotted in *obtusifolium*; the *leaves* darker in *chusifolium*, with more conspicuous lateral ribs. These species and many others of this section, want a thorough investigation, and a careful comparison with each other, to be well understood; neither is the whole genus so completely settled as could be wished, notwithstanding the labours of Vahl, which have not extended sufficiently to the synonyms.

PIPER, in Gardening, contains plants of the herbaceous, shrubby, perennial, exotic kinds, of which the species cultivated are; the black pepper (*P. nigrum*); the rough-leaved pepper (*P. amalago*); the long pepper (*P. longum*); the intoxicating pepper, or ava (*P. methylicum*); the netted-leaved pepper (*P. reticulatum*); the hooked-spiked pepper (*P. aduncum*); the pellucid-leaved pepper (*P. pellucidum*); and the blunt-leaved pepper (*P. obtusifolium*).

On the first fort Martyn observes, that “white pepper was formerly thought to be a different species from the black; but it is nothing more than the ripe berries deprived of their skin, by steeping them about a fortnight in water; after which they are dried in the sun. The berries falling to the ground when over-ripe, lose their outer coat, and are sold as an inferior sort of white pepper.”

Method of Culture.—All these plants may be increased by seeds, procured fresh from the countries where the plants grow naturally, which should be sown upon a good hot-bed in the spring; and when the plants come up and are fit to transplant, be each put into a separate small pot filled with light fresh earth, and replunged into a hot-bed of tanners' bark, shading them every day from the sun till they have taken fresh root, when they must be treated in the same way as other tender exotic plants, admitting fresh air to them daily in proportion to the warmth of the season, to prevent their drawing up weak; and when the nights are cold the glasses of the hot-bed should be covered with mats.

They all require the constant protection of a hot-house.

As the stalks of most of them are tender when young, they should not have much wet, which rots them; and when water is given it must be with caution, not to beat down

down the plants; for when that is the case they seldom rise again afterwards.

In some of the forts they may be raised from layers or cuttings.

In the after-management of the plants, they must be plunged into the tan-bed of the bark-stove in the autumn, and during the winter be sparingly watered; they require the same warmth as the coffee-tree. In the summer a large share of fresh air must be admitted in hot weather, and they must be constantly kept in the stove, as already suggested.

They afford ornament and variety in stove collections.

PIPER *Chiapa*, in *Botany*, a name given by some authors to the clove-berry-tree, or cassia caryophyllata.

PIPER, *Jamaica*. See MYRTUS *Pimenta*.

PIPER *Nigrorum*, *Negro pepper*. The plant called at present by this name is the *capsicum*, or *Guinea pepper*, a remarkable herb, bearing large pods as red as coral, of which the Cayenne butter is made in America. But this is not the plant that was anciently known by this name. Avicenna and Serapion both mention a plant, which they call *fulful alsuaden*, the English of which is, the *pepper of the black people*. But this was properly what has been since called the *Ethiopian pepper*; a sort of hot seeds approaching to the nature of the common pepper, and containing several together in pods.

It is not easy, from the accounts we have left, to say what it is; but they have left description enough of it for us to say what it is not, and to find that they have all been mistaken, who have supposed it to be either the root tarfi, or the bulbous of the Arabians, which last was as large as a pear. See CAPSICUM.

PIPER *Tavasci*, the clove-berry-tree, or cassia caryophyllata; a tree whose bark is used in medicine.

PIPER, *Sand*, in *Ornithology*. See ARENARIA and TRINGA *Interpres*.

PIPER, in *Ichthyology*, the English name of a species of *trigla*, called by the generality of authors *lyra*. See TRIGLA *Lyra*.

PIPERAH, in *Geography*, a town of Hindoostan, in Bahar; 22 miles S.S.W. of Patna.

PIPERAPIUM, an old name of a plant found in Apuleius, and said to have its name from its heat to the taste; which was so offensive to the bees, that if a piece of it were hung up in the hive, it would drive them all out.

This is a very strange account: and as we meet with nothing to countenance it in any other author, there is reason to suspect it to be an error; and there seems this foundation for it. The acorus root is said by Dioscorides to be the root of a plant allied to the papyrus, or paper-reed of the river Nile; and is thence called by that author *papyraceous*. Avicenna and Serapion copy this, and liken the acorus plant to the papyrus; but in all the copies of the Greek author, it is often found written *πυπερριον*. This word *peperacion* may have been formed by Apuleius into *piperapium*, by way of amendment, and all the rest might be occasioned by this.

PIPERI, in *Geography*, a small island in the Grecian archipelago; six miles N. of Serpho.

PIPERIDGE TREE, in *Botany*. See BERBERIS.

PIPERINO, in *Mineralogy*, a substance that seems to be a concretion of volcanic ashes, and is said to be that which covers Pompeii. Its colour, grey, or reddish-brown; its lustre and transparency, 0; its fracture earthy, contains fragments of white marble, feldspar, mica, garnets, fcoriz, gypsum, thori, granite, &c.; its hardness, 6; sometimes magnetic, sometimes not.

It seems to differ from tufas, in containing more heterogeneities, being in fact a kind of porphyry or breccia, and

being more easily decomposed by exposure to moisture and the open air, but if preserved from moisture, it hardens when exposed to the air. Kirwan.

PIPERITIS, in *Botany*, a name given by some authors to the momordica, or male balsam apple.

PIPERIVORA Avis, in *Ornithology*, a name given by some authors to the toucan, or Brazilian magpye, from its feeding on pepper.

PIPERNO, in *Geography*, a town of Italy, in the Campagna di Roma, formerly the see of a bishop, but in 1225, on account of its poverty, united to Terracina. It was built out of the ruins of the ancient *Privernum*, which see; nine miles N.N.W. of Terracina.

PIPEROONE, a town of Hindoostan, in Bahar; 25 miles N. of Durbungah.

PIPERY, a town of Hindoostan, in Candeish; 32 miles S.S.E. of Chuprah.

PIPILE, in *Ornithology*, a species of *Penelope*; which see.

PIPING, in *Sea Language*. See CALL.

PIPING-Tree, in *Geography*, a town of America, in Virginia; nine miles E. of Newcastle.

PIPIRI, in *Ornithology*, a name given by Buffon to the *Lanius Tyrannus*; which see.

PIPISTRELLUS, in *Zoology*, a species of *Vespertilio*; which see.

PIPLERCHE, in *Ornithology*. See ALAUDA *Cristata*.

PIPLEY, in *Geography*, a town of Hindoostan, in Baglana; six miles N.W. of Bahbelgong.—Also, a town of Hindoostan, in the country of Berar; 18 miles N. of Jafferabad.—Also, a town of Hindoostan, in Bengal, near the borders of Orissa, on a branch of the Ganges, and formerly a place of trade, having an English and Dutch factory; but the trade declined, and the factories were removed to Hoogly and Calcutta; 22 miles N.E. of Balafore.

PIPPARAH, a town of Hindoostan, in Oude; 42 miles N.W. of Lucknow.—Also, a town of Hindoostan, in Oude; 48 miles E. of Bahraitch.

PIPPA, the *Manakin*, in *Ornithology*, a genus of birds of the order Passeres. The generic character is; bill short, strong, hard, nearly triangular at the base, and slightly incurved at the tip; the nostrils are naked, the feet formed for walking, the tail is short. These birds are very similar to the genus of Titmice, and are almost all peculiar to South America. In Gmelin there are thirty-one species enumerated; Latham mentions but twenty-five.

Species.

RUPICOLA; Rock Manakin. Crest erect, edged with purple; the body is of a saffron colour; the tail-coverts are truncate. It inhabits the rocky parts of South America, and is the size of a small pigeon. It is extremely shy, but may be tamed if taken very young; it feeds on small wild fruits, and builds in the clefts of the most remote rocks. It lays two white eggs at a time. The female, and the male also when young, are brown; the lower wing-coverts are rufous and orange.

PERUVIANA; Peruvian Manakin. Body saffron-red; greater wing-coverts cinereous; quill and tail-feathers black; the coverts of the latter are not truncate. It is a native of Peru, and of the same size as the last.

PAREOLA; Blue-backed Manakin. Crest blood-red, body black; back blue. It inhabits South America, and is four inches and a half long.

SUPERBA; Superb Manakin. Deep black; middle feathers of the crown longish, and of a flame colour; beneath the wings are pale blue lunular blotches; primary quill-feathers

feathers brownish. It is larger than the *Aureola*, to be noticed hereafter.

CRISTATA; Purple Manakin. Crest pale yellow; body purple. It inhabits Brazil and New Spain, and is three inches and a half long.

PICICITLI; Mexican Manakin. Cinereous; head and neck black; round the eyes is a whitish spot, which ends in a point at the breast. It is very small, and found in Mexico.

RUBETRA; Yellow Manakin. Crest pale yellow; body testaceous; quill and tail-feathers blue. It is found in Brazil and Cayenne. The bill is yellow; the chin brown, and the neck is marked with a golden colour.

TORQUATA; Collared Manakin. Black; head scarlet; quill feathers and coverts blue. It inhabits Brazil, and is about three inches and a half long.

MIACATOTOTLI; New Spain Manakin. Black, with a few whitish feathers; belly pale; wings and tail beneath cinereous.

PUNCTATA; Speckled Manakin. Greyish-brown, waved with dusky; top of the head and wings black, speckled with white; tail-coverts red. Found in New Holland.

GRISEA; Grey Manakin. Grey, beneath yellow; hind-head crested; greater wing-coverts red; quill-feathers and tail grey-ash; the front is marked with a yellow spot.

ALBIFRONS; White-faced Manakin. Crest white; body testaceous; back black. There is a variety with a rusty-testaceous body; crest is long and unequal. They are found in divers parts of South America.

ERYTHROCEPHALA; Gold-headed Manakin. Black; head and arm-pits tawny. There is a variety of this species which is black; the head and bracelets red.

AUREOLA; Red and black Manakin. Black; head and breast scarlet; quill-feathers with a white spot on the fore-part. A variety has the head, lower part of the neck, breast, belly, and edges of the wings, orange; the quill-feathers have a white spot within. It inhabits Guinea. The first has a black bill, with legs and claws red; the second has them brown.

CAUDATA; Long-tailed Manakin. Blue; crown scarlet; wings black; two middle tail-feathers long and pointed. It inhabits South America; the sides and neck are tinged with a bright green lustre.

LEUCOCEPHALA; White-headed Manakin. Black, with a white head. It is a native of Surinam, and is the size of a warbler.

LEUCOCILLA. Dusky-black; cap white; a variety is dusky-black; cap white; bracelets red. It is found among the reedy places of South America.

GUTTURALIS; White-throated Manakin. Black, throat white. It is a native of the hottest parts of South America.

SERENA; White-fronted Manakin. Black; front white; rump blue; belly tawny. It is a native of Guiana and Cayenne.

MANACUS; Black-capped Manakin. Black, beneath white; spot on the wings and neck above white. A variety of this species is without the spot on the wings.

MINUTA; Little Manakin. Grey; head black, speckled with white. It inhabits India, and is the size of a wren.

STRIATA; Striped-head Manakin. Beneath yellowish; upper part of the head and nape black, the feathers with a white streak lengthways; the quill-feathers are black, the third very short.

NÆVIA; Spotted Manakin. Brown, beneath tawny; chin and throat black; breast bifid, band on the wings, and

tips of the tail-feathers white. It is about four inches long.

LEUCOTIS; White-eared Manakin. Varied with olive and rufous, beneath rufous; belly grey; crown brown; temples and chin black; on each side the neck is a tuft of long snowy feathers. This is nearly five inches long.

ATRICAPILLA; Black-crowned Manakin. Pale ash-colour, beneath grey-white; bill, crown, greater wing-coverts, and quill-feathers black, the latter edged with grey; the front and cheeks are of a grey-white. It is six inches long, and inhabits Guiana. It avoids the open plains, and haunts the skirts of woods in small flocks. The birds of this species are found in the neighbourhood of ant's nests, from which they are sometimes seen to spring as if stung by the insects, uttering, at the moment, a cry similar to the noise made by cracking a nut.

PAPUENSIS; Papuan Manakin. Greenish-black, beneath whitish; breast with an oblong orange blotch; middle tail-feathers very short. It is a native of New Guinea.

HÆMORRHEA; Crimson-vented Manakin. Deep black, beneath white, vent with a red spot.

NIGRICOLLIS; Black-throated Manakin. Blueish-black; throat and vent black; belly white.

CAPENSIS; Orange-bellied Manakin. Dusky-black, beneath pale orange; edge of the quill-feathers pale, of the wings pale yellowish-orange.

CINEREA; Cinereous Manakin. Cinereous; belly whitish.

MUSICA; Tuneful Manakin. Black, beneath orange; the front and rump yellow; the crown and nape blue; chin and throat black. This is a native of St. Domingo, and is about four inches long. It is extremely shy, and easily eludes the vigilance of those who attempt to catch it; its note is very musical, and forms a complete octave, one note succeeding another. The bill and legs are black.

PIRA, a name given by Aristotle, and other ancient writers, to the *picus varius major*, the great spotted woodpecker, or witwall.

PIPRAH, in *Geography*, a town of Hindoostan, in Vissapour; 13 miles S.E. of Poorunda.—Also, a town of Hindoostan, in Rohilcund; 17 miles S.E. of Budayoon.—Also, a town of Hindoostan, in Oude; 38 miles N.N.E. of Manickpour. N. lat. 26°. E. long. 82° 18'.

PIPRIAC, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Rédon; 10 miles N. of Rédon. The place contains 3150, and the canton 12,161 inhabitants, on a territory of 245 kilometres, in 9 communes.

PIPROW, a town of Hindoostan, in the circle of Bopal; 10 miles S. of Bopaltol.

PIQUE, in *Natural History*, a name given by the Spaniards to an insect of the size of a flea, called by the Indians *tung*. It is common in the East and West Indies, and eats its way into the flesh under the nails, &c.

PIQUE, or *Piquemontvallier*, in *Geography*, the highest mountain among the Pyrenees.

PIQUERIA, in *Botany*, commemorates Andrew Piquerio, a Spanish physician and philosopher, whose works have often been republished at Venice and Amsterdam, and whose merits are highly celebrated by Cavanilles, the author of the name; though without any mention of his botanical pretensions, which would have been, in this case, most to the purpose.—Cavan. Ic. v. 3. 18. Willd. Sp. Pl. v. 3. 1748. Ait. Hort. Kew. v. 4. 501. — Class and order, *Syn-gnesia Polygamia-equalis*. Nat. Ord. *Composita discoidæa*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* simple, prismatic, of four or five converging, concave, keeled, equal scales. *Cor.* compound, discoid.

discoid. Florets few, all fertile, uniform, crowded; tube very short; limb in five spreading segments. *Stam.* Filaments five, very short; anthers united into a cylinder. *Pist.* Germen turbinate, with five angles; style thread-shaped; stigmas divaricated, tumid. *Seeds* solitary, minute, turbinate, with five angles, abrupt at the summit. *Crown* or *down* none. *Receptacle* naked.

Eff. Ch. Receptacle naked. Calyx with four or five equal leaves, and as many florets. Seeds five-angled. Down none.

1. *P. trinervis.* Three-ribbed Piqueria. Cavan. Ic. v. 3. 19. t. 235.—Leaves ovato-lanceolate, ferrated, three-ribbed. Panicle smooth.—Native of Mexico. Seeds were brought from Spain to England in 1798, by the marchioness of Bute. The plant is biennial, flowering in the greenhouse in July and August. The *stems* are herbaceous, four feet high, round, leafy, with opposite branches, panicked and many-flowered. *Leaves* opposite, on short stalks, smooth, like every other part of the plant. *Flowers* very small and numerous, white, on capillary, panicked, terminal stalks. Leaves of the *calyx* four, obovate. *Florets* four.

2. *P. pubescens.* Rough Piqueria.—Leaves dilated, three-lobed, cut. Panicle corymbose, downy.—Native of Peru. A specimen of this, without any name or mark, was found in the herbarium of the younger Linnæus, amongst a number of Peruvian plants. Its *stem* seems rather shrubby, with opposite, round, leafy branches, clothed with fine, short, dense, rusty, rigid down. *Leaves* fan-shaped, acute, nearly smooth, variously cut, and more or less regularly three-lobed, an inch or more in length, on rough stalks about half as long. *Panicle* terminal, corymbose, dense, many-flowered. *Calyx-leaves* five, narrower than in the former. *Florets* about five. In other respects this plant answers to the generic character given of the former by Cavanilles. This genus ranges next to ETHULIA; see that article.

PIQUET. See PICKET.

PIQUETTE, among the *Florists*, a term used for a certain sort of carnations, which have always a white ground, and are spotted, or, as they call it, pounced with scarlet, red, purple, or other colours.

PIQUICA, in *Geography*, a town of Peru, in the diocese of La Plata, on the coast of the Pacific ocean; 85 miles S.W. of Atacames. S. lat. 27°.

PIQUITINGA, in *Ichthyology*, the name of a small American fish, the *Esox Hefseius*, which see. It seldom exceeds two inches in length; its mouth appears very small, but it can at pleasure open it to a great width; its eyes are very large and black, with a silvery iris; it has six fins besides the tail, which is forked; its head is of a silvery white; its back olive-colour, and its belly and sides are covered with silvery scales; the fins are all white, and the side-lines are broad, and very bright and shining. Marcgrave.

PIRA, in *Geography*, a town of Austria; six miles S.S.E. of St. Polten.

PIRA-Aca, in *Ichthyology*, a name by which Marcgrave and some other authors have called the *BALISTES Sinensis* of others.

PIRA-Acangata, the name of a Brazilian fish, resembling the perch in size and shape. It is of a small size, seldom exceeding four or five inches in length; its mouth is small; its tail is forked; and it has on the back only one long fin, which is supported by rigid and prickly spines; this it can depress at pleasure, and sink within a cavity made for it in the back; its scales are of a silvery white. It is a wholesome and well-tasted fish. Marcgrave.

PIRA-Coaba, the name of an American fish of the trutta-

ceous kind, much esteemed for the delicacy of its flavour. It grows to about twelve inches in length; its nose is pointed, and its mouth large, but without teeth; the upper jaw is longer than the other, and hangs over it in form of a cartilaginous prominence; its eyes are very large, and its tail forked; under each of the gill-fins it has a beard made of six white filaments, and is covered all over with silvery scales. Marcgrave.

PIRA-Guiba. See ECHINEIS *Naucrates*.

PIRA-Jurumenbeca, the name of a Brazilian fish, called by many the *bocca molle*. It lives in the muddy bottom of the American seas, and it is a long-bodied not flattened fish; it grows to a vast size, being sometimes caught of nine, and sometimes even of ten or eleven feet long, and two feet and a half thick; it has one long fin on the back, the anterior part of which is thin and pellucid; and has a cavity on the back, into which the creature can depress the fin at pleasure; its tail is not forked; its scales are all of a silvery colour and brightness. It is a very well-tasted fish. Marcgrave.

PIRA-Metara, a name given by Marcgrave and others to a variety of the *MULLUS Surmuletus*.

PIRA-Pebe, the name given by Marcgrave to the *TRIGLA Volitans*; which see.

PIRA-Pixanga, the name of a Brazilian fish of the turdus or wrasse kind, and called by some the *gatvisch*. Its usual length is four or five inches; its mouth is considerably large, and furnished with very small and sharp teeth; its head is small, but its eyes large and prominent; the pupil of a fine turquoise colour, and the iris yellow and red in various shades; the coverings of the gills end in a triangular figure, and are terminated by a short spine or prickle; its scales are very small, and so evenly arranged, and closely laid on the flesh, that it is very smooth to the touch; its tail is not forked, but rounded at the end; its whole body, head, tail, and fins, are of a pale yellow, variegated all over with very beautiful blood-coloured spots; these are round, and of the bigness of hemp-seed on the back and sides, and something larger on the belly; the fins are also spotted in the same manner, and are all marked with an edge of red. It is caught among the rocks, and about the shores, and is a very well-tasted fish. Marcgrave.

PIRÆUS, or PYRÆUS, in *Ancient Geography*, a celebrated and capacious harbour of Athens, about 35 or 40 stadia from the city, but joined to it by walls about five miles in length; that on the north was built by Pericles, and that on the south by Themistocles. This was made the port of Athens by the latter commander, who observing that the ancient port of Phalerum was narrow and inconvenient, constructed the Piræus, which he made the most capacious haven in Greece, and conceiving it inexpedient that the port should be made a part of the city, because, as he knew that sailors are generally dissolute, he was afraid their mixing with the citizens would produce a corruption of manners, he built it at a distance, and connected it with the city by long walls. The site of this port was originally a village of Attica; and in order to render it secure it was encompassed by strong walls. The whole of its circuit was 60 stadia, including the "Munychia," which was a promontory near it, and which being naturally very strong, was rendered still stronger by artificial fortification. On the walls that joined the Piræus with the city, were erected turrets, which were afterwards converted into dwelling-houses for the accommodation of the Athenians, whose large city became in process of time too small for them. It was after the battle of Salamis, which happened in the first year of the 75th olympiad, 480 years B.C., and

by which Athens was elevated to a very high degree of glory, that Themistocles projected the scheme of constructing this new harbour. Accordingly in the last year of the 75th olympiad, 477 years B.C., he explained to the citizens the plan which he had conceived for establishing their power and increasing their wealth. In order the more effectually to secure their concurrence, after stating the advantages that would result to them from the execution of his plan, he requested them to appoint two persons of rank and talents, to whom he might freely communicate the whole of his project. The assembly of the citizens appointed Aristides and Xanthippus, to whom Themistocles imparted, without reserve, his scheme of rendering the Piræus a safe and capacious harbour. To these he demonstrated how easily his scheme might be accomplished, if his intentions were kept secret, and at the same time informed them how dangerous it would be for the Spartans to be apprised of his design. Aristides and Xanthippus assured the people, that the project of Themistocles was of the utmost advantage to the state, and yet that it might be performed with the greatest ease. Nevertheless the people entertained suspicions of some sinister designs, and recommended Themistocles's application to the senate, who having obtained their consent sent ambassadors to Sparta, intimating how fit it would be for the Greeks to have some great port, where a fleet might continue in safety, to watch the designs of the Persians. Having thus prepared the Lacedæmonians not to take offence at their first preparations for enlarging and establishing the harbour of Piræus, Themistocles took such care that every thing was finished, and the place in a posture of defence, before it was well known in Sparta what the Athenians were about.

The entrance of the Piræus is narrow, and formed by two rocky points, one belonging to the promontory of Eetion and the other to that of Alcinous. Within were three docks or stations for shipping, Cantharos, Aphrodisium, and Zea; the first so called from an ancient hero, the second from the goddess Venus, who had there two temples, and the third from bread-corn. In this port were also five porticos, which, joining together, formed one great arcade, called "Macra Stoa," or the grand portico. There were likewise two large markets or fora, one near the long portico, and one near the city. The walls were formed of hewn square stones, and united without cement, merely by lead and iron, which served to hold together the exterior ranges or facings. They were so wide that loaded carts might pass upon it in different directions, and their height was about 40 cubits. These long walls were repaired by Conon, destroyed almost wholly by Lyfander, the Lacedæmonian, and partly reconstructed by Conon, and perfected by Callicrates, during the government of Pericles.

The Piræus, as long as Athens flourished, became the emporium of all Greece. The architect was Hippodamus celebrated for the construction of other buildings.

At the Piræus were a theatre, a temple, or chapel, in which were two statues, one of Jupiter with a sceptre in his hand, and one of Minerva with a pike, and others of Venus, &c. The cavities and windings of the Munychia, both natural and artificial, were filled with houses; and the whole settlement comprehending Phalerum and the ports of the Piræus, with the arsenals, the store-houses, the famous armoury of which Philo was the architect, and the sheds for 300, and afterwards 400, triremes, resembled the city of Rhodes, which had been planned by the same Hippodamus. The ports, on the commencement of the Peloponnesian war, were secured with chains, centinels were stationed, and the Piræus was carefully guarded.

It was with great difficulty that the Piræus was reduced by Sylla, who demolished the walls, and set fire to the armoury and arsenals. In the civil war it was in a defenceless condition. Calenus, lieutenant to Cæsar, seized it, invested Athens, and ravaged the territory. Strabo, who lived under the emperors Augustus and Tiberius, observes, that by many wars the long walls had been destroyed, together with the fortrefs of Munychia, and that the Piræus had been contracted into a small settlement by the ports and the temple of Jupiter the Saviour. This fabric was then adorned on the inside with pictures, the works of illustrious artists, and on the outside with statues. In the second century, besides houses for triremes, the temples of Jupiter and Minerva remained, with their images in brass, and a temple of Venus, a portico and the tomb of Themistocles, whose bones were conveyed hither by his friends from Magnesia.

The port of the Piræus has been named "Porto Leone," from its marble lion, and also "Porto Draco." The lion has been described as a piece of admirable sculpture, ten feet high, and reposing on its hinder parts. Near Athens, in the way to Eleufis, was another, in a couchant posture, probably the companion of the former. Both these were removed to Venice by the famous general Morosini, and placed before the arsenal. At the mouth of the port are two ruined piers. It is frequented by a few vessels, which are, for the most part, small craft. The buildings are a mean custom-house, with a few sheds, and by the shore, on the east side, a warehouse belonging to the French and a Greek monastery dedicated to St. Spiridion. On the opposite side is a rocky ridge, on which are remains of the ancient wall and of a gateway towards Athens. By the water-edge are vestiges of building; and between the custom-house and the city on the right hand of the road are traces of a small theatre on the side of the hill of Munychia.

PIRAGUIRI, in *Geography*, a town of Brasil, in the government of Para, on the Xingi; 85 miles S.W. of Cupura.

PIRANHA, in *Ichthyology*, a name given to the American fish, more commonly known by the name piraya.

PIRANO, in *Geography*, a sea-port town of Istria, situated partly on an eminence, and partly on an isthmus; nine miles S.W. of Capo d'Istria. N. lat. 45° 37'. E. long. 13° 36'.

PIRAQUIBA, or IPIRAQUIBA, in *Ichthyology*, a name originally Brazilian, by which some authors express the remora, or sucking-fish.

PIRATE, PYRATE, *Pirata, Rover*, a person, or vessel, that robs on the high seas, or makes descents on the coasts, without the permission or authority of any prince or state.

The colours usually displayed by pirates are said to be a black field, with a death's head, a battle-axe, and an hour-glass.

By the ancient common law, piracy, if committed by a subject, was held to be a species of treason, and by an alien to be felony only; but now, since the statute of treasons, 25 Edw. III. cap. 2. it is held to be only felony in a subject. Formerly it was only cognizable by the admiralty courts, which proceed by the rules of the civil law; but the statute 28 Hen. VIII. cap. 15. established a new jurisdiction for this purpose, which proceeds according to the course of the common law. The offence of piracy, by common law, consists in committing those acts of robbery and depredation upon the high seas, which, if committed upon land, would have amounted to felony. But,

by

by statute, some other offences are made piracy also; as by 11 & 12 W. III. cap. 7. if any natural born subject commits any act of hostility upon the high seas, against others of his majesty's subjects, under colour of a commission from any foreign power, this, which would be only an act of war in an alien, shall be construed piracy in a subject. And farther, any commander, or other sea-faring person, betraying his trust, and running away with any ship, boat, ordnance, ammunition, or goods, or yielding them up voluntarily to a pirate, or conspiring to do these acts; or any person confining the commander of a vessel, to hinder him from fighting in defence of his ship, or to cause a revolt on board, shall, for each of these offences, be adjudged a pirate, felon, and robber, and shall suffer death, whether he be a principal or accessory. By 8 Geo. I. cap. 24. the trading with known pirates, or furnishing them with stores or ammunition, or fitting out any vessel for that purpose, or in anywise consulting, combining, confederating, or corresponding with them; or the forcibly boarding any merchant vessel, though without seizing or carrying her off, and destroying or throwing any of the goods overboard, shall be deemed piracy; and all accessories to piracy are declared to be principal pirates and felons, without benefit of clergy. Commanders or seamen wounded, and the widows of such as are slain, in any piratical engagement, shall be entitled to a bounty, to be divided among them, not exceeding one-fiftieth part of the value of the cargo on board; and such wounded seamen shall be entitled to the pension of Greenwich hospital. And if the commander shall behave cowardly, by not defending the ship, if she carries guns or arms, or shall discharge the mariners for fighting, so that the ship falls into the hands of pirates, such commander shall forfeit all his wages, and suffer six months' imprisonment.

In different parts pirates are differently denominated; as in the West Indies, *buccaneers*, *free-booters*, &c. In the Mediterranean, *corsairs*, &c.

Alexander, reproaching a pirate with his condition, was answered, "If I am a pirate, it is because I have only a single vessel; had I a fleet, I should be a mighty conqueror."

PIRATE was also anciently used for the person to whose care the mole, or pier of a haven, which, in Latin, was called *pira*, was entrusted.

PIRATE was sometimes too, according to Spelman, used for a sea-captain, or soldier. Afler, in the life of king Alfred, tells us, "justit naves longas fabricari, impositisque piratis in illis vias maris custodiendas commisit."

PIRATIAPIA, in *Ichthyology*, the name of a Brazilian fish, approaching to the nature of the turdus or wrasse. Its body is oblong, not flattened, and very thick; it is a large fish, and sometimes grows even to fifty pounds weight. It is a very delicate and valuable fish. Marcgrave.

PIRATIA-PUA, the name of an American sea-fish, which grows to a very large size, and, while young, is eaten and accounted a delicacy; but when full grown, is too coarse, rank, and strong: it has six fins besides the tail, which is made of a very large fin, of a somewhat square figure, and is not at all forked: it is all over of a dusky orange colour, but more obscurely so on the back than elsewhere; and its sides are variegated with grey spots, so disposed as to represent a sort of net-work. Pifo.

PIRAUGY, in *Geography*, a river of Brazil, S.S.E. of Rio Grande and Point Negro.

PIRAUMBU, in *Ichthyology*, the name of a Brazilian fish, somewhat approaching to the nature of the turdus, and called by the Portuguese *chayquarona*. It is of the figure of the carp, and its usual length is six or seven inches, and its breadth in the broadest part about three inches, but gra-

dually diminishing to the tail. It is caught among the rocks, and near shores, and is a well tasted fish. Marcgrave.

PIRAY, in *Geography*, a river which runs into the Paraguay.

PIRAYA, a town of Paraguay; 20 miles S.E. of Assumption.

PIRAYA, in *Ichthyology*, the name of a fish caught in the American rivers. There are two kinds of it: the one growing to a foot long, and very broad in proportion; this loves the muddy bottoms of rivers; the other is much of the same size, but has two fins on its back, whereas the other has but one; this loves the sandy bottoms of rivers. There is also a smaller species of this: all three are eatable fish.

PIRAZZETA, in *Geography*, a town of Naples, in Basilicata; 14 miles N.E. of Turfi.

PIRDE, a river of Prussia, which runs into the Memel, four miles W. of Tiltit.

PIRETIBBI, a lake of Canada, 240 miles N. of Quebec. N. lat. 51°. E. long. 69° 40'.

PIRGIA, a town of Asiatic Turkey, in Caramania; 112 miles S.W. of Cogni.

PIRGO, a town of Albania, at the mouth of the river Polonia; 20 miles N. of Valona.

PIRHALA, a town of Hindoostan, in Lahore; 108 miles N.W. of Lahore. N. lat. 32° 36'. E. long. 71° 56'.

PIRI, a province of Africa, in the N. part of the kingdom of Loango.

PIRIATIN, a town of Russia, in the government of Kiev; 68 miles E.S.E. of Kiev. N. lat. 51° 18'. E. long. 32° 42'.

PIRIG, a town on the S. coast of the island of Luçon. N. lat. 13° 39'. E. long. 122° 24'.

PIRIGARA, in *Botany*, Aubl. Guian. t. 192, 193. See GUSTAVIA.

PIRIN'S ISLAND, in *Geography*, an island near the coast of Africa, in the mouth of the river Olibato; eastward of cape Lopez Gonfalvo, about five miles in circumference.

PIRIOUTI, a town of Thibet; 60 miles E. of Panc-tou.

PIRIPEA, in *Botany*, an unexplained, probably barbarous, name. Aubl. Guian. v. 2. 627. Juss. 100.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personate*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, its orifice in five unequal acute segments. *Cor.* of one petal, salver-shaped; tube cylindrical, curved, twice the length of the calyx; limb spreading, in five deep, unequal, obovate segments; mouth closed with oblong glands. *Stam.* Filaments four, thread-shaped, inserted into the middle of the tube, two of them longer than the rest, all enclosed within the tube; anthers erect, oblong, of two cells. *Pist.* Germen superior, oblong, quadrangular; style short; stigma swelling, acute. *Peric.* Capsule oblong, compressed, of two cells, and two valves. *Seeds* numerous, minute, inserted into the partition.

Eff. Ch. Calyx tubular, with five unequal teeth. Corolla salver-shaped, curved; limb in five obovate, unequal segments; mouth closed with glands. Capsule of two cells. *Seeds* numerous, minute.

1. *P. palustris*. Aubl. Guian. t. 253.—Native of the meadows of Courou in Guiana, flowering and ripening fruit in September.—*Root* small, fibrous, apparently annual. *Stem* a foot high, erect, slender, leafy, striated, somewhat branched. *Leaves* scattered, sessile, linear, acute, very narrow, channelled, finely toothed, smooth. *Flowers* in loose, terminal, simple spikes. *Brañtas* three, fringed, at the base

of each flower. *Flowers* hardly an inch long, purplish; the glands at the mouth white. A pretty delicate plant, thought by Jussieu to constitute a distinct genus, akin to *Erinus*, *Buchnera*, *Manulea*, *Burisia*, &c. We have seen no specimen. Swartz cites it as a synonym to his *Buchnera elongata*. See BUCHNERA.

PIRIQUETA, Aubl. Guian. t. 117. See TURNERA.

PIRIT, in *Ornithology*, a name given by the people of the Philippine islands to a peculiar species of sparrow, which is very common with them. It is much smaller than our common sparrow, and feeds only on the seeds of the canary-grass, which is very commonly wild there.

PIRITU, in *Geography*, a small island in the Caribbean sea, near the coast of South America. N. lat. 10° 10'. W. long. 65° 26'.

PIRITZ, a town of Hinder Pomerania, which was the first town of the country that embraced Christianity, and also the doctrines of Luther; 32 miles N. of Custrin. N. lat. 53° 13'. E. long. 15° 4'.

PIRLIPO, a town of European Turkey, in Macedonia; 20 miles N.N.E. of Toli.

PIRMAKAN, a town of Bengal; 15 miles S.W. of Purneah.

PIRMASENS, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the district of Deux-Ponts; 12 miles S.E. of Deux-Ponts. The place contains 3205, and the canton 8147 inhabitants, in 21 communes.

PIRNA, a town of Saxony, in the margraviate of Meissen, advantageously situated on the Elbe for commerce; 11 miles S.E. of Dresden. N. lat. 50° 58'. E. long. 13° 56'.

PIRNITZ, or BOTNITZ, a town of Moravia, in the circle of Iglau; 10 miles S.E. of Iglau.

PIROGUIS, a name given by the Americans to their war-boats, which were a sort of canoes, so large as to carry 40 or 50 men.

PIROM, or TUICCE, an island in the Red sea. N. lat. 15°. E. long. 42° 40'.

PIROMALLI, PAUL, in *Biography*, an Italian Dominican, who flourished in the 16th century, and whose labours have greatly contributed towards the promotion of Oriental literature, was a native of Calabria. He was sent as a missionary into the East, and was said to have converted great numbers of the Eutychians to the Catholic faith. From Armenia he passed into Georgia and Persia, and upon his return into Italy by sea, he was taken and carried captive to Tunis. Being ransomed, he went to Rome, where he gave an account of his mission, and received marks of favour from pope Urban VIII. By this pontiff he was sent into Poland, with the character of papal nuncio, and is said to have been very successful in restoring union and harmony among the sects in that country. The same pope employed him in revising the Armenian version of the bible; and afterwards sent him a second time into the East, where, in 1655, he was promoted to the bishopric of Nakhivan, in Armenia. Over this see he presided nine years, and then returned to Italy, where he was nominated bishop of Bisignano, in Calabria. Here he died in 1667. He was author of a "Latin and Persian Dictionary;" "An Armenian and Latin Dictionary;" "A Grammar of the Armenian Tongue;" and some treatises in controversial divinity.

PIRON, ALEXIS, a poet and man of wit, was born at Dijon in 1689. He passed the first twenty-five years of his life in obscurity, remote from decent company, and devoted very much to low pleasures. A licentious ode, of which

he was the author, obliged him to quit Paris, where, for some years, he had supported himself by the mechanical labours of his pen as a copying clerk. His first literary efforts were as a writer for the comic opera, in which inferior station he displayed talents that recommended him to the directors of the Theatre François. His first effort, entitled "Les Fils ingrats," afterwards changed into "L'Ecole des Pères," was not at all successful. He next tried his powers in tragedy, and produced his "Callisthenes," and his "Cortes," neither of which has kept a place on the stage, though containing parts strongly written. His "Gustave" was more successful, though critics thought it too much overcharged with business; at length, in 1738, he presented his comedy of "La Metromanie," which raised him to the height of reputation. He also wrote "Les Courfes de Tempe," an ingenious pastoral; several odes, poems, tales, and epigrams. In this last kind of composition he was particularly happy, as might be expected, considering that he was the most famous for repartees and bon mots of any of the Parisian wits. Of these several are given in the General Biography. He frequently made caustic remarks upon the French Academy, and afterwards exerted himself to obtain admission into it, but was excluded by means of the abbé d'Olivet, who revived the memory of his juvenile ode, for which officiousness he was recompensed by a severe epigram. Piron never forgave the Academy for their rejection of him, and composed the following epitaph:

" Ci git Piron, qui ne fut rien,
Pas même academicien."

He died at the advanced age of 83, having been long regarded as a very estimable character. His works were published collectively in seven volumes.

PIROS, in *Geography*, a jurisdiction of Peru, on the sides of the Maragnon; 160 miles N.N.E. of Lima.

PIROT, a town of European Turkey, in Bulgaria; 40 miles N.W. of Sophia.

PIROTE, a town of Hindoostan, in Malwa; 21 miles N.W. of Chanderee.

PIROUETTE, or PYROUET, in the *Manege*, a turn or circumvolution which a horse makes, without changing his ground; his haunches remaining firm in the centre, and his shoulders furnishing and describing the circle. In this action the inner hind leg must not be lifted from the ground, but turned round in the same place, like a pivot: while the other three legs and the body of the horse turn and wheel round it at the same time.

The word is French, and literally signifies a whirligig.

Pirouettes are either of *one tread*, or *pisle*, or of *two*. The first is an entire short turn, which the horse makes upon one tread, and, almost, in one time; in such a manner as that his head comes to the place where his tail was, without putting out his haunches. In the pirouette of *two treads*, or *pisles*, he takes a small compass of ground, almost his length, and marks both with the fore part and the hind.

PIRRAWARTH, in *Geography*, a town of Austria; 14 miles N.N.E. of Vienna.

PIRUZABAD, a town of Persia, in Mecran; 30 miles S.S.E. of Kieh.

PISA, in *Ancient Geography*, a town of the Peloponnesus, in that part of the Elide called Triphylia, N. of Olympia, and, according to Herodotus, 1485 stadia distant from Athens. It was situated on the right of the river Alpheus, and even after its destruction the inhabitants of this district bore the name of Pisantins; and here was also a fountain called "Pifa." The inhabitants of this town, founded, as it is said, by one of the grandsons of Eolus, were for a long time

PISA.

time the most powerful people of the Elide. Pausanias says, that vines covered the site of Pisa.

PISA, in *Geography*, a city of Etruria, and capital of a territory, stands in a fertile plain, bounded by the neighbouring Apennines on the N., and on the S. open to the Tyrrhenian sea. If we may rely on the authority of Strabo, we may trace the origin of Pisa to the period that followed the Trojan war, and thus connect its history with the fate of the Grecian chiefs, and particularly with the wanderings of the venerable Nestor. At all events the

“Alphæ ab origine Pifæ
Urbs Etrufca folo,”

enjoys the double glory of being one of the most ancient cities of Etruria, and of deriving its name and its origin from the Olympic Pifa, on the banks of the Alpheus. Although this city was always considerable, as forming one of the Etruscan tribes, or afterwards honoured with a Roman colony, A. U. C. 474; yet it did not arrive at the zenith of its fame till the records of ancient times were closed, and the genius of Rome and liberty seemed for ever buried under the ruins and barbarism of the middle ages. At that period, apparently so unpropitious, the flame burst forth, and again kindled the slumbering spirit of Italian freedom. Pisa was not the last that roused itself to activity; it asserted its independence at an early period, and in the 10th century blazed forth in all the glory of a mighty and victorious republic. Its numerous fleets rode triumphant on the Mediterranean; and Corsica and Sardinia, the Saracens on the coast of Africa, and the infidel sovereign of Carthage, bowed beneath its power. Captive kings appeared before its senate; the Franks in Palestine and in Egypt owed their safety to its prowess, and Naples and Palermo saw its flags unfurled on their towers. Pontiffs and emperors courted its alliance, and acknowledged its effective services, and the glory of Pisa, twenty centuries after its foundation, eclipsed the fame of its Grecian parent, and indeed rivalled the achievements of Sparta herself, and of all the cities of Peloponnesus united. During this era of glory, commerce, as well as conquest, introduced opulence and splendour into the city; its walls were extended and strengthened; its streets widened and adorned with palaces, and its churches rebuilt in a style of magnificence, that even now astonishes the traveller, and attests the former fortunes of Pisa. A population of 150,000 inhabitants filled its vast precincts with life and animation, and spread fertility and riches over its whole territory. Such was its state during the 11th, 12th, and great part of the 13th centuries, after which the usurpation of domestic tyrants first, and next the victories of the Genoese, broke the spirit of its citizens. Then the treachery of its princes, with the interference and deceitful politics of France, undermined its freedom, and at length the intrigues of the Medici completed its ruin, and enslaved it to its rival Florence, about the year 1228. While the neighbouring Lucca, not so glorious but more fortunate than Pisa, still retains its opulence and its population. The latter, enslaved and impoverished, can count only 15,000 inhabitants within the whole circumference of her walls:—a number which, in the days of her prosperity, would have been insufficient to man one-half of her galleys, or guard her ramparts during the watches of the night.

Pisa covers an inclosure of near seven miles in circumference; the river divides it into two, nearly equal, parts; the quays on both sides are wide, lined with edifices in general stately and handsome, and united by three bridges, the middle one of which is of marble. The streets are wide, particularly well paved with raised flags for foot passengers, and the

houses are lofty, and of good appearance. Here are several palaces, not deficient either in style or magnificence. Among its churches, there is a singular edifice on the banks of the Arno, called “Santa Maria della Spina,” supposed to have been built A. D. 1230, and repaired A. D. 1300. so called from part of our Saviour’s crown of thorns said to be preserved there, square, low, and of a grotesque and whimsical, rather than beautiful appearance. It is faced with black and white marble. This building is a specimen of that species of architecture which the Italians call “Gotico Morefco,” introduced into Italy in the 11th century, and, as its name seems to import, probably borrowed from the East by the merchants of the commercial republics. We shall here observe, that there are in Italy two species of Gothic, the “Gotico Morefco,” and the “Gotico Tedefco;” the former may have been imported from the East; the latter seems, as its name implies, to have been borrowed from the Germans. It is thought to be an improvement of the former.

The finest group of buildings of the above description, perhaps, in the world, is that which Pisa presents to the contemplation of the traveller in her cathedral, and its attendant edifices, the baptistry, the belfry, and the cemetery. The cathedral is the grandest, as it is the most ancient; it was begun in the middle, and finished before the end of the 11th century. We shall restrict ourselves to a description of the campanile or belfry, which is the celebrated leaning tower of Pisa. It stands at the end of the cathedral, opposite to the baptistry, and consists of eight stories, formed of arches supported by pillars, and divided by cornices. The elevation of the whole is about 180 feet. The form and proportion of this tower are graceful, and its materials, being of the finest marble, add to its beauty; but its grand distinction, which alone gives it so much celebrity, is a defect which disparages the work, though it may enhance the skill of the architect, and by its novelty forcibly arrest the attention; we allude to its inclination, which exceeds fourteen feet from the perpendicular. Many ascribe this architectural phenomenon to design, and this is now the generally received opinion. The quantity of marble contained in the four immense edifices above-mentioned, and the number of pillars employed in their decoration, are truly astonishing. It does not appear that they belonged to any edifices in this city or its vicinity. They may have been imported by the Pisan galleys in their triumphant returns from Majorca, Sardinia, Corsica, Carthage, Sicily, and Naples, and may perhaps be considered rather as monuments of the victories of this once powerful republic, than as remains of its municipal magnificence under the Romans. Although the style of this group of edifices has been called Gothic, it is, in fact, a composite style formed of Roman orders, corrupted and intermingled with Saracenic decorations. Pisa has several other churches, besides the cathedral, that are magnificent and much admired. Its baths are about four miles from the city, and spring up at the foot of “Monte St. Giuliano;” they were frequented anciently, perhaps, more than at present. The remains of an ancient aqueduct may be seen at a little distance, but they are eclipsed by a modern one of 1000 arches, erected originally in order to supply Pisa, and now carried on to Leghorn. The university of Pisa was one of the nurseries of reviving literature, and under the auspices of republican liberty, rivalled the most celebrated academies in Italy, when they all teemed with genius and science. Upon the subjugation of Pisa to the Florentines, it sunk into insignificance; but it was afterwards restored by Lorenzo de Medici: it again declined, and was restored by the

the grand duke Cosmo I. Since that period it has continued the feat of many eminent professors, though it has never regained the number of its students, or all its ancient celebrity. It has more than forty public professors, who are resident, and men of high reputation in their respective departments. It is well furnished with all the apparatus of an academy;—colleges, libraries, an observatory, with all the astronomical instruments in great perfection, and an extensive, well-ordered botanical garden. Pisa is, indeed, the seat of Tuscan education, and frequented by the subjects of the Florentine government.

Pisa is only four miles from the sea; its port was anciently at the mouth of the Arno, and a place of some fame and resort. It thus gave its name to a bay which extended from the promontory of Populonia, now Piombino, to that of Luna or Venus, Porto de Venere, and was called the "Sinus Pisanus." According to Strabo, the Aufer flowed into the Arno at Pisa, though it now falls into the sea at the distance of at least ten miles from it. Pisa and Leghorn are connected by a canal, 16 Italian miles in length; 42 miles W. of Florence. N. lat. 43° 42'. E. long. 10° 15'.

PISAN, IKAN, in *Ichthyology*. See CENTRISCUS *Scutatus*.

PISANG, in *Geography*. See PULO Pifang.

PISANIA, called also *Kuttijar Factory*, a town of Africa, in the kingdom of Yani, situated on the banks of the river Gambia, about 200 miles from its mouth, where the English have established a factory. N. lat. 13° 35'. W. long. 13° 28'. This was the outlet of Mr. Park's journey for discoveries in Africa, under the direction of the African Association, and the residence of Dr. Laidley, who deserves mention on account of his kind and hospitable treatment of the adventurous traveller, whom he received into his house, and attended for many weeks during a serious illness; and whom he furnished with every necessary for his journey, when he was disappointed of the goods requisite for his expenses, taking bills upon the Association for the amount. From Pisania, Mr. Park proceeded eastward to Medina, the capital of Wolli, and thence to the E.N.E. through the countries of Bondou, Kajaaga, and Kasson, the two latter of which are separated by the river Senegal. In his way, he took observations of latitude at Kolor (N. lat. 13° 49'), Koorkoorany (13° 53'), and Joag (14° 25'). W. long. 9° 37'), on this side the river. From Joag he proceeded to Kooniakarry (14° 34'), and from Kooniakarry by Kanjee (14° 10'), both in the country of Kasson, and Fessurah (14° 5') in Kaarta, to Jarra (15° 5', long. 7° 13'), in the country of Ludamar. Here he was plundered of his sextant, which accident of course put an end to his observations of latitude; and thus, unfortunately, left the remaining half (very nearly) of his geography in a state of uncertainty as to parallel. Mr. Park pursued his journey from Jarra by Wassiboo (14° 49'), and 95 geographical miles E. of Jarra, Diggani (lat. 14° 17', and 266.1 geographical miles E. of Jarra), to Sego, the capital town of Bambara (lat. 14° 10' 30", and long. 2° 26' W. of Greenwich.) Having at length reached the banks of the long sought for river Niger (or Joliba), near which the city of Tombuctoo stands, Mr. Park proceeded along it several days' journey towards this city, on a course, which places Silla, the extreme point of his expedition, in lat. 14° 48', and long. by reckoning corrected 1° 24' W. of Greenwich. Here then terminates his journey eastward, at a point somewhat more than 16° E. of Cape Verd, and precisely in the same parallel. Jinné, a large town, lies two short journeys below Silla and Tombuctoo, twelve still lower down; and it would appear that all the

journeys were conceived to be short, as Mr. Park allows only 200 geographical miles for the aggregate of the fourteen journeys of the caravan. (See *TOMBUCTOO*.) For other particulars we refer to Proceedings of the Association for promoting the Discovery of the Interior Parts of Africa; containing an abstract of Mr. Park's Account of his Travels and Discoveries, abridged from his own Minutes, by Bryan Edwards, esq.—Also, *Geographical Illustrations of Mr. Park's journey, and of North Africa at large*, by Major Rennell, 1798.

PISAQUA, a town of Peru, in the diocese of Arequipa, on the coast; 40 miles S. of Arica.

PISATELLO, a river of Italy, which rises in the department of the Rubicon or Rouagna, and being joined by two other streams, runs into the Adriatic, between Rimini and Cervia. See RUBICON.

PISCA PIGNATARA, a town of Naples, in the county of Molise; 15 miles N.W. of Molise.

PISCADORE ISLANDS, a cluster of islands in the North Pacific ocean. N. lat. 11° to 11° 20'. W. long. 192° 30' to 193°.

PISCADORES, or FISHERS, two huge rocks on the coast of Peru, near the broken gap between Attico and Ocona. S. lat. 16° 48'.

PISCADORES. See PONG-HU.

PISCADORES, six rocks near the coast of Peru; 5 leagues N.N.W. of Callao. S. lat. 12° 14'.

PISCARY, PISCARA, in our *Ancient Statutes*, the liberty of fishing in another man's waters.

This differs from a free fishery, which is an exclusive right: in this last the man has a property in the fish before they are caught; in a common of piscary, not till afterwards.

PISCATAQUA, or PASCATAQUA, in *Geography*, the only large river whose course is in New Hampshire, rising in a pond in the N.E. corner of the town of Wakefield, and pursuing a general S.S.E. course of about 40 miles to the sea. It divides New Hampshire from York county, Maine, and is called Salmon Fall river from its head to the lower Falls at Berwick, where it assumes the name of Newichawannock, which it bears till it meets with Cocheco river, which comes from Dover, when both run together in one channel to Hilton's Point, where the western branch meets it; from this junction to the sea the river is so rapid, that it never freezes. At the lower falls in the several branches of the river are landing places, whence lumber and other country produce are transported, and vessels and boats from below discharge their lading. This river, by its form, and the situation of its branches, is very favourable to the purposes of navigation and commerce. A light-house stands at the entrance of Piscataqua harbour, in N. lat. 43° 41', and long. 70° 41'.

PISCATAWAY, a township of New Jersey, in Middlesex county, on Rariton river, six miles from its mouth. In 1810 it had 2475 inhabitants; three miles and a half N.E. of New Brunswick.—Also, a small post-town of Prince George's county, Maryland, on the creek of its name which runs W. into Patowmac river, opposite to mount Vernon in Virginia, and 14 miles S. of Washington. The town is 16 miles S.W. of Upper Marlborough.

PISCES, in *Astronomy*, the twelfth sign, or constellation of the zodiac.

The stars in Pisces, in Ptolemy's Catalogue, are 38; in Tycho's, 36; in Hevelius's, 39; in the Britannic Catalogue, 113. See CONSTELLATION.

PISCES, in *Natural History*, is the name of the fourth of the classes into which Linnæus has distributed the animal kingdom;

PISCES.

kingdom; and the science treating of the orders, genera, species, &c. of this class, is denominated *Ichthyology*. From this word we referred to the present article, meaning to give a very brief sketch of the science, so much having been already said of the structure, the anatomy, and functions of fishes under the article FISH, to which we refer our readers for abundant of interesting information on the subject.

The element in which fishes live prevents us from following their motions with exactness, from coming to any very accurate knowledge of their habits and instincts, and from noting with fidelity their specific differences. Their colours, which sometimes are very brilliant, frequently vary, with the accidental circumstances of age, sex, climate, season, &c., and often vanish by exposure to air, or with the principle of life. Hence the natural history of fishes has ever been involved in greater obscurity than that of land animals, which are more readily subjected to the investigation of the learned and curious. Hence the earlier writers on this subject, as Aristotle, Pliny, and Ælian, have mingled as much fable as truth in their accounts, so that they afford few facts that can be depended upon in a scientific point of view. The classical reader may, however, derive entertainment and some instruction from a perusal of their books, with the comments of the learned upon them. Athenæus also discourses of fishes in the seventh book of his *Deipnosophistæ*, as does Oppian in his *Halicuticon*, a Greek poet, who flourished under the reign of Caracalla. (See *OPPIAN*.) Ausonius, a native of Bourdeaux, in the fourth century, in his poem on the river Moselle, has not passed its inhabitants unnoticed. In the dark and middle ages, no writer of note appeared in this department of natural history. The first person who laid the foundation of ichthyological arrangement was Pierre Belon, a French physician, who flourished in the sixteenth century, and who is known by his travels in Judea, Greece, and Arabia, as well as by his writings in natural history. Some of his divisions are deduced from natural resemblances, but others are more fanciful. Belon was an industrious and acute observer, and will be deservedly held in estimation when it is considered how few the resources were of which he could avail himself. (See *BELON*.) His history of fishes appeared in 1551; that of his countryman Rondelet was published three years afterwards, and exhibited more accurate descriptions, and better executed figures, with many excellent remarks, the result of his own observation. He had the merit of exciting a general taste for the study of ichthyology, and was rapidly followed by Salviani, Boffueti, Conrad Gefner, Pifon, &c.

Aldrovandus, in 1605, who published a large compilation of Natural History, distributed the fishes according to the nature of their residence: thus he treats, in his *first* book, of those that frequent rocks; in the *second*, of those that live close to the shores, &c. The labours of this naturalist, and of others in the same department, were eclipsed by those of Willoughby, whose work, entitled "*De Historia Piscium*," was printed at Oxford in 1686, and unfolded many new and accurate notions relative to the anatomy and physiology of fishes. His arrangement may be considered as an improved modification of that of Belon. Ray published, in 1707, his "*Synopsis Methodica Piscium*," which may be regarded as an abridged and corrected view of Willoughby's larger work, and as indicating, rather than fixing, a series of genera. This valuable descriptive catalogue continued to be appealed to as a standard, till Artedi and Linnæus effected important changes in the science of ichthyology. The former of these died before he could mature the plan on which he was engaged, and Linnæus, his friend and coadjutor, put the finish-

ing hand to his papers, and then published them in two vols. 8vo. under the titles of "*Bibliotheca Ichthyologica*," and "*Philosophia Ichthyologica*," which in 1792 were republished in four vols. On this account we may ascribe to Artedi the merit of having first traced the outlines of that classification of fishes which is now generally received among the studious and learned in Europe. He first instituted the orders and genera, and defined the characters on which these divisions are founded. Independently of the cetaceous tribes, which are now classed with the Mammalia, the method of Artedi consisted of four great divisions, *viz.* 1. The *Malacopterygian*, which denoted those fishes which have soft fins, or fins with bony rays, but without spines: this order included 21 genera. 2. The *Acanthopterygian*, or those with spiny fins, containing 16 genera. 3. The *Branchiostegous*, which corresponds to the *amphibia nantes* of Linnæus, which want the operculum, or branchiostegous membrane; and 4. The *Chondropterygian*, which answers to that part of the *amphibia nantes*, which have not true bones, but only cartilages, and the rays of whose fins scarcely differ from a membrane. In the first edition of the System of Nature, Linnæus wholly adopted the method of Artedi, but more reflection led him to those changes which he afterwards adopted, and which he matured into that luminous and beautiful system, of which we have so greatly availed ourselves in the course of this work.

We may, before we mention the system of Linnæus as it now stands, observe, that other persons of great learning, of deep research, and accurate observation, have proposed different modes of arrangement, but when they have gone contrary to the method of the Swedish naturalist they have usually been deficient in simplicity. Thus Klein, who attempted to rival him, distributed fishes into three sections, according as they had lungs, and visible or invisible gills; but his sub-divisions were so numerous and complex, that his scheme has never been adopted. That of Gronovius, which lasted but a few years, was founded principally on the presence or absence, and the number or the nature of the fins. The first class includes all the cetaceous animals, and the second all the fishes properly so called. The chondropterygian, and the osseous or bony, form two great divisions, and the osseous are sub-divided into branchiostegous and branchial. These last are grouped according to the Linnæan rules, but in the formation of the genera, the number of the dorsal fins is admitted as a character. Brunnich laboured, but unsuccessfully, to combine the original method of Artedi with the improved one of Linnæus. Scopoli struck out a new path, and assumed the position of the *Anus* as the basis of his three primary divisions; and his secondary characters sometimes coincided with those of Gronovius, and sometimes with those of Linnæus; while his third series of distinctions was drawn sometimes from the form of the body, and sometimes from the teeth. Another ichthyologist, Gouan, the professor of botany at Montpellier, preserved the Linnæan genera, but formed his greater divisions from the union of those of Linnæus and Artedi. His chief sections are of fishes with *complete*, and of those with *incomplete* gills. The first of these is divided into two others, *viz.* *Acanthopterygian*, and *Malacopterygian*, in each of which are arranged the apodal, the jugular, and abdominal species; and a similar process is followed in the second section, which includes the *Branchiostegous* and the *Chondropterygian*. All the authors to which we have thus briefly referred, excepting Belon, Rondelet, and Gronovius, published their works without any regular series of plates illustrative of their descriptions; but there are others who have embellished their volumes with very valuable figures, among whom is Seba,

in his collection of subjects belonging to natural history; Catesby, in his Natural History of Carolina; Broussonet, in his Ichthyologia; and Bloch, in his Natural History of Fishes, first published at Berlin in German, and afterwards reprinted in French in 1785, forming a part of the Histoire Naturelle de Buffon. The original work of Bloch included about 600 species of fishes, which are generally described with accuracy, and figured according to the best means which he possessed, of the natural size, and beautifully coloured. In the historical departments he dwells with minuteness on those that afford food for man, or which suggest facts worthy of remark. He followed the Linnæan method, and made considerable additions to the number of genera. La Cépède, the friend and continuator of Buffon, has executed an elaborate and extensive work on the natural history of fishes. This class of animals he divides into two secondary classes, viz. the cartilaginous and the osseous; each of these consists of four divisions, taken from the combinations of the presence or absence of the operculum, and of the branchial membrane; thus, according to this system, the first division of the cartilaginous includes those fishes which have neither operculum nor branchial membrane; the second, which have no operculum, but a membrane; the third, which have an operculum, but no membrane; and the fourth, those that have both. The same characters, stated in an inverse order, determine the divisions of the osseous species. Each of these divisions is again distributed into the Linnæan orders, and these in their turn are divided into the Linnæan genera, though the latter do not always correspond exactly to those of the Swedish naturalist.

According to the Linnæan system of ichthyology, as it is now arranged, and which is generally followed in the New Cyclopædia; the fins of fishes are named from their situation on the animal, viz. the dorsal or back-fin; the pectoral or breast-fins; the ventral or belly-fins; the anal or vent-fin; and the caudal or tail-fin. The ventral-fins are considered by Linnæus as analogous to feet in quadrupeds, and it is from the situation, presence, or absence of these fins, that he instituted the first four orders of fishes; the other two orders were formed from the nature of their gills: thus,

Orders.

- I. Apodes are fishes entirely destitute of ventral fins.
- II. Jugulares are fishes that have the ventral fins before the pectoral.
- III. Thoracici are fishes that have the ventral fins under the pectoral.
- IV. Abdominales are fishes that have the ventral behind the pectoral.
- V. Branchiostegous are fishes whose gills are destitute of bony rays.
- VI. Chondropterygious are fishes whose gills are cartilaginous.

The generic character is taken from the shape of the body, the covering, structure, figure, and parts of the head, but principally from the branchiostegous membrane (see FISH); and the specific character is taken from the cirri, jaws, fins, spines, lateral line, digitated appendages, tail, and colour.

In more modern systems of ichthyology, the last two orders in the Linnæan system are included in the order Pisces cartilaginei, or cartilaginous fishes, which differ from others in having a cartilaginous instead of a bony skeleton. (See CARTILAGINOUS FISHES.) This method is adopted in Dr. Shaw's very instructive and entertaining work, entitled "General Zoology," to which our readers are referred.

Mr. Pennant, "in his British Zoology," describes the fishes under the three great divisions of *cetaceous*, *cartilaginous*, and

bony. The latter, which is by far the most numerous, he sub-divides into four sections, viz. the *apodal*, *thoracic*, *jugal*, and *abdominal*.

PISCH, in *Geography*, a river of Poland, which runs into the Narew, near Pultusk, in the duchy of Warsaw.

PISCHMA, a river of Russia, which runs into the Tura, near Tiumen.

PISCHSTEIN, a town of Prussia, in Ermeland; 11 miles S.E. of Heilsberg.

PISCIDIA, in *Botany*, from *piscis*, a fish, and *caedo*, to slay or destroy, because it is used for the purpose of intoxicating fish, so that they are easily caught.—Linn. Gen. 367. Schreb. 486. Willd. Sp. Pl. v. 3. 909. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 4. 253. Juss. 358. Lamarck Illustr. t. 605.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth inferior; of one leaf, bell-shaped, with five teeth; the two uppermost nearest each other. Cor. papilionaceous. Standard ascending, emarginate. Wings equal to it in length. Keel crescent-shaped, ascending. Stam. Filaments ten, united into a sheath split along its upper side; anthers oblong, incumbent. Pist. Germen superior, stalked, compressed, linear; style thread-shaped, ascending; stigma acute. Peric. Legume stalked, linear, with four longitudinal membranous angles, of one cell, separated into several divisions by a kind of plaits. Seeds few, nearly cylindrical.

Ess. Ch. Stamens all connected. Stigma acute. Legume with four wings.

1. *P. Erythrina*. Jamaica Dog-wood, or Fish-bean. Linn. Sp. Pl. 993. Willd. n. 1. Ait. n. 1. Jacq. Amer. 209. Swartz Obs. 276. (*Piscipula Erythrina*; Leoffl. It. 275. *Ichthyomethia* n. 1; Browne Jam. 296. *Pseudocacia*, filiquis alatis; Plum. Ic. 229. t. 233. f. 2. Coral arbor, &c.; Sloane Jam. v. 2. t. 176.)—Leaves pinnate; leaflets ovate.—Native of the West Indies. By road sides in Jamaica, on dry chalky hills. The bruised leaves and branches being thrown into water where there are fish, the latter become so intoxicated as to be easily taken by the hand, as they float on the surface. Many other West Indian plants possess the same property. *Jacquin*. (See PHLOMIS.) A large ungraceful tree, twenty-five feet high, easily recognised at a distance by its irregular and singular form of growth. Leaves alternate, deciduous, pinnate with an odd leaflet; large, downy, the leaflets ovate, or rather obovate, entire. Clusters numerous, erect, many-flowered, lateral or terminal. Flowers white, the size of a common pease-blossom. They come out in March and April, before the leaves. Legume four or five inches long, with very broad wings.—*P. carthagenensis*, Jacq. Amer. 210. Linn. Sp. Pl. 993. Willd. n. 2, for which Pluk. Phyt. t. 214. f. 4. is quoted, appears evidently to be merely a variety, with more obovate leaves. *Jacquin* cites for this the above figure of Plumier, which other authors make *P. Erythrina*.

2. *P. punicea*. Scarlet Fish-bean. Cavan. Ic. v. 4. 8. t. 316. Willd. n. 3.—Leaves abruptly pinnate; leaflets obtuse.—Native of South America. It has borne flowers and seed in the garden of Madrid. The stem is shrubby, four or five feet high. Leaves alternate, of numerous, uniform, smooth, elliptical leaflets, each about an inch long, glaucous beneath. Clusters axillary, drooping, simple, solitary. Flowers crimson, the size of the foregoing. Legume pointed, with narrow wings. Cavanilles describes the stamens as perfectly diadelphous, an exception to the generic character; and this circumstance, added to the abruptly pinnate leaves, and whole habit, make it probable that the plant is a *Robinia*. The same may be presumed of *P. longifolia*,

folia, Willd. n. 4. (*Æschynomene longifolia*; Cavan. Ic. v. 4. 8. t. 315.) This is a native of New Spain, and has also flowered at Madrid. The habit is very like the *punica*, but the *leaflets* are acute, and *flowers* yellow. *Legume* not observed by Cavanilles.

PISCIDIA, in *Gardening*, furnishes plants of the exotic tree kind, of which the species cultivated are the Jamaica dogwood tree (*P. erythrina*); and the Carthaginian piscidia (*P. carthaginiensis*).

Method of Culture.—These plants are capable of being increased by seeds, when they can be obtained fresh from the countries where they grow naturally. They should be sown upon a good hot-bed in the spring, and when the plants come up and are fit to transplant, be each planted in a small pot filled with light earth, and plunged into a hot-bed of tanners' bark, and afterwards treated in the same way as the other tender exotics of the same kind.

They afford variety in the stove.

PISCINA, in *Antiquity*, a large basin in an open public place or square, where the Roman youth learnt to swim; and which was surrounded with a high wall, to prevent the casting of filth into it.

The word is formed from the Latin *piscis*, *fish*; because men here imitated fishes in swimming, and because fishes were actually kept in some of these places.

PISCINA was also used for the square basin in the middle of a bath.

PISCINA *probatica* was a pool or reservoir of water, near the court of Solomon's temple; so called from the Greek *προβατων*, *sheep*; because here they washed the cattle, which were destined for sacrifice.

By this piscina it was, that our Saviour wrought the miraculous cure of the paralytic. Davilier observes, there are still remaining five arches of the portico, and part of the basin of this piscina.

PISCINA, or *lavatory*, among the Turks is a large basin placed in the middle of the court of a mosque, or under the porticos that encompass it.

Its form is usually a long square. It is built of stone or marble, furnished with a great number of cocks, wherein the Mussulmans wash themselves before they offer their prayers; as being persuaded, that ablution effaces sin.

PISCINA, the perforated stone usually found in a niche on the right hand side of the altar in our ancient churches and chapels, into which the water used in washing the hands of the officiating priests and other sacred ablutions was cast.

PISCINA, in *Geography*, a town of Naples, in Abruzzo Ultra, the see of a bishop; 18 miles S. of Aquila.

PISCIOTA, a town of Naples, in Principato Citra; 16 miles W. of Policastro.

PISCIPULA, in *Botany*. See PISCIDIA.

PISCIS, in *Ichthyology*. See FISH.

PISCIS *Australis*, in *Astronomy*. See AUSTRALIS.

PISCIS *Fossilis*, in *Ichthyology*, a name given by Johnston to a kind of the cobitis, found buried in the sand, and dug out by the people in many parts of Germany for food. It is called by many authors the *mustela fossilis*, and by some the *pacilia*. It is properly a species of cobitis, and is called by Artedi the *blucif cobitis*, with five longitudinal black lines on each side of the body. See COBITIS.

PISCIS *Sancti Petri*, a name given by Jovius and some other authors to the *faber* or *John Doree*. It is properly a species of *zeus*.

PISCIS *Volans*, the *Flying Fish*, in *Astronomy*, is a small constellation of the southern hemisphere, unknown to the ancients, and invisible to us in these northern regions. See CONSTELLATION.

VOL. XXVII.

PISCIVOROUS ANIMALS are such as feed on fish. See BIRD.

PISCO, in *Geography*, a town of Peru, in the archbishopric of Lima and jurisdiction of Ica, Pisco, and Nasca, formerly situated on the coast of the South sea, but now a quarter of a league from it. An inundation of water, occasioned by an earthquake, in October 1682, destroyed the old town, the ruins of which are still visible. The whole town contains about 300 families, most of whom are Mestizoes, Mulattoes, and Blacks; the whites being the smallest number. The road of Pisco is sufficiently spacious to accommodate a royal navy, and sheltered from the usual winds, which are those between the S.W. and S.E.; 110 miles S.S.E. of Lima. S. lat. 13° 55'. W. long. 76°.

PISCO, a town of European Turkey, in Moldavia, on a lake; 85 miles S. of Jassi. N. lat. 45° 45'. E. long. 27° 38'.

PISCO *Pagani*, a town of Naples, in the province of Basilicata; seven miles N.W. of Muro.

PISCOBAMBA, a town of South America, in the jurisdiction of Guamalies.

PISCOPIA, or TILO, a small island in the Mediterranean; 16 miles N.W. of Rhodes. This island lies nearly in the middle of the interval which separates the isle of Rhodes from that of Stancho; and is somewhat larger than Limonia and Narki. It has a tolerably good harbour, and several anchorages, which are useful accommodations for ships that frequent these seas. The ancients called it Telos, and they highly esteemed the perfumes which were there prepared. This branch of trade is lost; but it proves the goodness of the soil of Piscopia, and the mildness of its climate; circumstances the most favourable to the expansion of the sweet odour of plants and flowers. N. lat. 36° 34'. E. long. 27° 9'.

PISCOPIA, or *Episcopi*, a town of the island of Cyprus, near a river anciently called "Lycus." In its vicinity are some magnificent ruins, supposed to be those of the ancient city of Curias. The environs furnish cotton and fruit trees in abundance.

PISDRI, a town of the duchy of Warfaw; 22 miles S. of Gnesna.

PISE', a term applied to a peculiar mode of forming buildings of different kinds, but more especially those designed for farm purposes, with some sort of stiff earthy materials of a loamy quality. It is an easy, economical, and convenient method, which had its rise on the continent, and which has been had recourse to, for some time, in some parts of this kingdom, as in Bedfordshire, Lancashire, &c. See below.

PISE', *Building in*, in *Rural Economy*, the name of a method of building with loamy or other earthy matters, which has long been practised with great success, and in a very cheap manner, in some departments of France, and which is now had recourse to with similar advantage in some parts of this country. It has been described, delineated, and recommended by Mr. H. Holland in the first volume of Communications to the Board of Agriculture, and is to be managed somewhat in the manner directed below.

Sorts of Implements necessary for.—In this sort of work, in addition to the common tools, such as spades, trowels, baskets, watering pots, a plumb rule, hatchet, hammer, and nails, a mould and rammer are likewise required. The following are the different constituent parts. In the plate on pisé buildings and implements, *fig. 1.* is an outside view of the mould; *fig. 2.* inside ditto; *fig. 3.* the head of the mould, seen without; *fig. 4.* the other face, seen within; *fig. 5.* wedges; *fig. 6.* a round stick

PISE.

termed the wall-gage; *fig. 7*, post to be set upright, but seen flatwise, with its tenon; *fig. 8*, the same on its back, also with its tenon; *fig. 9*, joists in which the mortises are cut, seen flat; *fig. 10*, the same, with the side and bottom seen; *fig. 11*, a mould put together, all the parts seen, as well as a small rope; *fig. 12*, the rammer, or pifoir, for ramming the earth in mould; *fig. 13*, the side view of the same on a large scale; *fig. 14*, the plan of the instrument, seen on the top.

And in constructing the mould, it is advised to take several planks of light wood, each ten feet long, in order that the mould may be easy to handle; deal is the best, as being less liable to warp, to prevent which the boards should be straight, sound, well seasoned, and with as few knots as possible. They should be ploughed and tongued, and planed on both sides. Of these planks, fastened together with four strong ledges on each side, the mould must be made two feet nine inches in height; and two handles should be fixed to each side, as at *figs. 1* and *2*. The head of the mould, which serves to form the angles of the building, must be made of two narrow pieces of wood, ploughed, and tongued, and ledged; in breadth eighteen inches, and in height three feet; and it should be planed on both sides, as at *figs. 3* and *4*, where it will be remarked, that this part of the mould diminishes gradually to the top, in order that the wall may be made to diminish in the same degree. It is added, that all the boards and ledges must be, after they are planed, something more than one inch thick. And that the wedges, *fig. 5*, must be an inch thick, and from eight to twelve inches high; and the gage, *fig. 6*, be cut in length equal to the thickness of the wall that is to be erected.

It is still further stated, that the eight ledges which are necessary to secure the two large sides of the mould, serve also to receive eight upright posts, standing on four joists. The posts, *figs. 7* and *8* in the plate, may be made either of wood sawed square, or of round wood of any kind; so that one may use indifferently the ends of rafters, joists, small trees, or their branches. These posts are to exceed the height of the mould by eighteen inches; they must, therefore, be about five feet high, including their tenons (which should be six inches long), and three by four inches wide. That part which is to bear against the ledges of the mould must be made flat and straight, the other sides need not be worked with so much truth. And the joists may be of the same sort of stuff, three feet six inches long, three inches and a half broad, and three inches thick. On the broad part must be made the two mortises, as at *fig. 9* in the plate, ten inches and a half long, and rather more than an inch wide, and at each end three inches and a half must be left beyond the mortises, so that the interval between them will be fourteen inches. These dimensions must be observed, in order that the two sides of the mould may incline towards each other, and the thickness of the wall be gradually diminished, till it is reduced to fourteen inches at the roof. Of course the dimensions for the joists are these:

	ft. in.
The two ends, remaining beyond the mortises, } three inches and a half each -	0 7
The two mortises, ten inches and a half each -	1 9
The interval between the mortises -	1 2
Total length of the joist	3 6

It may be noticed, that the elevation of the whole machine is seen at *fig. 11* in the plate; and the following is a list of its several parts, enumerated in the same order that

the workmen must follow, when they erect the mould on a wall. A, stone foundation, eighteen inches thick, on which the wall of earth is to be raised; B, the joists placed across the foundation wall; C, C, the two sides of the mould, including between them three inches of the foundation wall; D, D, the two upright posts, the tenons of which fit into the mortises of the joist; E, the wall-gage, which fixes the width of the mould at the top, and which is shorter than the width of the wall at the bottom, to regulate the diminution of the wall to be erected; F, a small cord, something less than half an inch diameter, making several turns round the posts; G, a stick, which; by being wound round, fastens the cord, and holds the posts tight together; H, H, wedges, which enter into the mortises in the joists, and keep the posts and the mould firmly fixed against the wall. But though such is the process of erecting the mould, a contrary order must be observed in taking it to pieces. The rope must be loosened, the wedges taken out, and the posts, the mould, and the joists removed, in order to refix the whole again. And the rammer with which the earth is rammed into the mould, is a tool of the greatest consequence, and on which the firmness and durability, in short, the perfection of the work depends, and in making which more difficulty will be found than is at first apprehended. It should be made of hard wood, either ash, oak, beech, walnut, &c. or, what is preferable, the roots of either of these sorts of wood.

And in regard to the nature of this sort of work, it differs very essentially from that miserable way of building with clay or mud mixed with hay or straw, which is often seen in country villages; it contains all the best principles of masonry, together with some rules peculiar to itself. At *fig. 15*, in the plate, is represented the plan of a house, the building of which is regularly described according to this method. The foundation may be made of any kind of masonry that is durable, and must be raised to the height of two feet above the ground; which is necessary to secure the walls from the moisture of the earth, and the splashing of the rain, which will drop from the eaves of the roof. When these foundation walls are made level, and eighteen inches thick, mark upon them the distances at which the joists are to be set for receiving the moulds; those distances should be three feet each from centre to centre. Each side of the mould being ten feet long will divide into three lengths of three feet each, and leave six inches at each end, which serve to lengthen the mould at the angles of the house, and are useful for many other purposes. After having set the joists in their places, the masonry must be raised between them six inches higher, that is, to a level with the joists; here will, therefore, upon the whole, be a base of two feet and a half, which in most cases will be found more than sufficient to hinder the rain, frost, snow, or damp, from injuring the walls. Raise the mould in the manner mentioned above, immediately on this new masonry, placing it over one of the angles of the wall. The head of it, which is to be placed against the angle, should have eighteen inches in breadth at the bottom, and only seventeen inches and a half at the top; thus the sides of the mould will incline towards each other, and produce that diminution in the thickness of the wall, which is usual in buildings of this nature. The wedges must then be driven in, and the posts well fixed by cords, and the head of the mould secured by iron pins, when the whole is ready for the workmen to begin their work.

In addition it is stated, that a workman should be placed in each of the three divisions of the mould, the best being placed at the angle. He is to direct the work of the other two,

PISE.

two, and by occasionally applying a plumb-rule, to take care that the mould does not swerve from its upright position. The labourers who dig and prepare the earth must give it in small quantities to the workmen in the mould, who, after having spread it with their feet, begin to press it with the rammer. They must only receive at a time so much as will cover the bottom of the mould to the thickness of three or four inches. The first strokes of the rammer should be given close to the sides of the mould, but they must be afterwards applied to every other part of the surface; the men should then cross their strokes, so that the earth may be pressed in every direction. Those who stand next to one another in the mould should regulate their strokes so as to beat at the same time under the cord, because that part cannot be got at without difficulty, and must be struck obliquely; with this precaution the whole will be equally compressed. The man at the angle of the wall should beat carefully against the head of the mould, and for the sake of the appearance, or perhaps to increase the strength of the building, it is usual to spread every six inches high a layer of mortar near the head, in imitation of the joints of stone-work. Care must be taken, that no fresh earth is received into the mould till the first layer is well beaten, which may be ascertained by striking it with the rammer; the stroke should leave hardly any print on the place. They must proceed in this manner to ram in layer after layer till the whole mould is full. When this is done, the machine may be taken to pieces, and the earth which it contained will remain firm and upright, about nine feet in length, and two feet and a half in height. The mould may then be replaced for another length, including one inch of that which has first been completed: the regular manner of joining the different lengths may be seen in the geometrical elevations in the plate at *fig. 16*, and more particularly at *fig. 17*, where it will be observed, by the letters A and B, that no joints are left in this work, as the different lengths are united, and made to press one on the other. In the second length, and most of the following, the head of the mould is useless; it is only made use of at the angles. As soon as the workmen have gone round the whole building, taking the mould to pieces and putting it together again successively, they should begin upon the partition marked C in the same plate *fig. 15*, where the head of the mould must be used, as the door jambs are squared like the angles of the wall. The jamb next to the exterior wall, which is too narrow to be made of pisé, can easily be made of wood, brick, or stone. And the first course being thus completed proceed to the second, and here it must be observed, that if in laying the first course the work begin with one angle, as the angle A, *fig. 15*, and proceed towards E, it must, for the second course, begin with A, and proceed towards B, and so in each successive course it must proceed in a direction contrary to that of the preceding. It may easily be conceived, that with this precaution the joints of the several lengths will be inclined in opposite directions, which will contribute very much to the firmness of the work. There is no reason to fear overcharging the first course with the second, though but just laid; for three courses may be laid without danger in one day; mark the grooves for receiving the joints in the first course, at the distance of three feet from one another, but not immediately over the former grooves, but over the middle points between them, as seen at *fig. 17*, in the plate. These grooves must be cut with a pick-axe, and the second course completed in the same manner as the former, except that it must proceed in a contrary direction, as was before observed, and that the head of the mould and wall-gage must be diminished, in

order that the same inclination of the sides to one another that was given to the first course, may be preserved in this second. It must, however, be remarked, that this second course is not to be continued without interruption like the first, as it is necessary that the partition-wall should join or bond into the exterior wall; or rather, that all the walls in the building, whether outside or partition-walls, which meet at an angle, should cross each other at every course. In pursuance, therefore, of this rule, when the work has been advanced from A to C, or perhaps not quite so far as C, leave the exterior wall, and turn the mould to the partition, applying the face of it to C. This will appear more clearly by the letter G, in the same plate *fig. 17*. When the work has been carried on along the partition-wall as far as the door, bring back the mould to the part which remained unfinished in the exterior wall, marked C, at *fig. 15*, in the plate; and after having filled up that space, carry the mould on beyond the partition-wall, and complete the course. The reason of the partition-wall on the side opposite to C, not being connected in the same manner with the interior wall, is that it ought to be made of wood or brick-work, and not of this material, but the third course must be carried over the door, and join into the wall, as above. It has been observed, that this description of the two first courses is equally applicable to all the others, and will enable any person to build a house, with no other materials than earth, of whatever height and extent he pleases to have it.

Besides this, it may be remarked that the gables cannot be crossed, as these are detached from one another; but as their height is so inconsiderable, and they are besides connected together by the roof, this is not of any consequence. They may be made without any difficulty, by merely making their inclination in the mould, and working the earth accordingly. It has been observed, that each course will be two feet and a half high, if the mould is two feet nine inches; for the mould must include three inches of the course beneath. For this reason the grooves are made six inches deep, though the joists are only three inches in thickness. If the directions which have been given for diminishing the thickness of the walls are observed, that thickness will be reduced to fifteen inches at the roof, in a house (like that of which a design is annexed) consisting of six courses; for in each course there will be an inclination of half an inch. The gables might have been reduced to fourteen inches only in thickness, as an interval of fourteen inches only was left between the mortises of the joists: and by increasing or diminishing that interval the thickness of the walls may be regulated at pleasure.

It is noticed that in this mode of building, according to the account of the Rev. Mr. Jancour, as practised at Montbrison, the capital of the Forêts in France, as transmitted to the Board of Agriculture, the earth is pounded as much as possible, in order to crumble any stones therein; clay is added thereto in a small quantity, about one-eighth part. It is all beaten and mixed up together by repeated blows with a mallet about ten inches broad, ten or fifteen long, and two inches thick. The earth being thus prepared and slightly wetted, the foundation of the house is dug for; this is laid with stone, and when it is about one foot high above the surface of the ground, planks are arranged on each side, which are filled with the earth intended for the wall. It is strongly beaten; and this method is continued successively all round the building. The walls have more or less thickness, according to the fancy of the owner; he has seen them of six and of eighteen inches thick. Some builders intersperse from space to space a thin layer of lime. If several stories are intended in such erections, they do not fail

to place beams to support the floors before they build higher; the windows and doors are attended to in the same manner. Of such buildings he never saw any consisting of more than two stories at most; generally they have but one besides the ground-floor. When the building is thus finished, it is left for some months to dry: then such as wish to make the building more solid and durable, give it a rough-cast coating on the outside with lime and sand.

And in regard to the manner of forming the openings for the doors and windows, they should be left at the time of building the walls. This may be done by placing within the mould either two or one of the heads, (as represented *figs. 3 and 4* in the plate,) as may be necessary, wherever the wall is to terminate and the opening commence. They should be made sloping a little, in order to leave room for the frames and sashes. And the exterior decorations of the windows and doors are usually made, by the rich, of stone or brick, and by the poor of wood, which latter have a bad effect on the appearance of the house, as wood will never unite well with pise-work; and notwithstanding the greatest precautions, the exterior covering will break and fall off the wood; whereas stone or brick-work unite perfectly with the pise, and retain their plaster, and of course the paint, of which it forms the ground. The chimney-pieces of brick or stone are laid and united with the walls in the same manner as in common buildings; and the flues are also very firmly connected with them, being made of brick-work. But a very particular advantage is, that the apartments may be very handsomely finished, without making any jambs to the inside doors, either of stone, brick, or wood. The finishing of the earthen walls will make jambs unnecessary, and it is not requisite to be at the expence of any other finishing, as the doors may be hung on the grounds or wainscot of the apartment, as may be found necessary.

The particular Nature of, and Manner of preparing the Earth.

—It is further observed that beating, or compression, is used in many different sorts of work; the ancients employed it in making their rough walls; the Italians employ it for the terraces which cover their houses; the Moors for all their walls; the Spaniards, the French, and others, for some of the floors of their apartments. The intent of the ancient architects, when they recommended the beating of cement, and other compositions used in building, was to prevent them from shrinking and cracking; and it is employed for the same purpose in the walls which are made of earth. The beater, by repeated strokes, forces out from the earth the superfluous water which is contained, and closely unites all the particles together, by which means the natural attraction of those particles is made powerfully to operate, as it is by other natural causes, in the formation of stones. Hence arises the increasing strength and astonishing durability which houses of this kind are found to possess. It is added that upon beating a small portion of earth, and weighing it immediately afterwards, it was found to contain thirty-nine pounds and a half; fifteen days after it had lost four pounds and a quarter; in the space of another fifteen days it lost but one pound; and in fifteen days after that its weight diminished only half a pound. In the space of about forty-five days the moisture was completely evaporated, and its weight was diminished about one-eighth; consequently only one-eighth of the whole mass was occupied by moisture, and this small proportion cannot at all affect the solidity and consistency of the earth so treated. This experiment is also sufficient to shew the difference between this kind of building, and that vulgar kind called in England "mud-walling;" the latter cannot be executed without adding a great deal of water, to soften the materials employed, which

entirely destroys their consistency; the water, which occupies a considerable space in the mud, leaves, in evaporating, an infinite number of pores or little cavities, and thus the walls become weak and brittle, and incapable of supporting several stories, or such ponderous weights as the beaten earth or pise can sustain.

And with regard to the quantity or height of walling of this sort that may be done in one day, it is stated, that three courses, of about three feet each, may be laid one over the other in the course of a day; so that a wall of earth, of about eight or nine feet, or one story high, may be raised in the same time. Experience has proved, that as soon as the builders have raised their walls to a proper height for flooring, the heaviest beams and rafters may, without danger, be placed on the walls thus newly made; and that the thickest timber of a roof may be laid on the gables of this sort the very instant they are completed.

Further, on the proper sorts of earth for this use, it is stated, that, 1st. All earths in general are fit for such use, when they have not the lightness of poor lands, nor the stiffness of clay. 2dly. All earths fit for vegetation. 3dly. Brick-earths; but these, if they are used alone, are apt to crack, owing to the quantity of moisture which they contain. This, however, does not hinder persons who understand the business from using them to a good purpose. 4thly. Strong earths, with a mixture of small gravel, which for that reason cannot serve for making either bricks, tiles, or pottery. These gravelly earths are very useful; the best work of this sort is made of them. And it is said, that from the following marks may be known what earths are fittest to be employed by themselves. When these have been described, it will remain to point out such as must be mixed with others, in order that they may acquire the necessary quality. And the following appearances indicate that the earth in which they are found is fit for building: when a pick-axe, spade, or plough, brings up large lumps of earth at a time; when arable lands lie in clods or lumps; when field-mice have made themselves subterraneous passages in the earth; all these are favourable signs. When the roads of a village, having been worn away by the water continually running through them, are lower than the other lands, and the sides of those roads support themselves upright, it is a sure mark that the work may be executed in that village. One may also discover the fitness of the soil, by trying to break with one's fingers the little clods of earth in the roads, finding a difficulty in doing it, or by observing the ruts of the road in which the cart-wheels make a sort of pise by their pressure: whenever there are deep ruts on the road, one may be sure of finding abundance of proper earth. And proper earth is found at the bottom of the slopes, on low lands that are cultivated, because every year the rain brings down the fat or good earth. It is frequently found on the banks of the rivers; but above all, it is found at the foot of hills where vines are planted, and of all cultivated lands which have much slope. In digging trenches and cellars for building, it generally happens that what comes out of them is fit for the purpose of this sort of building. But as it may sometimes happen that earth of a proper quality is not to be found on the spot where it is intended to build, it becomes of importance to attend to the method of mixing earths; for though the earth which is near at hand may not of itself be proper, it is very probable that it may be rendered so by the mixture of a small quantity of another earth fetched from a distance. The principle on which a mixture must be made is very simple; strong earths must be tempered with light; those in which clay predominates, with others that are composed more of chalk and sand; and those of a rich, glutinous substance,

PISE.

with others of a poor and barren nature. The degrees in which these qualities of the earth prevail, must determine the proportions of the mixture; which it is impossible here to point out for every particular case, but which may be learnt by a little practice. And it will not be amiss to mix with the earth some small pebbles, gravel, rubbish of mortar, or in short any small mineral substances; but none of the animal or vegetable kind must be admitted. Such hard substances bind the earth firmly between them, and being pressed and pressing in all directions, contribute very much to the solidity of the whole; so that well-worked earth, in which there is a mixture of gravel, becomes so hard at the end of two years, that a chisel must be used to break it, as if it was freestone, or other solid stone.

The following experiments are detailed in order to ascertain the qualities of any earth.

Experiment 1.—Take a small wooden tub or pail, without a bottom, dig a hole in the ground of a court or garden, and at the bottom of that hole fix a piece of stone, flat and level; place your tub upon the stone, fill around it the earth that has been dug out to make the hole, and ram it well, that the tub may be enclosed, to prevent its burbling. Then ram into the tub the earth you mean to try; putting in, at each time, about the thickness of three or four fingers' breadths; when this is well rammed, add as much more, and ram it in the same manner, and so the third and fourth, &c. till the earth is raised above the brim. This superfluous earth must be scraped off extremely smooth, and rendered as even as the under part will be, which lies on the stone. Loosen with a spade the earth round the tub, and you will then be able to take it out, and with it the compressed earth that it contains; then turn the tub upside down, and if it is wider at the top than at the bottom, as such vessels usually are, the pise will easily come out; but if it should happen to stick, let it dry in the air about twenty-four hours, and you will then find that the earth is loose enough to fall out of itself. You must be careful to cover over this lump of pise with a little board; for though a shower of rain, falling in an oblique direction, will not injure it, yet it may be a little damaged, if the rain falls perpendicular, and especially if it remains upon it. Leave the lump exposed to the air, only covered with a board or flat stone, and if it continues without cracking or crumbling, and increases daily in density and compactness, as its natural moisture decreases, you may be sure that the earth is fit for building. But you must remember that it is necessary that the earth employed should be taken from a little below the surface of the ground, in order that it may be neither too dry nor too wet: it must be observed also, that if the earth is not well pressed around the outside of the tube before it is filled, though the hoops were of iron, they would burst, so great is the pressure of the beaten earth against the mould, of whatever size it may be.

Experiment 2.—This trial may be made in the house. Having brought from a field the earth you want to try, press it in a stone mortar, with a pebble of wood, brass, or iron (the latter is best); or with a hammer; fill the mortar above the edge, and then with a large knife, or some other instrument, take away the superabundance of the earth even with the brim. If you find then that the earth will not quit the mortar, you must expose it to the sun, or near a fire; and when it is sufficiently dry, it may be taken out without difficulty by turning the mortar upside down on a flat stone, or the floor. It will have the shape of the mortar, and if exposed as above directed, will shew the quality of the earth.

Experiment 3.—Press with the end of a stick, or cane, your

earth in a little box, round which you had better first tie a piece of packthread, lest it should burst in the operation; when you have filled it above its brim, cut off the overplus with a knife; you will undoubtedly be obliged to break the box to get it out, unless you had rather wait, and let it dry in the air, in the sun, or before a fire. It will take the exact form of the box, be it round, square, or oval; if your earth be red, or any other colour, that which is enclosed in the box will still remain the same. It is not improper to remark, that the colour of the earth neither adds to nor diminishes the goodness of the pise, therefore every proprietor may be at ease on that head. Besides, every person in walking on his ground, may make little balls of earth, and press them as tight as he can between his hands. If he brings them home and puts marks on them, he will by that means know the quality of every piece of land, and also be a judge of the mixture it will be necessary to make.

Further, in preparing the earth, all the operations are very simple and easy: there is nothing to be done but to dig up the earth with a pick-axe, break the clods with a shovel, so as to divide it well, and then lay it in a heap; which is very necessary, because as the labourers throw it on that heap, the lumps of earth and large stones roll to the bottom, where another man may break them, or draw them away with a rake. He must observe, that there should be an interval of about an inch and a quarter between the teeth of the rake, that the stones and pebbles of the size of a walnut, or something more, may escape, and that it may draw off only the largest. If the earth that has been dug has not the proper quality, which is seldom the case, and that it is necessary to fetch some better from a distance, then the mixture must be made in this manner: one man must throw one shovel full of the best sort, while the others throw five or six of the inferior sort on the heap, and so more or less, according to the proportion which has been previously ascertained. No more earth should be prepared than the men can work in one day, or a little more, that they may not be in want; but if rain is expected, you must have at hand either planks, mats, or old cloths to lay over the heap of earth, so that the rain may not wet it; and then as soon as the rain is over, the men may resume their work, which, without this precaution, must be delayed: for it must be remembered, that the earth cannot be used when it is either too dry or too wet, and therefore if the rain should wet it after it has been prepared, the men will be obliged to wait till it has recovered its proper consistency; a delay which would be equally disadvantageous to them and their employer. When the earth has been soaked by rain, instead of suffering compression, it becomes mud in the mould; even though it be a little too moist, it cannot be worked: it swells under the blows of the rammer, and a stroke in one place makes it rise in another. When this is the case, it is better to stop the work, for the men find so much difficulty, that it is not worth while to proceed. But there is not the same necessity of discontinuing the work when the earth is too dry, for it is easy to give it the necessary degree of moisture; in such a case it should be sprinkled with a watering-pot; and afterwards well mixed together; it will then be fit for use. It has already been observed, that no vegetable substances should be left in the earth; therefore in digging, as well as in laying the earth in a heap, great care must be taken to pick out every bit of root, great and small, all sprigs and herbs, all bits of hay and straw, chips or shavings of wood, and in general every thing that can rot, or suffer a change in the earth after it has been prepared in this manner for use in building.

The Kind of Timber necessary.—It is stated that, in order

to

to make good walls, it is not sufficient that the earths be well beaten, but they must be well united together. In houses of brick or stone, to consolidate their parts, they make use of angles and binders of free-stone, and of iron braces, and cramp irons, which are very expensive; but here the binders cost very little; they consist only of thin pieces of wood, a few cramps and nails, and these are sufficient to give the greatest stability to buildings of pise. It is added, that the first course A, *figs. 15 and 16* in the plate, being laid on the front and inner walls of a house, then begin the second; and if, for the inferior course, the mould has been directed from A to E, it must, for this second, be directed from A to F, as has been explained above. But before this second course is begun, lay at the bottom of the mould a board about five or six feet long, resting on the angle A, and extending lengthwise towards B. This board must be rough as the sawyers have left it, something less than an inch thick, and in breadth about eight, nine, or ten inches, so that there may remain on each side four or five inches of earth, if the wall is eighteen thick; by this means the board will be entirely concealed in the body of the wall. When thus placed, neither the air nor damp can reach it, and of course there is no danger of its rotting. This has often been proved by experience, as in taking down old houses of pise such boards have always been found perfectly sound, and many that had not even lost the colour of new wood. It is easy to conceive how much this board, from the pressure of the work raised above it, will contribute to bind together the two lengths A and B, and to strengthen the angle A; but this is not all, it is useful (particularly when the earth is not of a very good quality) to put ends of planks into the pise after it has been rammed about half the height of the mould. These ends of planks should be only ten or eleven inches long, to leave as before a few inches of earth on each side of the wall, if it is eighteen inches thick; they should be laid crosswise (as the plank before-mentioned is laid lengthwise) over the whole course, at the distance of about two feet from one another, and will serve to equalize the pressure of the upper parts of the works on the lower course of the pise, or rammed earth. But these boards need only be placed at the angles of the exterior wall, and in those parts where the courses of the partition-walls join to those of the exterior wall; the same directions that have here been given for the second course, must be observed at each succeeding course, up to the roof. By these means, it is seen, an innumerable quantity of holders or bindings will be formed, which sometimes draw to the right, sometimes to the left of the angles, and which powerfully unite the front walls with those of the partitions; the several parts deriving mutual support from one another, and the whole being rendered compact and solid. Hence these houses, made of earth alone, are able to resist the violence of the highest winds, storms, and tempests. The height that is intended to be given to each story being known, boards of three or four feet in length should be placed before-hand in the pise, in those places where the beams are to be fixed, and as soon as the mould no longer occupies that place, the beams may be laid on, though the pise be fresh made; little slips of wood, or boards, may be introduced under them, in order to fix them level. The beams thus fixed for each story, the pise may be continued as high as the place on which you intend to erect the roof of the building.

And beside the use of this sort of material in the building of houses, it may be applied to the raising of walls for different sorts of inclosures, as parks, gardens, yards, &c. in which the mould must be fixed in an angle, or against a

building, if the wall is to reach so far, and the workmen must proceed from thence to the other extremity of the wall; and when they have finished the first course, they must raise the mould to make the second, returning to the place where they began the first. But when a very great inclosure is to be made, as for instance a park wall, then, for the sake of speed, it is necessary to set several moulds and men at work. In such a case, a mould should be placed at each end, and the number of men be doubled; they will work at the same time, and meet in the middle of the wall, where they will close the first course; after which each set of men raise their mould to make the second; and both setting out from the middle continue working, in opposite directions, towards the ends where they first began.

In this way houses may be built, which are strong, healthy, and very cheap; and which will last a great length of time, as the author says, he had pulled down some of them, which, from the title deeds in the possession of the proprietors, appeared to be 165 years old, though they had been ill kept in repair. The rich traders of Lyons have, he observes, no other way of building their country-houses. An outside covering of painting in fresco, which is attended with very little expence, conceals from the eye of the spectator the nature of the building, and is a handsome ornament to the house. That method of painting has more freshness and brilliancy than any other, because water does not impair the colours. No size, oil, or expence is required, manual labour is almost all it costs, either to the rich or poor. Any person may make his house look as splendid as he pleases for a few pence laid out in red or yellow ochre, or in other mineral colours. And he adds that strangers, who have sailed upon the Rhone, probably never suspected that those beautiful houses which they saw rising on the hills around them, were built of nothing but earth; nay, many persons have dwelt for a considerable time in such houses, without ever being aware of their singular construction. Farmers in that country generally have them simply white-washed, but others, who have a greater taste for ornament, add pilasters, window-cases, pannels, and decorations of various kinds.

Besides, it is suggested that there is every reason for introducing this method into all parts of the kingdom; whether we consider the honour of the nation as concerned in the neatness of its villages, the great saving of wood which it will occasion, and the consequent security from fire, or the health of the inhabitants, to which it will greatly contribute, as such houses are never liable to the extremes of heat or cold. It is attended with many other circumstances that are advantageous to the state, as well as to individuals. It saves both time and labour in building, and the houses may be inhabited almost immediately after they are finished; for which latter purpose the holes made for the joists should not be closed up directly, for the air, if suffered to circulate through them, will dry the walls more speedily. And the durability of this sort of building is fully shewn by the statement of the Rev. Mr. Jancour, who resided at Montbrison in France, where, he says, the church was the most remarkable in this style of building; it is about eighty feet long, forty feet broad, and fifty feet high; the walls built in pise eighteen inches thick, and *crépé*, or rough-cast on the outside with lime and sand. Soon after his arrival, the church, by some accident, was destroyed by fire, and remained unroofed for about a twelvemonth, exposed to rains and frost. As it was suspected that the walls had sustained much damage, either by fire or the inclemency of the season, and might fall down, it was determined to throw them down partially, and leave only the lower parts standing;

but even this was not done, he adds, without much difficulty, such was the firmness and hardness these walls had acquired, the church having stood above eighty years; and all the repairs required, were only to give it, on the outside, every twelve or fifteen years, a new coating of rough-cast. And it is further remarked, that besides the advantages of strength and cheapness, this method of building possesses that of speed in the execution. It is found that a mason used to work, can, with the help of his labourer, when the earth lies near, build, in one day, six feet square of the pise. If two men can build, in one day, six feet square, it is evident that six men, which is the necessary number to work the mould, (*viz.* three in the mould, and three to dig and prepare the earth,) will build, in the course of sixteen days, or three weeks at most, such a house as is seen in the plate, at *figs.* 15 and 16, containing 228 square feet of wall; a very short time therefore is sufficient for a man to build himself a solid and lasting habitation. These facts, which have been proved by numberless instances, afford a proportion by which every one may determine the time that his house or wall will take in building, having first ascertained the number of feet it will contain. Thus, if he wishes to have a wall 540 feet long, and six feet high, it will be finished in one month, with one single mould, and six men; but if he doubles both mould and men, it will be done in fifteen days. These are simple but necessary instructions, for they will prevent the inconvenience to which many are exposed from having the completion of their building protracted beyond the time that they originally expected. All persons who wish to build, may now contract with the builder that the work shall be finished on such a day; or that he shall indemnify them for all the losses which they may incur from his failure to make good his engagement in that respect.

And in regard to the outside covering of plaster, which is proper for rammed earth or pise walls, it is quite different from that which is made use of on any other walls: it is necessary, too, to take a proper time for laying it on. When a house of this sort has been begun in February, and completed in April, the covering may be laid on in the autumn, that is to say, five or six months after it is finished; or if it is finished in the beginning of November (at which time the masons generally give over working) it may be laid on in the spring. In this interval the walls will be sufficiently dried; but it must not be imagined that it is the drought or cold that extracts the moisture from an earthen wall; it is only the air, which is of itself sufficient either in summer or winter, to dry a pise or rammed-earth wall thoroughly. If the plaster be laid over them before the dampness is entirely gone, it must be expected that the sweat of the walls will cast it off.

But in order to prepare the walls for plastering, they should be indented with the point of a hammer, or hatchet, without being afraid of spoiling the surface left by the mould; all those little dents must be made as close as possible to each other, and cut in, from top to bottom, so that every hole may have a little rest in the inferior part, which will serve to retain and support the plaster. And to do it the masons must make a small scaffold in the holes which the joists of the mould have left at *figs.* 2 and 3 in the plate. This scaffold may be made in a few minutes, and when, with the assistance of it, they have indented the upper parts of the house, they must run a stiff brush over the indented surface, to remove all dust or loose earth. The walls, when thus prepared, may receive the plastering; but it should be observed that there are two kinds of plaster that may be used in the pise; rough-cast, and stuccoing. Rough-cast consists of a small quantity of mortar, diluted with water in a tub, to

which a trowel of pure lime is added, so as to make it about the thickness of cream. Stucco is nothing more than poor mortar, which the labourers make up in a clean place near the lime-pit, and carry it to the masons on the scaffold.

Besides, for the purpose of rough-casting one workman and his labourer are sufficient; the workman only sprinkles with a brush the wall he has indented, swept, and prepared; after that he dips another brush, made of bits of reed, box, &c. into the tub which contains the rough-cast, and throws with this brush the rough-cast against the wall; when he has covered, with as much equality as possible, so much of the wall as is within his reach, he lowers his scaffold, and stops up the holes of the joists with stones, or old plaster, &c. does as before, and continues lowering his scaffold in the same manner till he comes to the bottom of the house. This rough-cast, which is attended with so little trouble and expence, is notwithstanding the best cover that can be made for pise or rammed-earth walls, and for all other constructions; it contributes to preserve the buildings, and though not beautiful, has the recommendation of being attainable by people in moderate circumstances. It is the peculiar advantage of these buildings that all the materials they require are cheap, and all the workmanship simple and easy to be performed.

But in regard to the process of stuccoing it is very different; two workmen and two labourers are requisite, the two workmen being on the scaffold, and one of the labourers making up the mortar, while the other carries it with water, and serves the workmen. One of the workmen holds in his right hand a trowel, and in the other a brush, with which he sprinkles the wall, having beforehand indented and swept it; after that, he lays on a few trowels full of stucco, which he spreads as much as possible with the same trowel, and then he lays on more, and thus continues his work. The second workman has also in his left-hand a brush, and in his right-hand a small wood float; he sprinkles water over the mortar that his partner has spread, and rubs over that part he has wetted with his wood float. Thus the first workman lays on the plaster, and advances gradually, the second follows and polishes; one labourer makes up the stucco, the other carries it, and serves the workmen. By this process the smoothest, finest, and cheapest plastering is made. And at the same time that the plaster is laid on, it may also be whitened by the use of lime alone, which is also an object of economy, since it saves white lead, &c. For this purpose dilute lime in a tub of very clear water, and let a labourer take some of it in a pot, and carry it to the workmen, who must lay it on with a brush; this, as well as all other colours, adheres to the plaster, and never falls, although it is used with water only, without size or oil. This is to be attributed to the precaution of laying on the colour whilst the plaster is still wet; as it grows dry, it incorporates the mineral colours with its own substance, and makes them last as long as itself. This is on the principles of fresco colouring or painting, which is very neat.

And it is added, that the lime is of very general utility; it is used in building, in plastering, and in white-washing; and it will appear that for painting also it may be employed with advantage. Those who intend to build, therefore, ought always to have a store of it by them, and it should be slaked a long time before it is used, to prevent crevices and blisters, which, without this precaution, will arise in the plaster, and give it so disagreeable an appearance, that it will be necessary to do the work over again. The reason of it is this, there will always remain in the lime some particles that have not been slaked in the pit; all the stones are not

entirely reduced to lime in the kiln, and those stones will resist the action of the water for a time, and will burst from the plaster after it has been laid, leaving the crevices above-mentioned. This inconvenience will not happen if the lime, after being slaked, is left to stand some time before it is used. Indeed it will not be amiss to let it lie by a whole year, or longer, when it can be done with convenience. Besides this, it is observed on the painting in fresco of the outside covering, that that kind of painting which is known by this name, is the most beautiful and cheapest of any, and it is that which the author recommends for the decoration of pisé or rammed-earth buildings. The most celebrated painters were very partial to it, and Rome furnishes many excellent models, which should engage us to restore it from that neglect and disuse into which it has, without reason, been suffered to fall. And that, whoever wishes to have his house painted in fresco, must have a painter ready, and place him on the scaffold with the workmen. The latter lay on the mortar, as before directed, and are attentive to spread it very even, to receive the paint. When they have finished one part, they suspend their work, to give the painter time to do his; for if they continued working on, the painter, who cannot go on so fast as they, would find the mortar too dry, and the colours would not incorporate with it. It is absolutely necessary that the plasterer's work should be subordinate to that of the painter; it is sometimes so arranged, that the latter work while the former are gone to their meals; and when in his turn he retires from work, he traces out the part that the plasterers are to cover during his absence, foreseeing how much he shall be able to paint in the course of the day. All these precautions are taken to prevent the too speedy drying of the mortar, and to seize the proper time to lay on the colours while it is fresh.

And in order to make the colour meant to be given to a country-house, dilute in a large tub a sufficient quantity of lime which has been slaked a long time; and also dilute in another tub or pot some ochre, either yellow, red, or any other mineral colour, but always in very clear water; after which, pour a little of the colour into the large tub, and stir it about with a stick, so as to mix it well with the lime; take some of the colour on a brush, and try it on a board or wall; if it is too deep or too light, add fresh lime or colour from the tub, and by repeated trials bring it to the tint that is wished to be given to the house. The colour being made for the body of the house, the frames of the doors and the windows are next to be considered, and a new colour chosen, to distinguish them from the rest of the front. If the body of the house is painted yellow, or of a pale red, the angles and frames may be white or blue; if it is grey, they may be yellow or deep red, and in all cases it will be a very easy matter to find the most suitable colours. It is added, that the plasterers are equal to painting the fronts of houses in a common way; but when builders or proprietors wish to have them decorated in a superior manner, they must call in a painter, whose business it is to do it. The writer asserts that these paintings in fresco are more lively and more brilliant than any other; because the colours are not deadened by size or oil, which do not enter into their composition; their effect is surprising, and may be had at a little expence. And in concluding, it is remarked that the plaster proper to serve as a ground for fresco painting or colouring, is made of one part lime and three parts clean, sharp, washed sand; also that this sort of painting has lately been executed with great success at Woburn Abbey, and some other places in this country. It is not very usual, it is observed, to slake the lime in this

country so long before it is wanted; but it is an excellent practice, especially if it be wood-burnt.

In short, this method of building seems, from its cheapness and durability, and the readiness with which it is executed, to deserve the attention of the proprietors of lands in this kingdom, as the means of raising comfortable houses for their labourers and cottagers, which, from the increased prices of the usual sorts of building materials, are now become seriously expensive in providing.

Some different kinds of buildings of these earthy materials may be seen at Woburn Abbey, the seat of the duke of Bedford, and in some other places.

There are other neat buildings of the cottage kind, formed and raised in this way, which may be seen in *Plate XXII.* in the second volume of the *Farmer's Dictionary*, under the head *Pisé Cottages*, with different elevations, ground plans, &c.

Others likewise built with the common sorts of materials, but which may be raised equally well and conveniently in pisé work, are represented at *figs. 1, 4, and 7, in Plate VII.* on *Agriculture*, under the title of *Ornamental Cottages*, in which *figs. 2, 5, and 8,* shew the ground plans, and *figs. 3, 6, and 9,* those of the upper rooms. These kinds of cottages would have an extremely neat and ornamental appearance when erected in the latter of these methods, about the entrances of parks and other kinds of pleasure grounds, as well as near any large country residences, and at the same time be built at an easy expence.

PISEK, in *Geography*, a town of Bohemia, in the circle of Prachotitz, on the Watawa; 20 miles N. of Prachotitz. N. lat. 49° 22'. E. long. 14° 36'.

PISHAMIN PLUM, in *Botany*. See *Indian Date PLUM*.

PISIDIA, in *Ancient Geography*, a province of Asia Minor, N. of Pamphylia, separated by a chain of mount Taurus from Isauria.

PISIFORME OS, in *Anatomy*, one of the bones of the carpus. See *EXTREMITIES*.

PISIG, in *Geography*, a small island in the East Indian sea. N. lat. 2° 20'. E. long. 125° 1'.

PISIGNANO, a town of Naples, in the province of Otranto; four miles S.E. of Lecce.

PISILIS, in *Ancient Geography*, a town of Asia Minor, in Caria, between the river Calbis and the town of Caunus, according to Strabo.

PISINDA, a town of Africa Propria, placed by Ptolemy among those which lay between the two Syrtes.—Also, a town of Asia, in Pamphylia, placed by Ptolemy in that part of this country which was called Carbalia.

PISINGARA, a town of Asia, in the Lesser Armenia, placed by Ptolemy at a distance from the Euphrates towards the mountains.

PISISTRATI INSULÆ, three islands on the coast of Ionia, near Ephesus, called by Pliny Anthinæ, Myonnesos, and Diarrheusa.

PISISTRATUS, in *Biography*, an eminent Athenian citizen, was of noble descent, which he derived from Codrus, the last king of Athens, and inherited a large property from his father Hippocrates. He possessed the natural advantages of a commanding person, a ready elocution, and an uncommon capacity, which he improved with the utmost diligence. Entering into public life, he promoted, by his eloquence, the endeavours of Solon to rousing the Athenians to the recovery of Salamis, and he accompanied that legislator in the successful expedition for the purpose. Naturally ambitious, he ingratiated himself with the lower classes of citizens by the most winning affability, and bound-

lefs liberality. He relieved their necessities, fet open his gardens, and in all his discourfes he was the advocate of political equality, and the democratic constitution. Solon and others faw through the artifice of his conduct. Pisistratus one day haftily appeared in the market-place, bleeding from fome flight wounds which he had inflicted on himfelf, and loudly implored the protection of his fellow-citizens from pretended enemies, who were, he faid, purfuing his life, on account of his attachment to the democracy. From this time he obtained a guard to attend his perfon for his fecurity. This guard he foon employed to feize the eitadel. He difarmed the multitude, and was now the undoubted mafter of Athens, while Solon, who had refifted his tyranny in vain, departed from his enslaved country. This event occurred B.C. 560. Though Pisistratus juftly incurred the charge of tyranny by the mode which he adopted to acquire his power, he by no means ufed that power in an offensive way. On the contrary, it is thought, that very few lawful fovereigns ever conducted themfelves with greater moderation, or with more regard to the beft interefts of his countrymen. He did not in the leaft attempt to abrogate the wife laws of Solon, but invested them with additional authority, and he always expreffed great veneration for the legiflator, whom he intreated, but in vain, to return to Athens. His fupremacy, however, was not as yet well fecured, and attempts were made by Megacles to overthrow his power. He fucceeded, and Pisistratus was obliged, in his turn, to become an exile, while his property was put up to public fale. Afterwards Megacles permitted him to return, on condition that he would marry his daughter, to which Pisistratus readily acceded, though he refufed to live with her, which fo far exasperated the father-in-law, that to avoid his vengeance he retired to Eretria. He there occupied himfelf in preparations for the recovery of his authority by force, which he effected in the eleventh year of his fecond exile. From this time he continued to govern with the fame lenity; but in order to weaken the popular party, he obliged many of the idle inhabitants to leave the city and engage in the cultivation of the furrrounding diftrict: and by exacting the tenth of every man's income and produce, he augmented the public revenues, which he expended on magnificent buildings. He alfo ftudied to foften the minds of the Athenians by the encouragement of literature. He founded a public library, and made a collection of the poems of Homer, which were at that time fcattered in detached parts throughout Greece, and digefted them into the order which they have fince preferved. Senfible of the odium attaching to a tyranny, he was careful to mafk his power under the demeanour of a citizen, and in this way he exercifed the fovereignty during the remainder of his life, regarded rather as the father than the oppreffor of his country, which fcarcely ever enjoyed a longer period of quiet and profperity. He died in the year 527 B.C., leaving his fons, Hippias and Hipparchus, the heirs of his power. Univer. Hift.

PISKOI, in *Geography*, a town of Ruffia, in the government of Archangel, on the river Mezen; 188 miles E. of Archangel.

PISMIRE, in *Zoology*. See **ANT**.

PISO, **L. CALPURNIUS**, in *Biography*, furnamed *Frugi*, a Roman of a diftinguifhed patrician family, called the Calpurnian, according to Cicero; though in another paffage he represents him as the fon of a tribune. The epithet *Frugi* is faid to have been given him on the following occafion. When conful in the year 183 B.C., he went into Sicily in order to fupprefs a mutiny among the flaves, and after the bufinefs was effected, beftowing commenda-

tions from the tribunal on thofe who had chiefly contributed to the fuccefs, he awarded to his own fon the prize of a golden crown of three pounds weight, faying, at the fame time, that he meant to leave him the gold as a legacy, fo that he fhould receive the honour from his generals, and the reward from his father. For this instance of frugality of the public money, the appellation of *Frugi* was beftowed upon him. In proof of the exactnefs of the principles of juftice by which he was governed, we have the following anecdote. He had always oppofed the law for the gratuitous diftribution of corn, but when it had been carried by C. Gracchus he came to demand his portion. Gracchus perceiving him ftanding in the crowd, asked him how he could be fo inconfiftent as to receive corn by virtue of the law which he had oppofed. To this he replied, "It was againft my will that you fhould have the diftribution of my property, but if it muft be fo, I will claim my fhare of it." Pifo was afterwards cenfor with Metellus Balearicus. He pleaded caufes, and was a promoter or oppofer of feveral laws. He left behind him various orations, and was the author of "*Historical Annals*," which, though written in the meagre fimplicity of the times, were reckoned of good authority.

PISO, in *Commerce*, a weight ufed on the coaft of Guinea. A feron is $1\frac{1}{2}$ pifo, and a pifo is fubdivided into $1\frac{1}{2}$ quintos, 2 agragues, or 4 media-tablas.

PISOGNE, in *Geography*, a town of Italy, in the department of the Benaco; 20 miles N.N.W. of Brefcia.

PISOLITE, in *Mineralogy*, a flaty artificial calcareous ftone of a grey colour, arifing from calx of iron. See **LIME-Stone**.

PISONIA, in *Botany*, received that appellation from Father Plumier, in memory of William Pifo, a phyfician of Leyden, the companion of Marcgraf, but whether his mafter or fervant remains in difpute. (See **MARCGRAVIA**.) Pifo furvived Marcgraf, but of the time of his death, or of his age, we find no account.—Plum. Gen. 7. t. 11. Linn. Gen. 551. Schreb. 739. Willd. Sp. Pl. v. 2. 283. Mart. Mill. Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped; its limb in five acute, equal, fpreading, folded fegments, permanent. *Cor.* none. *Stam.* Filaments more numerous than the fegments of the calyx, ufually from fix to ten, prominent, awl-shaped; anthers roundifh, two-lobed. *Pift.* Germen fuperior, oblong; fyle fimple, cylindrical, longer than the calyx; ftigma cloven. *Peric.* Capfule oval, of one cell, without valves, clothed with the permanent pentagonal tube of the calyx. *Seed* folitary, fmooth, oblong.

Efl. Ch. Calyx bell-shaped, five-cleft, plaited. Corolla none. Capfule of one cell, without valves, clothed by the angular calyx. *Seed* folitary.

Obf. The ftamens on one plant, and the piftils on another, are more or lefs imperfect, fo that the genus is, in effect, dioecious, or at leaft polygamous; but it is one of thofe which, having no other difference of ftructure in their flowers, but, on the contrary, the rudiments at leaft of both organs prefent in every flower, are beft claffed by the number of their ftamens. In this latter refpect however *Pifonia* is uncertain, like its relations *Mirabilis*, *Valeriana*, and *Boerhavia*.

1. *P. aculeata*. Prickly Pifonia, or Fingrigo. Linn. Sp. Pl. 1511. Ait. n. 1. Plum. Ic. t. 227. f. 1. (Pa-

liuro affinis arbor spinosa, &c.; Sloane Jam. v. 2. 25. t. 167.)—Spines axillary, horizontal. Leaves ovate, acute at each end, smooth. Calyx of the fruit prickly.—Native of the West Indies. A tree whose trunk is as thick as a man's thigh, eight or nine feet high, with weak drooping spinous branches. Leaves nearly opposite, stalked, simple, entire, smooth, pointed, two or three inches long and one broad, deciduous. Flowers appearing before the leaves in dense downy panicles, about the ends of the branches, yellowish-green, bracteated, small, smelling like elder. Fruit club-shaped, its angles beset with numerous, regular, obtuse, prickles, the panicle being enlarged and divaricated.

2. *P. subcordata*. Heart-shaped Fingrigo, or Loblolly-tree. Swartz Ind. Occ. v. 2. 641. Willd. n. 2.—Spines none. Leaves roundish-heart-shaped. Calyx of the fruit dry, its angles prickly in the upper part.—Native of Antigua, St. Kitt's, &c. A tree, with unarmed, smooth, brittle branches. The wood is of little use, whence, according to Swartz, it is called *loblolly*, an appellation given in the West Indies, to a number of trees whose wood is good for nothing. Leaves stalked, opposite, smooth, turning black in drying. Cymes axillary, stalked. Flowers minute, greenish, polygamous. Stamens seven.

3. *P. nigricans*. Black-berried Fingrigo. Swartz Ind. Occ. v. 2. 643. Willd. n. 3. Ait. n. 2. (*P. inermis*; Jacq. Amer. 275.)—Spines none. Leaves ovate, pointed, smooth. Flowers cymose, erect. Calyx of the fruit pulpy, smooth.—Native of mountainous woods in Jamaica and Hispaniola. Swartz. Jacquin says it is frequent about Cartagena. A small tree, or shrub, ten or twelve feet high, with smooth branches, destitute of thorns. Leaves stalked, opposite, smooth on both sides. Cymes stalked, terminal and axillary, of many small yellowish-green upright flowers, with two or three minute acute bractes at the base of each. Fruit oval, smooth, black, the tube of the calyx which clothes it becoming pulpy as the seed ripens, but there are no prickles upon it.

4. *P. coccinea*. Scarlet-berried Fingrigo. Swartz Ind. Occ. v. 2. 645. Willd. n. 4.—Spines none. Leaves elliptic-lanceolate, smooth. Panicles terminal, loose. Flowers drooping. Calyx of the fruit pulpy, smooth.—Native of bushy places in Hispaniola, flowering in May. Sw. A shrub, or small tree, with smooth, round, unarmed branches. Leaves scattered or opposite, on longish slender stalks, and tapering at each end; paler beneath. Flowers whitish-brown, small, drooping, with three linear bractes at their base. Stamens seven, rarely eight or ten. Fruit oblong, smooth, pulpy, scarlet. We have an authentic specimen of this from Dr. Swartz. If we are right in a specimen in the herbarium of the younger Linnæus, which we presume to be the *nigricans*, that species differs from *coccinea* in having much shorter and broader footstalks, as well as far more numerous and straight transverse veins to the leaves, which latter are obovate, rather than ovate. The fruit is smooth, oblong, in a long-stalked spreading panicle. Probably the stalk is elongated after flowering, as Swartz describes it shorter, in that state, than the leaves.

5. *P. mitis*. Small-thorned Pifonia. Linn. Sp. Pl. 1511. Willd. n. 5. (*P. inermis*; Swartz Obf. 393. Katukava walli; Rheede Hort. Mal. v. 7. 13. t. 17, on the authority of Linnæus.)—Spines axillary, curved. Leaves ovate, downy. Calyx of the fruit downy, without prickles. Native of the East Indies. Koenig. This has the habit of the first species, but the spines are fewer, smaller, and curved. Leaves opposite or aggregate, alternate on the young shoots, ovate, or elliptic-lanceolate, with a blunt point, obscurely veined, clothed, more or less densely, with

short rusty down. Footstalks downy, a quarter the length of the leaves. Flower-stalks axillary, often two together, longer than the leaves, downy, with opposite branches all towards their ends, bearing dense tufts of small downy flowers, with ovate downy bractes. Stamens seven. Panicle of the fruit more lax and spreading. Fruit obovate, clothed with the downy tube of the calyx, destitute of prickles. As we unfortunately have not access at present to the seven latter volumes of the Hortus Malabaricus, we cannot examine into Rheede's synonym, but our specimens having spines, one part of the difficulty, which has so much embarrassed authors, is removed. The Linnæan herbarium has no marked specimen; but the species seems to us perfectly clear in its characters and history. Poirer, in Lamarck, has confounded it, under the faulty name of *inermis*, with the *nigricans* of Swartz.

6. *P. grandis*. Superb Pifonia. Brown Prodr. Nov. Holl. v. 1. 422. Ait. n. 3.—“Stem arborescous. Leaves oblong, pointed, smooth. Cymes compound. Flowers polygamous. Stamens from seven to nine. Calyx of the fruit prickly.”—Found by Mr. Brown in the tropical part of New Holland, and brought in 1805 to Kew, where it is kept in the green-house, but has not yet blossomed. We have seen no specimen.

7. *P. villosa*. Broad-leaved Pifonia. Poirer in Lamarck Dict. v. 5. 347?—Leaves ovate, obtuse, somewhat downy. Panicles dense, repeatedly branched, downy. Calyx very slightly divided.—Native of the island of Mauritius. Our specimen came from Thouin's herbarium. The bark of the branch is smooth, without thorns. Leaves two or three inches long, and half as broad, stalked, ovate, obtuse, wavy, thinly covered with fine short pubescence, which perhaps disappears at a more advanced period. Flowers very numerous, in dense, round, stalked, downy panicles, whose copious subdivisions are alternate. Calyx abrupt, club-shaped, downy. Anthers large, reddish. We have seen no fruit. Our only doubt is whether Poirer's plant may not be our *mitis*. We have therefore described our own specimen, without borrowing any thing from him, and to this, in either case, the name of *villosa* may remain. Our's has all the appearance of being one of Sonnerat's specimens. As it is the young extremity of a branch, the spines may well be wanting.

The *P. subovata*, Poirer n. 4, is an accidental error for *subcordata* of Swartz.

The beautiful BUGINVILLEA of Commerçon, see that article, is very nearly allied to *Pifonia*. Its curiously twisted limb of the calyx, in the ripening fruit, is not represented by Lamarck, though it may have some weight in the generic character.

PISONIA, in Gardening, contains plants of the exotic tree kind for the stove, of which the species cultivated is the prickly pifonia (*P. aculeata*.)

Method of Culture.—It is increased by seeds, which should be sown in pots filled with light rich earth, and plunged into a hot-bed of tanners' bark; and when the plants come up, they should be transplanted into separate pots, and plunged into the hot-bed again, where they may remain till autumn, when they should be removed into the stove, and plunged into the bark-bed, and treated in the same manner as has been directed for several tender plants of the same country; in hot weather giving them plenty of water, but in winter more sparingly.

They are too tender to thrive in the open air of this country at any season of the year, they should, therefore, be constantly kept in the stove. They retain their leaves most part of the year in this climate.

The plants afford variety in stove collections of exotic plants.

PISONOS, in *Ancient Geography*, a town of Asia, in Lesser Armenia, on the route from Sebaste to Cocufon, between Ad Prætorium and Melitene, according to the Itinerary of Antonine.

PISRAH, in *Geography*, a town of Hindoostan, in Bahar; 58 miles S.S.W. of Patna.

PISSA, a town of Prussian Lithuania; four miles S. of Stalluponen.—Also, a river of Prussia, which runs into the Pregel, near Inster.

PISSANIZENA, a town of Prussia, in Natangen; 10 miles S. of Marggrahowa.

PISSASPHALTUM, or **PISSASPHALTUS**, *πιτσασφαλτος*, compounded of *πιτσα*, *pitch*, and *ασφαλτος*, *bitumen*, found in *Natural History*, denotes a native, solid bitumen, found in the Ceraunian mountains of Apollonia: of an intermediate nature between pitch and asphaltum. Its characters are these: the pissasphalta are fluid mineral bodies, of a somewhat thick consistence, dusky, and opaque; of a strong smell, and readily inflammable, but leaving a residuum of greyish ashes after burning.

There are three known species of this genus. 1. A thinner blackish kind, called *oleum terra*, and *petrol*. 2. A thicker black one, called *pisselæum Indicum*, or *Barbadoes tar*. And, 3. A black and viscous one, called simply *pissasphaltum* in the shops. See **BITUMEN**.

Pissasphaltum is as tough and viscous as bird-lime, and of the same consistence when old. It very much resembles the common black pitch, when softened a little by heat; and has been generally thought to have something of the smell of that substance; but this seems to have arisen from its being too frequently adulterated by mixing pitch with it, and the true genuine substance has no other smell than the rank one of all the bitumens, which somewhat resembles that of oil of amber. It is produced in several parts of the world, and there are large quantities of it in Germany, in Persia, and in France. It yields a limpid oil by distillation, which very much resembles the native petroleum, and is too often sold with us under this name, being annually imported in large quantities from those parts of Germany where it is manufactured, and having itself no particular name in the shops of our druggists.

Pissasphaltum was much recommended by the ancients for external use, as an emollient, maturant, and digestive: with this intention it was used in cataplasms, for ripening all sorts of tumours, and against the sciatica and other pains of the limbs. They also had recourse to it for strengthening the limbs, after the reduction of dislocations. It is little used at present, the petroleum being thought very proper to supply its place.

PISSASPHALTUM is also a name given to a factitious substance, compounded of pitch and asphaltus, or the true bitumen Judaicum.

The coarseness of this, the black colour, and the fetidness of the smell, distinguish it from the true asphaltum.

PISSASPHALTUM is also used, by some writers, to denote the Jewish pitch, or simple asphaltum.

PISSELÆUM, *πισσελαιον*, *oleum Picinum*, or oil of pitch, an obsolete medicament compounded of oil and pitch.

PISSELÆUM Indicum, among *Modern Writers*, denotes a bituminous substance brought from the West Indies, particularly called *Barbadoes tar*.

It is a heavy, thick, and dusky-looking mineral fluid, of the colour and consistence of common treacle, and of a very opaque hue; it is of a disagreeable smell, faintly approaching to that of oil of amber, and is very inflammable. It is found trickling down the sides of the mountains at the

back of several of our plantations in America, and is in great esteem there for coughs and disorders of the lungs. We meet with very little in England that is genuine, several different sophistications of it being in common use, even upon the spot. (See **BITUMEN**.) It has a strong smell not unlike the common tar, and is not very pleasant to fight or taste. It is accounted a good balsamic, and where the stomach can dispense with it, will do great service in many disorders of the breast, which has also been experienced of common tar.

PISSER, in *Geography*, a mountain of the county of Tyrol; four miles S.E. of Landeck.

PISSEROS, the name of an ointment greatly recommended by Hippocrates in many cases, as in burns, fresh wounds, &c. It was made of oil of roses, bees-wax, and pitch, proportioned so as to give the whole a soft consistence. It was of the nature of our modern black basilicon, and found a good ointment in many cases.

PISSINUM. Pliny says it was customary for the ancients to hold fleeces of wool over the steam of boiling tar, and squeeze the moisture from them, which watery substance was called *pissinum*.

Ray will have this to be the same with the pisselæum of the ancients; but Hardouin, in his notes on Pliny, thinks the pisselæum to have been produced from the cones of cedars. What use they made of these liquors anciently, is not known; but it may be presumed they were used in medicine, though at present it does not appear they are used at all.

PISSITES, a name given by the ancients to a wine impregnated with the virtues of liquid pitch or tar. To prepare it, the tar was ordered to be washed in sea-water or brine, and afterwards in fresh water many times; and after a tedious preparation of this kind, two ounces of it were ordered to be put to eight gallons of mull, which is to be suffered to work together, and the clear liquor to be bottled off.

This was accounted a warm wine, very assitant to concoction, and of an absterfiv faculty, and a good pectoral: on these accounts it was given in disorders of the breast, and in obstructions of the liver, spleen, and uterus, if not attended with a fever; and was a common medicine in coughs and asthmas of all kinds.

PISSOCEROS, a name given by the old naturalists to a substance found very frequently in the hives of bees, and consisting of a mixture of propolis and wax. The ancients were well acquainted with the use of this substance, which was used for stopping up the cracks and chinks in the hives: they mention, indeed, three sorts of matter used by the bees for this purpose; the metys, the pissoceros, and the propolis; but later authors call them all by the general term propolis, the pissoceros and metys being only the same substance, mixed with wax in different proportions. This propolis is a resinous substance, of a soft and viscous consistence, collected from the beds of the poplar and other trees.

PISSOS, in *Geography*, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marsan; 27 miles N.W. of Tartas. The place contains 1338, and the canton 4572 inhabitants, on a territory of 482½ kilometres, in seven communes.

PISSOSIS, a word used by the old writers on medicine for the depraved appetite of young women about the first eruption of the menses, and of some women with child.

PISS-POT BAY, in *Geography*, a bay in the straits of Magellan. S. lat. 53° 14'. W. long. 75° 12'.

PISTACHIA-NUT, in *Botany, Gardening, &c.*, a well known sort of nut. See **PISTACIA**.

PISTACHIA, or *Pistach-nut*, a fruit brought from several parts

parts of Asia, chiefly from Aleppo and Persia. When wrapt in all its coats, it is of the size of a green almond; but when stripped of all but its shell, it resembles a small nut. The kernel is red without, and green within; its taste is very agreeable.

The word is formed from the Latin *pistacium*, of the Greek *πιστάκιον*, whence, according to Menage, the city Pistacium took its name.

The tree that produces it is a kind of turpentine-tree. See PISTACIA.

The nuts are to be chosen new, heavy, and full; as to those that are broken, such as have kept their colours best are to be preferred; for nothing depends upon the size.

Pistachias have been reckoned aperitive, and proper to give vigour; and used in emulsions, &c. in phthical and nephritical cases. They also enter several ragouts, and are comfited, made into conserves, &c. There is likewise a kind of false pistachia, brought from the Caribbee islands, which some confound with the real ones, though very different, both with regard to the plants that produce them, and their quality. The spurious pistachia plant does not rise above a foot high; nor does the fruit grow on the branches, but is found in pods. The pod sometimes only contains a single nut, which resembles an olive; but usually several; and in that case they are irregular. The substance is white, compact, and heavy.

This fruit is rarely eat raw, because of the ill effects it produces; it is usually roasted or comfited; it is used in ragouts, and to make ratifias.

PISTACHIA-Tree, *Black Virginian*, a species of the *hamamelis*; which see.

PISTACIA, in *Botany*, *πιστάκιον* of Dioscorides, a word of doubtful origin. Athenæus attributes it to the Syrians. Forkall gives *fofluk* as the Arabic name of the *Lentiscus*, and Olaus Celsius of the *Pistacia*; hence De Theis supposes *πιστάκιον* a corruption of that word; but surely it is hazardous enough to presume them of one common origin. Rauwolf's *fyluc* indeed comes much nearer.—Linn. Gen. 518. Schreb. 683. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 381. Lamarck Illustr. t. 811. (Terebinthus; Tourn. t. 345. Juss. 371.)—Class and order, *Diocia Pentandria*. Nat. Ord. *Amentacea*, Linn. *Terebinacea*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in five deep equal segments. *Cor.* none. *Stam.* Filaments five, capillary, very short, spreading; anthers large, oblong, quadrangular, obtuse, of two cells bursting lengthwise, spreading.

Female, on a separate plant, *Cal.* Perianth of one leaf, inferior, in three deep equal segments, deciduous. *Cor.* none. *Pist.* Germen superior, roundish, somewhat triangular; styles three, erect; stigmas spreading, obovate, thickish, hispid, undivided. *Peric.* Drupa dry, coriaceous, ovate. *Seed.* Nut ovate, smooth.

Eff. Ch. Male, Calyx five-cleft. Corolla none. Female, Calyx three-cleft. Corolla none. Styles three. Drupa dry. Nut single-seeded.

Obs. Linnæus considers the male flowers as constituting a catkin. Jussieu concretely terms it *racemus amentaceus*. The inflorescence is actually a panicle, with a bractea under each of its subdivisions, in both sexes; which is proved by the presence of a true perianth to each flower in each.

1. *P. officinarum*. Pistachia-nut Tree. Ait. n. 1. (Pistacia; Matth. Valgr. v. 1. 248. Bauh. Hist. v. 1. par. 1. 275. Ger. em. 1436. Pistachi, fistuc of the Arabians; Rauw. It. 72. t. 9. Terebinthus indica Theophrasti, Pistacia Dioscoridis; Tourn. Inst. 580. Duham. Arb. v. 2. 306. t. 88.)—Leaves simple, ternate, or pinnate; leaflets oval. Fruit ovate, pointed.—Native of Syria, and other

countries in the Levant. Matthioli says the Venetians usually imported the nuts from Syria. The tree has often been raised in this country, and as often lost. It is marked as hardy in Hort. Kew. flowering in April and May. We have had no opportunity of seeing more than a dried specimen, without flowers. The young leaves are ternate, the more advanced ones pinnate; the leaflets elliptical or ovate, pointed, slightly wavy, entire, smooth, except a fine, chiefly marginal, pubescence when young. Their midrib sends off several parallel transverse veins, connected by fine reticulations. Fruit paniced, about an inch long, ovate, with an oblique point, reddish, well known, for the sake of its nut, at our tables. The green internal hue of the kernel is remarkable. Linnæus's history of this plant is so extremely confused, that we have judged it best to follow Mr. Aiton in its name, rejecting the synonym of Boccone, Mus. v. 2. 139. t. 93, which is certainly a female, not a male, plant, though called so by the author, after the old Bauhinian fashion; and it appears to us rather to belong to the next species. The figures we have cited mostly represent three pair of leaflets, with an odd one; the Hort. Kew. describes two pair at the utmost; yet these figures must be authentic. Our plant must be what Linnæus meant by his *P. vera*, but he was imposed upon by a full-grown specimen of *P. Terebinthus*, whence his specific character of *vera* is taken. He was still more deceived by Koehler, with a branch of *Fraxinus Ornus* for *P. narbonensis*. The latter species therefore is best omitted, whatever its synonyms may belong to. We have not materials to arrange all these with any certainty.

2. *P. reticulata*. Net-leaved Pistachia Tree. Willd. Sp. Pl. v. 4. 751. Ait. n. 2. (*P. trifolia*; Linn. Sp. Pl. 1454. Pistacium mas ficulum, folio nigricante; Bocc. Mus. v. 2. 139. t. 93? Terebinthus indica major, fructu rotundo; Bauh. Hist. v. 1. par. 1. 278.)—Leaves ternate and pinnate; leaflets roundish, abrupt, somewhat pointed; tapering at the base; strongly reticulated with prominent veins. Fruit roundish-oval, obtuse.—Native of the Levant. Cultivated by Miller, as well as in the French gardens. It is generally taken for the *trifolia* of Linnæus, and perhaps ought to retain that name, but as the leaves are often pinnate, which Linnæus himself remarks, and as they mostly are so in our specimen, we submit to the above change. There seems never to be more than two pair of leaflets, and an odd one; they are all large, coriaceous, broad, rounded, and obtuse; their veins remarkably and strongly reticulated; their base more or less contracted, elongated, or wedge-shaped. When young they are downy at the margin, and elsewhere, like the foregoing. Bauhin represents the fruit as more rounded and obtuse than the common Pistachia, but equally good. His leaves however are much too pointed for our plant, and agree far better with the former; while, on the other hand, the leaves in Rauwolf's cut, cited for *P. officinarum*, to which his fruit belongs, come nearer to the *reticulata*. After all, these plants may possibly be but varieties, and we are much inclined to come to that conclusion. The following are more intelligible, and better defined by authors.

3. *P. Terebinthus*. Common Turpentine Tree. Linn. Sp. Pl. 1455. Ait. n. 3. Woodv. Med. Bot. t. 153. (Terebinthus; Matth. Valgr. v. 1. 101. Ger. Em. 1433. Bauh. Hist. v. 1. par. 1. 279. T. vulgaris; Tourn. Inst. 579. Duham. Arb. v. 2. 306. t. 87.)—Leaves pinnate; leaflets numerous, ovato-lanceolate, acute, recurved. Flowers paniced. Segments of the calyx awl-shaped, longer than the stamens.—Native of the south of Europe and north of Africa. Long known in our gardens. There is a fine female tree at Chelsea garden, near the gate, which,

for want of the male blossoms, can never perfect its fruit. The habit of this species is like the two foregoing, the trunk and branches rugged, and bent in all directions. Leaves of three to five pair of ovate-oblong entire smooth leaflets, with an odd one, all somewhat curved backwards. They are, in our climate at least, deciduous, and appear by Dr. Sibthorp's drawings to be so in Greece. Their red hue, when young, is beautiful. Flowers in large, very compound, panicles. Anthers dull yellow. Stigmas crimson. Fruit scarcely bigger than a large pea, globular, a little compressed, reticulated. Galls of the same shape are found on the leaves, and very large oblong ones, like legumes, are often produced from the young branches, as the old figures represent. The resin of this tree is the Chian or Cyprus Turpentine, generally preferred, for medical use, to what is obtained from the Fir tribe; but it is scarcely to be had without adulteration.

4. *P. Lentiscus*. Mastick Tree. Linn. Sp. Pl. 1455. Ait. n. 4. Woodv. Med. Bot. t. 152. (*Lentiscus*; Matth. Valgr. i. 99. Ger. Em. 1432. Bauh. Hist. v. 1. par. 1. 283. *L. vulgaris*; Tourn. Inst. 580. Duham. Arb. v. 1. 354. t. 130.)—Leaves abruptly pinnate; leaflets ovate-lanceolate. Flowers racemose. Segments of the calyx ovate, shorter than the stamens.—Native of the south of Europe. Less hardy than the last, and requiring the shelter of a greenhouse in our climate, being evergreen. In Italy it is very common, flowering about April; as well as in the Levant, where its resin, called mastick, is a well-known article of luxury, and different varieties of this shrub are consequently cultivated with care. It differs from every other known *Pistacia*, in having no odd leaflet, whence Tournefort made it a distinct genus; as well as in its simply racemose inflorescence, and the shortness of the calyx; but there is nothing like a reasonable generic distinction, either in fructification or habit. The wood, called *lignum lentiscinum*, has been supposed to possess some medical virtues, but its chief fame at present is in Portugal, where it serves for toothpicks. These are rather more neat than if made of deal.

P. oleosa. Lour. Cochinch. 615, is enveloped in too much uncertainty to be received without examination of specimens.

PISTACIA, in Gardening, contains plants of the exotic, deciduous, tree and shrubby evergreen kinds, of which the species cultivated are the true pistacia tree (*P. vera*); the common turpentine tree (*P. terebinthus*); and the mastick tree (*P. lentiscus*.)

With respect to the second sort, it may be remarked, that the Cyprus or Chian turpentine, which it furnishes, is procured by wounding the bark of the trunk in several places, during the month of July, leaving a space of about three inches between the wounds; from these the turpentine is received on stones, upon which it becomes so much condensed by the coldness of the night, as to admit of being scraped off with a knife, which is always done before sun-rise; in order to free it from all extraneous admixture, it is again liquefied by the sun's heat, and passed through a strainer: it is then fit for use.

Of the third sort, there is a variety which rises to the same height as the preceding; but differs from it in having a pair or two of leaflets more to each leaf, much narrower, and of a paler colour. It is a native of the country about Marseilles, &c.

Method of Culture.—The first is capable of being increased by the seeds or nuts procured from abroad, and planted in the spring, in pots filled with light kitchen-garden earth, plunging them in a moderate hot-bed; when the plants appear, a large share of air should be admitted to

them, to prevent their drawing up weak; and by degrees they should be hardened to bear the open air, to which they may be exposed from the beginning of June till autumn, when they should be placed under a hot-bed frame to screen them from the frost in winter; as while young, they are too tender to live through the winter in this climate without protection, but should always be exposed to the air in mild weather; they shed their leaves in autumn, and therefore should not have much wet in winter. In the spring, before the plants begin to shoot, they must be removed each into a separate small pot; and be plunged into a very moderate hot-bed, to forward their putting out new roots. As soon as they begin to shoot, they must be gradually hardened, and placed abroad again.

These plants may be kept in pots three or four years, till they have got strength, during which time they should be sheltered in winter; and afterwards be turned out of the pots, and planted in the full ground, some against high walls to a warm aspect, and others in a sheltered situation, where they bear the cold of our ordinary winters very well, but in severe frosts are often liable to be destroyed. The trees flower and produce fruit, but the summers are seldom warm enough to ripen the nuts.

The third sort is also capable of being increased by laying down the young branches, which, if properly managed, put out roots in one year, and may be cut off from the old plants, and be planted out into separate small pots. These must be sheltered in winter, and in summer placed abroad in a sheltered situation, and treated in the same way as other hardy kinds of green-house plants.

When raised from seeds they should be taken from trees growing in the neighbourhood of the male plants, as otherwise they will not grow. When these plants have obtained strength, some of them may be turned out of the pots, and planted against warm walls; where, if their branches are trained against them, they endure ordinary winters very well, and with a little shelter in severe winters may be preserved with safety.

They are curious and ornamental in different situations.

PISTAKETI, in Geography, a town of the principality of Georgia, in the province of Carduel; 40 miles S.S.W. of Teflis.

PISTANA, in Botany, a name by which some authors have called the *sagittaria aquatica*, or water arrow-head.

PISTATIO, among Pharmaceutical Writers, a word used to express that preparation of simples which consists in covering them with, or including them in, a paste, and sending them to a baker's oven till tender throughout. Squills are sometimes prepared thus.

PISTAZITE, in Mineralogy, named also by some writers Acaticone, Arandalite, and Thallite, is a species of the flint genus: of a pistachio-green, which passes into olive-green and blackish-green. It is found in a massive and crystallized state, under different forms: 1. In six-sided prisms, in which the lateral edges are sometimes truncated and sometimes bevelled; and the terminal edges and angles are truncated. 2. In very oblique four-sided prisms, which have a reed-like aspect; sometimes they are acuminate by four planes, and sometimes bevelled on the extremities, and the bevelling planes are set on the obtuse lateral edges. 3. In acicular crystals; internally it is shining; the fracture is foliated, sometimes narrow and parallel. The fragments are sometimes indeterminate angular, sometimes wedge-shaped and splintery. It occurs in coarse granular distinct concretions. It is translucent, which, in the crystallized varieties, passes into transparent. It is hard, easily frangible, and not particularly heavy. It is found in beds in primitive mountains in Norway, Saxony, France, and Bavaria.

PISTE, in the *Manege*, the track or tread which a horse makes upon the ground he goes over.

The word is French, and literally signifies a *track*.

The piste of a horse may be either *single* or *double*.

If the rider make him go but an ordinary gallop, in a circle, or rather square, he will make but a single piste: if he either make him gallop with his haunches in, or go terra a terra, he will make two pistes, one with the fore-part, another with the hind. And the same if the rider make him passage, or go sideways, either in a straight line, or upon a circle.

PISTEREEN, or PIASTRINE, in *Commerce*, the name given in the West Indies to the Spanish pecetas. Pisterreens are also called two-bit pieces; they pass at Jamaica for 1s. 3d. currency, and are worth 10½d. sterling. English shillings and sixpences occasionally pass here as pisterreens and bits.

PISTIA, in *Botany*, so named by Linnæus, from $\pi\sigma\tau\eta\varsigma$, a channel or watering place, because it inhabits pools and rivers.—Linn. Gen. 467. Schreb. 455. Willd. Sp. Pl. v. 3. 690. Mart. Mill. Dict. v. 3. Juss. 69. Lamarck Illustr. t. 733. (Kodda-pail; Plum. Gen. 30. t. 39.)—Class and order, *Gynandria Hexandria*, Linn. *Monadelphia Octandria*, Schreb. Willd. Nat. Ord. *Inundata*, Linn. *Hydrocharides*, Juss.

Gen. Ch. corrected by Schreber, *Cal.* none. *Cor.* of one petal, unequal, erect, permanent; tube short, closely embracing the germen; limb roundish, somewhat heart-shaped, dilated, pointed, undivided, contracted at each side, in the middle, by a lateral plait directed inwards. *Stam.* Filament round, thick, obtuse, springing almost perpendicularly from the centre of the limb of the corolla, and standing over the pistil, furrounded at the base by a membranous disk, and augmented at each side below, with a dependent fringe, the breadth of the anthers; anthers six to eight, globose, standing in a row round the margin of the filament at its summit. *Pist.* Germen superior, nearly ovate, twice as long as the tube of the corolla, attached to the back of the petal by a thickened longitudinal line, reaching to the origin of the filament; style thick, erect, shorter than the filament; stigma obtuse, somewhat peltate. *Peric.* Capsule ovate, compressed, of one cell. *Seeds* numerous, oblong, depressed, and marked with an umbilicated point at the summit, horizontally inserted into the back of the capsule, where it is attached to the corolla.

1. *P. Stratiotes*. Linn. Sp. Pl. 1365. Jacq. Amer. 234. t. 148. (Kodda-pail; Rheede Malab. v. 11. 63. t. 32. *Plantago aquatica*; Rumph. Amboin. v. 6. 177. t. 74. *Stratiotes*; Alp. Ægypt. 106. t. 108, 109. Velling. Ægypt. 44. t. 45.)—Native of Asia, Africa, and South America, in stagnant waters. Rumphius says it is found only in such as have a muddy bottom, though the plant floats entirely like a *Lemna*, sending down its long, straight, simple, pubescent roots deep into the water, but not so far as the ground. The whole herb consists of a number of broad wedge-shaped obtuse leaves, spreading in the form of a large rose, without any stem, of a coriaceous or rather spongy texture, ribbed, glaucous, with a velvet-like surface; the innermost more erect, convoluted, and downy. *Flowers* white, axillary. The plant is propagated by long lateral runners, each terminating in a bud.

PISTICCIO, in *Geography*, a town of Naples, in Basilicata; 12 miles from Turfi.

PISTILLUM, in *Botany* and *Vegetable Physiology*, the pistil of a flower, is one of those essential parts of the fructification, necessary to the production of seeds. It is either one or several, situated in the centre of the flower, within the stamens, if the latter be, as usual, in the same flower.

When in a separate one, the pistils are not always central. The idea of Linnæus, of their originating from the pith, and the stamens from the wood, is refuted by anatomical observation, as well as by more correct physiological enquiries. Each pistil consists properly of three parts; the *germen*, or rudiment of the young fruit or seed, which of course is essential; the *style*, various in length and thickness, not always present, as it merely serves to elevate the third part, the *stigma*, which, though indispensably necessary, is, in several cases, seated immediately upon the germen. See FECUNDATION of Plants, GERMEN, and, hereafter, STIGMA and STYLUS, or STYLE.

Pistils are sometimes obliterated, though more generally transformed to petals, in double flowers, as well as the stamens. In the double-blossomed cherry the pistil is actually changed to a leaf. The style in that case becomes dilated, ferrated, and assumes a deep green colour, turning to a perfect leaf, and the stigma, without much visible change, becomes the gland terminating the leaf, like what is found on the original and proper foliage. Some plants, which increase plentifully by root, are subject to have the pistils weakened and abortive, as in Mint, and *Lilium bulbiferum*; but they do not, in such cases, undergo any transformation. Many whole genera have rudiments only of pistils in some flowers, and of stamens in others, as the *Rhodiola*; such plants being in effect either dioecious, or monoecious. Still more have, intermixed with perfect flowers, whose male as well as female organs are complete, a greater or less number whose stamens only are perfect and effective, their pistils being imperfect, or entirely obliterated. Such is the nature of a great majority of tropical trees, which are therefore, in Linnæan language, polygamous, and strictly belong to the class *Polygamia*; but so much difficulty attends a close adherence in practice to this principle, in consequence of accidental variations, that it is found best to consider no plants as polygamous that have not a difference of structure in their several flowers. See POLYGAMIA.

PISTILS FIORD, in *Geography*, a bay on the N. coast of Iceland.

PISTIS, in the *Materia Medica of the Ancients*, a name given to the gum bdellium, particularly to that kind of it which was brought from Arabia, and was of a fine yellowish-white, and in small round drops, or lumps of a roundish shape, and firm consistence.

PISTOCCHI, FRANCESCO-ANTONIO, of Bologna, in *Biography*, one of the greatest itage fingers of the seventeenth century, began to flourish, both as a performer and composer, about the year 1679. He was retained some time at the court of the margrave of Brandenburg as maestro di capella; but late in life, after establishing a school of singing at Bologna, which was afterwards continued by his disciple Bernacchi, he retired to a monastery, where he ended his days.

An oratorio of his composition, which we were so fortunate as to find in Italy, called "Maria Virgine Adolorata," has more merit of expression, and elegance of melody, than any vocal music of the same century. There is no date to this composition; but by the simplicity of the style it seems to have been produced about the end of the 17th century, at which time recitative, freed from formal clothes, and in possession of all its true forms, was occasionally extremely pathetic and dramatic; and Pistocchi seems a more correct contrapuntist than the generality of opera fingers whom the demon of composition seizes at a period of their lives, when it is too late to begin, and impossible to pursue such studies effectually, without injuring the chest, and neglecting the cultivation of the voice. This oratorio has neither overture nor chorus. The interlocutors are an angel, the Virgin Mary,

Mary, Mary Magdalen, and St. John. At the termination of this oratorio, which is truly pathetic and solemn, all the degrees of the diminution of sound are used: as *piano*, *piu piano*, *pianissimo*, equivalent to the *diminuendo*, *calando*, and *smorzando*, of the present times.

Pistocchi published six cantatas, with two duets, and two airs, one to French, and one to Italian words, about the year 1699; but we have never been able to find them.

PISTOIA, anciently *Pistoria*, in *Geography*, a city of Etruria, which is an episcopal see, remarkably well built, and from the unusual wideness of the streets and solidity of its edifices, appearing both airy and magnificent. Of these buildings, the principal are the cathedral, the church called "Del Umilla," and the seminary. The dome of the first, the front, or rather the vestibule of the second, and the general disposition of the third, are much admired. Those establishments called seminaries in Italy and France, are not merely academies or schools, but colleges, where the young clergy are instructed in the peculiar duties of their profession, under the inspection of the bishop, during three years previous to the time of their receiving holy orders. Hence each diocese has its seminary, which is always in the episcopal city, and generally contiguous to the bishop's palace. In Pistoia there are two public libraries. The river Ambrone flows close to the town. The surrounding country is not only fertile and well cultivated, but unusually picturesque.

PISTOL, a little fire-arm, borne at the fiddle-bow, at the girdle, or in the pocket.

The pistol is said to have taken its name from Pistoia, a city in Italy; where, as Fauchet tells us, it was first made. Borel derives the word from *ffistula*, *pipe*; the barrel of this piece bearing some resemblance to a flute.

It is said that from harquebusses (see HARQUEBUSS) came pistole, or pistolets, with wheel-locks, the barrels of which were only one foot long, being the harquebuss in miniature. The Germans are said to have used them in France before the French; and the horsemen who received them in the time of Henry II. were called "Pistoliers." They are mentioned as early as the year 1544, under the reign of Francis I. Pistols with a simple spring, instead of the wheel formerly used, fusils and musketoons, are of modern invention; but the inventors are not known. In the year 1658, the use of wheel-locked pistols was not abolished. The wheel-lock was a little solid wheel of steel, fixed against the plate of the lock of the harquebuss or pistol; it had an axis that pierced it in its centre; at the interior end of this axis which went into the lock, a chain was fastened, which twisted round it on the wheel being turned, and bent the spring by which it was held; to bend this spring, a key was made use of, into which the exterior end of the axis

was inserted. By turning this key from left to right, the wheel was made to revolve, and by this movement a little slider of copper, which covered the pan with the priming, retired from being over it; and by the same movement the cock, armed with a flint like the cock of a fusil, was in a state to be discharged, on pulling the trigger with the finger, as in ordinary pistols; the cock then falling on the wheel, produced fire, and communicated it to the priming.

PISTOL Bay, in *Geography*, a bay on the northern extremity of Newfoundland. A late writer (1768) on the probability of a North-west passage, mentions this bay as the only remaining part of Hudson's Bay where this western communication may exist. But this has been examined; and upon the authority of captain Christopher, who failed from fort Churchill in the year 1761, for the purpose of examining Chesterfield's inlet, through which it was supposed there might be a passage to the Western ocean, the reader may be assured that there is no inlet of any consequence in all that part of the coast. Nay, he has, in an open boat, failed round the bottom of what is called Pistol bay, and instead of a passage to a western sea, found it does not run above three or four miles inland. See NORTH-WEST Passage.

PISTOLE, DOBLOON, or *Doblon*, in *Commerce*, a gold coin struck in Spain.

The pistole of exchange, as a money of account in foreign exchange (*i. e.* *dobloon de plata*), was valued at 32 reals of old plate, or 60 reals 8 maravedis vellon; but in commercial transactions within the country, it was reckoned only at 60 reals. After the year 1772, when a new coinage took place, the gold coins current in Spain have been as follow: the *dobloon* of 8 escudos, or quadruple pistole, which passes for 320 reals vellon; the *dobloon* of 4 escudos, or double pistole for 160; the *dobloon de oro*, or pistole for 80; the *escudo* for 40; and the *coronilla*, or *veinten de oro*, for 20.

In 1786, the standard of the gold was reduced to 21 carats for the different *dobloons* and their divisions, and to 20½ carats for the *coronilla*, or *veinten de oro*. The quadruple pistole, or *dobloon* of 8 escudos, coined since 1786, contains 366½ troy grains of fine gold, and is therefore worth 3*l.* 4*s.* 9½*d.* valued in English gold coin; and the subdivisions of the quadruple are in proportion: the allowance for remedy may be valued at 6*d.* in the quadruple. By the assay of the London mint, the weight of the quadruple is 17 dwt. 8 gr., and its fineness 4½ gr. worse than English standard: hence its value in English gold coin is 3*l.* 4*s.* 0½*d.* The value of gold in the Spanish coins is to that of silver as 16 to 1.

The assay, weight, &c. of the different Spanish gold coins, are as follow.

	Assay.		Weight.		Contents in pure Gold.	Value in Sterling.		
	car.	gr.	oz.	dwt. gr.		grs.	<i>L.</i>	<i>s.</i>
Quadruple pistole, or <i>dobloon</i> , coined before 1772	W.	0 1½	0	17 8½	375.4	3	6	5¼
Double pistole, before 1772, single and half in proportion	W.	0 1½	0	8 16¼	187.7	1	13	2½
Quarter pistole, or gold dollar, before 1772	W.	0 2	0	1 3	24.2	0	4	3¼
Quadruple pistole, or <i>dobloon</i> of 1772, the double and single in proportion	W.	0 2¼	0	17 8½	372.	3	5	10
Half pistole, or <i>escudo de oro</i> of 1772	W.	0 2½	0	2 4	46.4	0	8	2½
Quarter pistole, or golden dollar of 1772	W.	0 3	0	1 3	24.	0	4	3
Quadruple pistole of 1801	W.	1 1	0	17 9	360.6	3	3	10
Double pistole of 1801	W.	1 1	0	8 16½	180.3	1	11	11
Pistole, or <i>dobloon</i> of 1801	W.	1 1	0	4 8¼	90.1	0	15	11½
Coronilla, or golden dollar of 1801	W.	1 2½	0	1 3	23.	0	4	1

The impressions on the gold coins of Spain are as follow : on the doubloon or pistole is the head of the reigning king, with name and title ; thus, CAROL. III. D. G. HISP. ET IND. REX, that is, Charles III., by the grace of God, king of Spain and the Indies : reverse, arms of Spain, with the collar of the golden fleece ; legend, in 1740, INITIUM SAPIENTIAE TIMOR DOMINI, the fear of the Lord is the beginning of wisdom ; in 1762, NOMINA MAGNA SEQUOR, I follow great names ; in 1763, IN UTROQUE FELIX AUSPICE DEO, happy in both under the divine auspices : there is also at the bottom a letter to mark the place where the piece was coined ; thus M, with a crown over it, signifies " Madrid ;" M with an O over it, " Mexico : " there are also one or two other letters, which vary, being the initials of the moneyer's name. The double, quadruple, and half pistoles bear the same impressions ; but in modern coins, the half pistole is marked " 1 s," 1 scudo, or gold crown ; the single pistole " 2 s," and the others in proportion. The pieces coined between 1700 and 1723 bear no head, but have the arms, and the king's name with DEI GRA. ; on the reverse, a cross surrounded with different ornaments ; legend, HISPANIARUM REX. Those coined before that period are not round, but of an irregular shape, and their impressions are very imperfect.

The doubloon of 1809, coined by Joseph Bonaparte, bears on the front his head, with the legend, JOSEPH NAP. D. GR. HISP. ET IND. R. I. E. Joseph Napoleon, by the grace of God, king of Spain and the Indies : reverse, arms of Spain with a crown ; legend, IN UTROQUE FELIX DEO AUSPICE, as before. The divisions of the doubloon bear the same impressions.

The coronilla, or golden dollar, bears the same impressions as the doubloon, except with regard to the legends. Those of an ancient date have on one side the king's name, with D. G., and on the reverse HISPANIARUM REX ; whilst those coined in 1786, &c. bear the name and title on the same side ; and there is no inscription on the reverse except initials, as in the doubloon.

In Germany, under the name of pistoles are included the Saxon Augst. d'ors, Prussian Frederick d'ors, Brunswick Carl d'ors, Hanoverian George d'ors, Danish Holstein Christian d'ors, and the pistoles of Hesse, the Palatinate, Hildesheim, and Mecklenburg ; all reckoned at five rix-dollars current ; 35 pieces of each of these sorts of money are to weigh a Cologne mark, and the gold to be $21\frac{3}{4}$ carats fine ; so that $38\frac{1}{4}$ pieces contain a Cologne mark of fine silver. An allowance is, however, generally made for a deficiency in weight and fineness, and they are current, in most places, as long as 35 pieces weigh a Cologne mark of gold, $21\frac{1}{4}$ carats fine : they are then called " passier pistoles." The assay of the George d'or of Hanover is W. o car. $1\frac{1}{4}$ gr. ; weight, o oz. 4 dwt. $6\frac{1}{2}$ gr. ; the contents in pure gold 92.6 gr. ; and value in sterling, 16s. $4\frac{1}{2}$ d. The assay of Hesse-Cassel pistole is W. o car. $2\frac{1}{2}$ gr. ; weight, o oz. 4 dwt. $7\frac{1}{4}$ gr. ; contents in pure gold, 92 ; value in sterling, 16s. $3\frac{1}{2}$ d. Assay of Manheim pistole W. o car. $1\frac{1}{2}$ gr. ; weight, o oz. 4 dwt. $6\frac{1}{2}$ gr. ; contents in pure gold, 92.5 ; value in sterling, 16s. $4\frac{1}{2}$ d. The George d'or of Hanover bears on the front the king's arms ; legend, GEORG. II. D. G. M. B. F. ET H. REX. P. D. ; reverse, V THALER (5 rix-dollars of account), and under this the date ; legend, BRUNS. ET LUN. DUX S. R. L. A. T. H. ET ELECT. The pistole of Hesse-Cassel bears the head of the reigning prince, with his name and titles, thus : WILHELMUS IX. D. G. HESS. LANDG. HAN. COM., William IX. by the grace of God, landgrave of Hesse, count of Hanau ; reverse, a star, and within it, the legend, VIRTUTE ET FIDELITATE, by courage and fidelity ; in the centre, a lion. Other pis-

toles, coined in 1794, &c. bear on the reverse a lion at rest with standards and military trophies, and over this 5 THALER.

The pistole of Manheim bears the head of the reigning prince, with name and title, thus : CAR. THE. C. P. S. R. I. A. T. ET EL. that is, Charles Theodore, count palatine, high steward and elector of the holy Roman empire ; reverse a crown, formed by four crowns, and four cyphers of the letters C. T. ; legend, DOMINUS REGIT ME, God directs me.

In various parts of Italy, the pistole is known under the name of doppia.

In Geneva the gold coins are the old pistole of 11 livres 10 fols ; and the new pistole coined since 1752, worth 10 livres current, or 35 florins, with double and triple pistoles in proportion. The assay of the old pistole of Geneva is W. o car. 2 gr. ; weight, o oz. 4 dwt. $7\frac{3}{4}$ gr. ; contents in pure gold, 92.5 gr. ; value in sterling, 16s. $4\frac{1}{2}$ d. The assay of the new pistole is W. o car. $0\frac{1}{2}$ gr. ; weight, o oz. 3 dwt. $15\frac{3}{4}$ gr. ; contents in pure gold, 80 ; value in sterling, 14s. 2d.

The assay of the pistole of the Helvetic republic of 1800 is W. o car. $1\frac{1}{2}$ gr. ; weight, o oz. 4 dwt. $21\frac{1}{2}$ gr. ; contents in pure gold, 106 gr. ; value in sterling, 18s. 9d. The assay of the pistole of Lucerne is W. o car. $1\frac{1}{2}$ gr. ; weight, o oz. 4 dwt. $21\frac{1}{2}$ gr. ; contents in pure gold, 106 gr. ; value in sterling, 18s. 9d. The assay of the pistole of Soleure is W. o car. $1\frac{3}{4}$ gr. ; weight, o oz. 4 dwt. 22 gr. ; contents in pure gold, 106.8 gr. ; value in sterling, 18s. $10\frac{3}{4}$ d. The impressions on the pistole of the Helvetic republic are a soldier carrying a standard ; legend, HELVETISCHE REPUBLIC, Helvetic republic ; reverse, a crown of oak, containing 16 FRANKEN : the double pistole is marked 32 FRANKEN. The pistole of Lucerne bears the arms of the city, with the legend, REPUBLICA LUCERNENSIS ; reverse, a wreath of laurel, containing 12 M 2. GL., and under this the date. The double pistole is marked 24. The pistole of Soleure bears a warrior carrying a standard ; legend, s. URSUS MARTYR ; reverse, arms of the city ; legend, REPUBLICA SOLODORENSIS, republic of Soleure. The double and half pistoles bear the same impressions.

The assay of the pistole, or doppia, of Piedmont, of 1741 to 1785, is W. o car. $1\frac{3}{4}$ gr. ; weight, o oz. 6 dwt. $4\frac{1}{2}$ gr. ; contents in pure gold, 134.2 gr. ; value in sterling, 1l. 3s. 9d. The assay of the pistole coined since 1785 (half, &c. in proportion) W. o car. $1\frac{3}{4}$ gr. ; weight, o oz. 5 dwt. 20 gr. ; contents in pure gold, 127.8 gr. ; value in sterling, 1l. 2s. $7\frac{1}{2}$ d. The assay of the doppia or pistole of Genoa, (the pieces of of 2, 4, and 5 pistoles in proportion) is W. o car. $1\frac{1}{2}$ gr. ; weight, o oz. 4 dwt. $7\frac{1}{2}$ gr. ; contents in pure gold, 93.4 gr. ; value in sterling, 16s. $6\frac{1}{4}$ d. For other particulars relating to the pistole, both as a money of account and as a coin, we refer to Kelly's Universal Cambist.

N.B. W. every where denotes worse than the English standard.

PISTOLOCHIA, in Botany, a name used by some authors for the plant of which the Virginian snake-root of the shops is the root.

PISTON, a part or member in several machines, particularly pumps, air-pumps, syringes, &c. called also the embolus, and popularly the sucker.

The piston of a pump is a short cylinder of metal, fixed exactly to the cavity of the barrel, or body ; and which, being worked up and down alternately therein, raises the water ; and when raised, presses it again, so as to make it force up a valve with which it is furnished, and so escape through the nose of the pump.

There are two sorts of pistons used in pumps ; the one with

with a valve, which is called a bucket; and the other without a valve, which is called a forcer. See PUMP.

The pistons of air-pumps, syringes, &c. see described under AIR-PUMP and SYRINGE.

PISTORIA, in *Ancient Geography*. See PISTOIA.

PISTRINA, in *Geography*, a town of Servia; 48 miles S.W. of Nissa, and 100 miles E. of Ragusa.

PISTRITZER, a river of Saxony, which runs into the Elbe, near Wittemberg.

PISTYRUS, or PISSIRUS, in *Ancient Geography*, a town in the western part of Thrace, near Meſtras, in the territory of which, according to Herodotus, was a lake thirty stadia in circuit.

PISUERGA, in *Geography*, a river of Spain, which springs in the N. part of Old Castile, and runs into the Duero; 10 miles S.W. of Valladolid.

PISUM, in *Botany*, the Pea, an ancient name, whose origin is lost in its antiquity. Some of the learned are content to deduce it from the Greek *πισω*, which means the same thing, and which others derive from *πισσω*, to stamp, or bruise, because it was customary to take off the skin by such means. De Theis thinks the Celtic *pis*, which is *pisen* in the plural, (he by mistake says singular,) is the common root of this word in all languages. Hence the Anglo-Saxon *pisa*; the English *pea*, *pease*, and still in obsolete Norfolk *peasen*; the French *pois*, and for a pea-field, in old language, *pefiere*; the Italian *piso*; the Welsh *pus*; all synonymous. Linn. Gen. Pl. 374. Schreb. 496. Willd. Sp. Pl. v. 3. 1070. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 760. Ait. Hort. Kew. v. 4. 302. Juss. 360. Tourn. t. 215. Lamarck Illustr. t. 633. Gært. t. 152. (Ochrus; Tourn. t. 219, 220.)—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, five-cleft, acute, permanent; the two upper segments broadest. *Cor.* papilionaceous. Standard very broad, inversely heart-shaped, reflexed, emarginate with a little point. Wings two, roundish, converging, shorter than the standard. Keel compressed, half crescent-shaped, shorter than the wings. *Stam.* Filaments in two distinct sets; one simple, uppermost; and nine awl-shaped, united more than half-way into a cylinder, split along its upper side; anthers roundish. *Pist.* Germen oblong, compressed; style ascending, triangular, membranous, keeled, its sides bent outwards; stigma united with the upper angle, oblong, villous. *Peric.* Legume large, long, roundish, or compressed towards the base, terminating in a point directed upwards, of one cell and two valves. *Seeds* several, globose.

Obf. *Ochrus* of Tournefort has an oblong scar to the seed; *Pisum* of the same author has a roundish scar.

Eff. Ch. Style triangular, keeled and downy at the upper side. Two upper segments of the calyx broadest. Stamens in distinct sets.

1. *P. sativum*. Common Pea. Linn. Sp. Pl. 1026. Willd. n. 1. Ait. n. 1. (Pisum; Riv. Tetrap. Irr. t. 36. Camer. Epit. 213. P. majus; Matth. Valgr. v. 1. 389. Ger. Em. 1219.)—Footstalks cylindrical. Stipulas rounded and crenate at the base. Stalks bearing several flowers.—Native of the south of Europe. Dr. Sibthorp found it, apparently wild, in various parts of Greece. The root is annual. Stem branched, leafy, smooth, climbing by means of tendrils, and various in height. Leaves alternate, pinnate, of about six, elliptical, nearly opposite, mostly entire leaflets, on a common footstalk, ending in a compound tendril. Stipulas in pairs at the insertion of the footstalk, much larger than the leaflets; rounded, lying over each other, and

copiously crenate, at the base. Stalks axillary, solitary, bearing two or more large, pearly-white, inodorous flowers. Upper segments of the calyx broader, hardly shorter, than the rest; all of them ovate, acute. Legume about a finger's length, smooth.

Of this valuable plant botanists have distinguished several varieties, and gardeners several more. Among the latter are the Marrowfat, the Rounceval, the Hotspur, &c. Among the former are the Sickie Pea of Miller, *Pisum filiqua curva*; Rivin. Tetrap. Irr. t. 37; the Dwarf Pea, *P. nanum* of the same author, t. 38. f. 2; the Sugar Pea, *P. cortice eduli*; Tourn. Inst. 394; and the Rose, Crown, or Topknot Pea, *P. umbellatum*; Mill. Dict. ed. 8. n. 3. Ger. Em. 1220. *P. comosum*; Riv. Tetrap. Irr. t. 38. f. 1. These two last, (the Sugar and the Crown Peas,) agree in the remarkable property of having no hard rigid lining to the legume, so that their pods may be boiled and eaten entire, having moreover a very sweet and agreeable flavour. The flowers of the Crown Pea, at least, have elegant rose-coloured wings, and their stalks grow many together about the top of the stem, rendering the plant very ornamental, and the crop abundant. We have often been tempted to consider this as a distinct species. The notches of the stipulas are, as Miller remarks, about four, being much fewer than in the Common Pea; but we can find no sufficiently clear and permanent specific mark.

2. *P. arvense*. Field, or Grey Pea. Linn. Sp. Pl. 1027. Willd. n. 2. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 687, unpublished. (*Pisū pulchra* species, folio anguloso; Bauh. Hist. v. 2. 297. Morif. v. 2. sect. 2. t. 1. f. 4.)—Leaflets four on a stalk. Stipulas strongly crenate. Stalks single-flowered.—Native of fields in several parts of Europe. Dr. Sibthorp found it near Constantinople; and it is often in some degree naturalized with us. This seems scarcely more than a variety, or perhaps the true original state, of the first species, differing in having rather fewer leaflets, which are more frequently ferrated; solitary purplish flowers, whose wings are of a violet purple; and rather more strongly crenate, often angular, stipulas.

3. *P. fulvum*. Tawny-flowered Pea. Sm. Prodr. Fl. Græc. Sibth. v. 2. 62. Fl. Græc. t. 688, unpublished.—Footstalks cylindrical. Stipulas rounded at the base, sharply toothed. Stalks two-flowered. Legumes shortened.—Gathered by Dr. Sibthorp in Asia minor, probably near Smyrna. This is smaller than the preceding. Leaflets two or four, ferrated. Base of the stipulas, rounded, dilated, very sharply and copiously toothed. Flowers elegant; their standard salmon-coloured, veined with crimson or scarlet; wings of an orange hue; keel of a tawny yellow. Legume scarcely more than an inch long, half-elliptical. Seeds from three to five.

4. *P. maritimum*. Sea Pea. Linn. Sp. Pl. 1027. Willd. n. 3. Ait. n. 3. Sm. Spicil. 8. t. 9. Engl. Bot. t. 1046. Fl. Dan. t. 338.—Footstalks slightly flattened above. Stem angular. Stipulas arrow-shaped. Stalks many-flowered.—Native of the stony sea beach in the north of Europe, and according to Linnæus and Pursh, of North America also. It was first noticed in England between Aldburgh and Orford, Suffolk, when a year of scarcity caused it to attract the observation of the distressed peasantry, who derived great relief from these wild peas, as Caius, Gerarde, and others relate; see Ger. Em. 1250. The long deep perennial roots were also found to be sweet and eatable. The stems are short, procumbent, thickly clothed with greyish glaucous leaves, each composed of six or eight oval, entire, generally alternate leaflets, and ending in a divided tendril. Flowers handsome, variegated with purple and blue, many

PISUM.

together on longish axillary stalks. *Legumes* linear-oblong; their young *seeds* about as good as the Grey Pea.

5. *P. Ochrus*. Wing Pea. Linn. Sp. Pl. 1027. Willd. n. 4. Ait. n. 4. Sm. Fl. Græc. Sibth. t. 689. (*Ochrus* five *Ervilia*; Ger. Em. 1249. *Aracus niger*; Matth. Valgr. v. 1. 384.) Leaflets two, on winged decurrent footstalks. Flower-stalks single-flowered. — Native of Italy, Spain and the Levant. It was cultivated in the English gardens in Gerarde's time, being a hardy annual, flowering in June and July. The very large broad wings of the *foot-stalks* mark it sufficiently. Each lobe of these bears, at the summit, an oval glaucous *leaflet*, sometimes more, and the middle part ends in a many-branched tendril, winged at the base. *Flower-stalks* axillary, solitary, much shorter than the footstalks, single-flowered. *Corolla* pale buff. *Legume* an inch and an half long, channelled and winged at the back. Of the quality of the peas we have no information.

PISUM, in *Gardening*, comprises plants of the hardy herbaceous kinds, of which the species cultivated are; the common pea (*P. sativum*); the sea pea (*P. maritimum*); and the yellow-flowered pea (*P. ochrus*).

Of the first fort there are two principal varieties, the white and grey; and several sub-varieties, the principal of which are:

Early Kinds.—The early golden hotspur; early Charlton hotspur; Nichols's early golden hotspur; the early Charlton; the Reading hotspur; Malters's hotspur; Ormrod's hotspur; early dwarf hotspur; Leadman's dwarf; fan Spanish dwarf; early dwarf frame pea; pearl pea; cluster pea; royal green pea; Essex hotspur; the dwarf pea; the fugar pea.

Late Kinds.—Spanish morotto; nonpareil; fugar dwarf; sickle pea; marrowfat; dwarf marrowfat; rose or crown pea; rounceval pea; grey pea; large grey pea; crooked grey pea; long-bearing pea; green field pea; white field pea; pig pea.

Many of the first sub-varieties are very early, and being low growers, require sticks of three or four feet only in height, and often not so much. New varieties of these are raised almost every year, which, because they differ in some slight particular, are sold at an advanced price, and have frequently the names of the persons who raised them, or the place where they first grew. These varieties are not permanent, and without the greatest care will soon degenerate.

Method of Culture in the open Ground.—All the sorts of the first kind are raised from seed sown annually; and as those of one sowing continue but a short time in bearing, several sowings are requisite each season, to continue successions for the table all summer; each sowing to remain where sown, choosing a warm dry border, &c. for the earliest crops; and for the succeeding ones, any of the common quarters, in a free exposure, distant from the shade of trees, &c., but open to the sun.

For the late crops the more moist parts are the best.

The general season for sowing is any time in open weather, from the latter end of October, or in November, until May or June.

But in order to have green peas as early as possible, recourse must be had to the assistance of hot-beds, by the aid of which they are obtained in March and April, and continued till the coming in of the natural ground crops, in the latter end of May or beginning of the following month.

The early and first general Crops.—Towards the latter end of October, in November or December, as the weather may be convenient, the earliest crops should be put into the ground. In warm soils and situations it is always advisable to sow a few in the two former months; but in general, and

especially in open exposed grounds, November and December is time enough to begin the principal sowings. For this purpose the earliest Charlton or golden hotspurs are the most proper.

And in order for their reception a warm south border, or some other dry, sheltered, sunny situation should be dug over and prepared; when, in a dry day, drills should be drawn by a line, ranging south and north, to enjoy the greater advantage of the sun's influence, making them an inch and a half deep, and two feet and a half at least asunder; but if designed for sticks, three feet and a half will be a more proper distance. Then the seed should be scattered in evenly along the middle of each drill, rather thickish, as they are liable to accidents from vermin and the season, covering them in regularly with the earth either with a rake or hoe, being careful that they are all equally covered the depth of the drills; and then with a rake lightly trim the surface smooth; which finishes the work.

The peas begin to germinate in a fortnight, if mild weather, and come up in three weeks or a month, but seldom in less time at this season; when the plants are to be managed as directed below.

Another sowing should be performed in three weeks or a month after this; or when the first was sown in October or early in the following month, it is better to repeat the sowing in a fortnight or three weeks, for fear the first should fail; and after this continue sowing once in three weeks or a month all winter in mild weather. But towards spring a principal crop of the Reading and other large hotspurs should be sown; and as the season advances, the sowings be made in more open exposures, and more in quantity than the early ones; and as the spring draws on, the sowings should also be repeated oftener; as from the close of the year till the beginning of April, they should be once in three weeks; and from that time till May once a fortnight, especially as the warm weather increases.

The winter and early spring sowings differ materially in the time they require to germinate: those sown any time in winter are sometimes three weeks or near a month before they appear, while those sown towards spring come up much sooner, in the later spring sowings, often in a very short time.

In the later of the above sowings, some of the dwarf sorts may be introduced; as Leadman's dwarf, both for middle and late crops.

As the plants of each sowing come up, and are advanced two or three inches in height, it is proper to begin the first culture by drawing a little earth with a hoe, or small rake, lightly up to their stems on each side of the different rows to strengthen and forward their growth, repeating the earthing once or twice at proper intervals, as occasion may require, and at the same time cutting up and clearing away all weeds; and when the crops are six or eight inches in height, those designed for support should be sticked.

As the earliest crops are often in danger from the severity of frosts, it is proper, when they are about an inch and a half high, to draw a little fine earth lightly up to their stems in a dry day; it will also be of much advantage to give occasional protection to such crops in severe weather, by covering them lightly with long, light, dry litter, of the strawy kind, or by mats; which, where there is but a moderate quantity in warm borders, may be more easily effected; but this need only be practised in very severe frosts. They must however be carefully uncovered every fine day in temperate weather; and the moment the frost disappears the covering be entirely removed; as they must by no means be kept too close, which would draw them up weak and tender.

When

When in blossom, if the weather should prove dry and warm, a few good waterings in the mornings will be beneficial; and when the blossoming plants are advanced a considerable height, if they are then topped, it will promote their podding and coming to perfection.

As to the succeeding crops of the different kinds, all they require is hoeing up the earth to their stems occasionally, and cutting up all weeds when they appear; those designed for support being always staked as soon as they are half a foot high, or a little more, before they begin to fall down on their sides, providing sticks about four or five feet long, and placing one range to each row principally on the fourth or most sunny side of the rows, as the plants naturally incline towards the sun, and of course more readily attach themselves to the sticks.

In the culture of the larger kinds, for successional general crops, such as the marrowfats, Spanish morottos, &c. they may be begun sowing in January, the dwarf marrowfats first; but the three following months are the most proper for the general crops of all the large kinds; a free exposure in the most open quarters being made use of, drawing drills by line, about an inch and a half or two inches deep, and not less than a yard asunder, and when staked, four feet, and for the largest sorts four feet and a half or five feet, in single or double rows.

In these cases the seed should be sown thinly along the middle of each drill, drawing the earth evenly over them with the rake, hoe, or feet, covering them equally the depth of the drills, and raking the surface smooth; these sowings being repeated once a fortnight or three weeks; and as the spring advances once a fortnight, especially from the beginning of April until the end of the following month. Afterwards a few may be sown every ten or twelve days. Late sowings are, however, seldom very fruitful, being often attacked with the mildew; but it is proper to endeavour to have some as long in the season as possible.

When these different crops are come up about three inches high, they should have earth laid up to them on each side of the rows, cutting down all weeds, and repeating the hoeings occasionally according as the growth of weeds may require; and when they are half a foot, or eight or ten inches high, they should have the sticks placed to them; which for these large sorts require sticks six or seven feet high at least, placing them on the sunny side of the rows, as directed above.

For late crops, any of the sorts, either hotspurs or larger kinds, may be continued sowing all May and until the middle or latter end of June; likewise some of the dwarf sorts at a later period for late production. It may be proper to sow larger portions of Rouncivals for the latest crops, on account of their being rather the hardiest to struggle with the summer's heat and drought, and thereby most to be depended on for a late production.

For these crops some of the moistest ground should be chosen; and if the weather should prove very dry and hot, it will be of importance to soak the seed in soft water six or eight hours previous to sowing; or the drills may be well watered after it has been done; either of which will promote their rising expeditiously and more regularly.

It may be observed, in respect to the times of sowing, that it is a good rule, in the different sorts, as soon as one crop appears fairly above ground, to sow another to succeed it of the same kind, so as to have a regular succession of crops following one another in bearing; and if a crop of marrowfats, &c., and another of hotspurs, be sown on the same day, the hotspurs will come into bearing a fortnight

the soonest, and the marrowfats will arrive to a bearing state about the time the others are going out, just in due time to succeed them; which should be attended to in order to have these sorts form a regular succession to each other.

In gathering the crops, both hands ought always to be employed; one to hold the peduncle or footstalk of the fruit, while the other pulls the pods; otherwise the stem or main stalk of the plant, being slender, fragile, and weak, is liable to be broken and destroyed; and the gatherings should always be regularly performed according as the pods fill, never letting them stand to grow old, as they are in the greatest perfection for eating while green, and the plants continue longer in bearing. Crops of peas continue only about a fortnight in full bearing, during which time they furnish a plentiful gathering of pods in their perfection; though in moist showery weather they sometimes continue shooting and flowering three or four weeks; but the produce after the first fortnight is generally inferior both in quantity and quality.

As soon as the crops are past bearing, all the sticks should be taken up and tied in bundles, being set upright in any dry corner for future use.

Method of Culture in Hot-Beds.—In order to have green pease as early in the year as possible, recourse must be had to the assistance of hot-beds; and the proper sorts for this purpose are the early dwarf kinds, which by this means may be brought into bearing in March, or the following month.

In this intention, it is rather the best mode to raise the plants first in the natural ground, by sowing in October, or the following month, giving occasional protection from frost; and when one or two inches high, to transplant them into the hot-bed, in January, or the beginning of the following month: as by this practice the luxuriant growth of the plants is so checked by the removal, that they shoot more moderately, and thereby blossom and bear sooner, and more abundantly.

The sowings should be performed in a warm, dry, south border, or in some similar dry sheltered part of light good earth, in a bed of proper dimensions, to have the protection of a frame, &c. in severe weather; sowing them in drills about a foot asunder, in the manner as for the common crops. When they are come up, and advanced a little in growth, in a dry day, some fine earth should be drawn up to their stems, giving suitable protection in bad weather.

But they may be sown on a moderate hot-bed in December, or January, under frames, &c.; and when the plants are up, plenty of free air should be admitted every temperate day, and be defended in the nights from frost, snow, and cutting cold; or, some may be sown in large pots, and be placed in a hot-house, &c. to bring up the plants quickly, for transplanting into the intended hot-bed in January. And they may be sown at once in a hot-bed, at the above periods, to remain for bearing; but it is generally more eligible to have the plants previously raised an inch or two in height, either by early sowing in the full ground, or forwarded under frames, or in a hot-bed, &c. as above, for transplanting into a fresh-made hot-bed for bearing.

In either of the above methods of raising the plants for transplanting, when advanced from one to two inches in growth, or little more, they are proper for planting out into the hot-bed to remain for fruiting.

In mild weather, towards the middle or latter end of January, or the beginning of the following month at furthest, a hot-bed for one or more of the largest three-light frames and glasses should be prepared, which may be either of dung

or tan: the latter, where it can be obtained easily at a moderate expence, is considerably the best for this purpose. It should be made two feet and a half, or a yard thick, and covered with frames and lights; and when in a moderate temperature, the earth be put on for the reception of the plants. Any light, good, dry earth may be employed, which should be laid eight or ten inches thick all over the bed; then in a dry mild day, the plants may be taken up, raising them with their roots as entire as possible, with what earth will readily hang about the fibres; and after drawing small drills in the earth of the hot-bed, from the back to the front of the frame, a foot and a half asunder, and about an inch deep, the plants should be put in the drills, not more than an inch apart, covering in the earth close to their roots and stems, and giving a very light watering, just to settle the earth; after which the lights should be put on, being careful to raise them occasionally at the upper end, to give vent to the steam, &c. And at first planting out, when in sunny weather, if the plants should flag, a moderate shade should be given in the middle of the day, till the plants have taken root, and established themselves.

After this, fresh air must be admitted to the plants daily, in fine weather, to strengthen them, by tilting the upper end of the lights, according to the temperature of the bed and outward air; keeping them close in cold nights, and covering also with mats. Occasional moderate waterings should likewise be given in fine days; and, as the plants advance in growth, a little earth be drawn up to their stems once or twice; repeating the moderate refreshments of water frequently, as the warm season advances; which may be given more freely when the plants are in bloom. And according to the advanced growth of the plants, and increased warmth of the weather, a larger share of fresh air in proportion should be given; and when they are in blossom, if the sun at any time appears too violent for them through the glasses, it is advisable to give a very slight shade an hour or two in the heat of sunny days: likewise, when in full blossom, and fruiting, to admit plenty of free air; even sometimes, in fine days, shoving the glasses entirely off; also still continuing the waterings more abundantly during the time of setting and growth of the pods, and indulging them with the benefit of warm showers of rain. In this way, the plants may be brought to bearing in March or April; and by a succession of two crops, in hot-beds made at three or four weeks' interval, and managed as above, a supply be continued till the natural ground crops come into bearing in May.

Where there is the convenience of fruit forcing-houses, hot-walls, &c. a few of the earliest kinds, either previously raised in young plants an inch or two in growth, as in the hot-bed culture, or, in default of it, the seed sown; and which being in pots, are placed in these departments: or, where there are internal borders of earth, some young plants may be placed therein. The internal moderate heat of the above departments, effected either by bark-beds, &c. or fire, or both occasionally, in a requisite degree for forcing the fruit-trees to early production, forwards them also, so as to have some for gathering in the most early season, in a small proportion.

Method of Culture in the Field.—Where designed to raise crops, in order to gather the produce green and young, for the supply of markets, November, or rather December, is soon enough to begin the first sowings, especially in open exposed grounds; a dry light soil being chosen for the more forward sowings. As to the sorts, any of the hotspurs may be used for the forward crops; and for a general crop,

the Reading hotspur is excellent; and after that sort, the Masters's and Ormrod's, &c.; but of the large kinds, the marrowfats and Spanish morattoes should be chosen for the main crops.

The ground for their reception must be prepared by proper ploughing and harrowing; drills are then to be drawn with a hoe crossways the lands, or with a drill-plough lengthways, two feet at least, or two and a half asunder for the early, and three for the larger sorts. As no sticks are intended for these large field crops, having sown the seed, it should be covered in either with the hoe, rake, or harrow; but the hoe or rake will cover them more evenly, and almost as expeditiously. When they come up, they must be kept clean from weeds, by broad-hoeing; but this is sometimes performed in fields by horse-hoeing, for the sake of expedition; which, having hoes fixed in a sort of plough horizontally, is drawn by a horse between the rows, a man holding the plough-shafts to guide it. But as this can only cut down the weeds, a common drawing hand-hoe must be used to earth up the plants: though this is often disregarded in the field-culture, it, however, proves very beneficial to the crops.

In these cases, the rows should be laid down so as to face the sun as much as possible.

Method of saving Seed.—In order to save seed, some of each sort should be suffered to stand entirely for that purpose, or some sown of each purposely in different parts; and the whole produce suffered to remain and ripen for seed.

In the latter mode, they should be sown in February, in some open ground, in rows two or three feet asunder, no sticks being required; and, when the plants come up, be kept clean from weeds by hoeing, the earth being laid up to their stems once or twice. When they are in bloom, they should be examined row by row, to see if there be any degenerate sort, which, when present, must be pulled out; or if any improved variety be discovered, to mark it; which is the only method to preserve both the purity of the known sorts, and to procure new varieties. For example: if amongst the hotspurs any large sorts appear, they should be removed directly; also any hotspurs, &c. from amongst the large kinds; and different sorts of any of these from each other. And if any new sort discovers itself, either by flowering earlier than all the rest, or possessing some other singularity, or noticeable merit for culture, it should be carefully marked; the seed being saved separate, to sow separately for furnishing a proper increase.

According as the seeds of the different sorts ripen in July and August, which is discoverable by the pods changing brown, and the seed becoming a little hard, the haulm should be cut or pulled up in dry weather, and exposed in heaps to the sun, turning them every day; and when the seed is become perfectly dry and hard, it may either be threshed out directly, or stacked up in a dry situation, till another opportunity: but when threshed, each sort must be kept separate, and, when properly cleaned, be put up in sacks, with the name of each upon them.

PIT and Gallows, in our *Ancient Customs*. See *FURSA* and *FOSSA*.

PITS, Brine, the name given by the people of Worcester-shire and Cheshire, to the wells or pits affording the salt water, out of which they extract the salt.

These waters, though they all contain salt, yet have other things also in them, and these not in small quantity. They all contain a very large proportion of stony matter: this is common to the whole set, but particular substances beside
this

this are found in the particular pits. At Northwich, in Cheshire, there are four pits, the water of which stinks very strongly of sulphur, and contains so much vitriol, that it will turn black like ink, with a decoction of galls: yet this is boiled into a very fine and pure kind of salt, common at our tables under the name of basket-salt, and having no such properties.

There is a vast quantity of stony matter precipitated from these pans of brine, in the boiling of them to salt: this is partly saved in small pans set at the side of the boiler, and partly precipitates to the bottom of the pan, where it forms a crust like that at the bottom and sides of our tea-kettles, which the workmen find it necessary to remove every week; but there is no vitriol or sulphur separated. Phil. Transf. N^o 150.

In the country near where these brine-pits are, the instruments used in boring often bring up fine and hard salt; so that they give proofs of there being rocks of salt in many places.

All along the river Weaver, on each side, the earth affords brine wherever it is opened; but all these are not fit for boiling, many of the pits affording a brine too weak to be worked to any advantage. The very strongest pits sometimes also become at once too weak: this is owing to the irruption of fresh springs into them, and sometimes the river itself makes its way into them, and overflows them with such a quantity of fresh water, that they are utterly spoiled. The brine-pits at Weston, near Stafford, afford a brine that stinks like rotten eggs: this turns instantly to ink with galls, and purges and vomits violently, if taken even in a small quantity. This, in boiling, deposits a white flaky sand, or stony matter, without smell or taste, and the salt is pure and fine.

The pit at Droitwich, in Worcestershire, affords no sand in the boiling, nor any the least sediment of the stony matter at the bottom of the pan, and the salt is the purest of all the others; and by the people of the country it is esteemed the most wholesome, because of its being without the sand.

This and the other pits hereabout, all have the smell of rotten eggs, especially after a little rest, as on the Monday morning after the Sunday's rest. If meat be put to pickle in the brine of these pits, instead of being preserved, it will stink in twenty-four hours, sometimes in twelve, yet they yield the best salt of any inland pits in the world.

The sulphur spaws of Yorkshire, which are very numerous in different parts of the county, all stink violently of rotten eggs; but if well drawn and worked, they would prove as offensive as the rest, and only so many weaker or stronger brine pits; and the smell is no other than that of the Cheshire and Staffordshire brine, when it has been left some time at rest. It is remarkable, that though the stony matter is deposited in such vast plenty by the waters of all our salt springs, it is not found in any abundance in those places where salt is made out of sea-sand, as in Lancashire, and some other places; so that it is much more than the natural quantity of spar contained in water that is thus deposited; and indeed it appears from trial, that the brine of our salt springs, in general, contains more than twenty times the quantity of spar that common water does.

This stony matter separates itself from the water before the salt does, and thus it appears in many other waters impregnated with mineral particles. The vitriolic waters all contain ochre and salt, and in all these the ochre separates itself first in the boiling, and then the vitriol; and the stony matter precipitated from common salt springs affords, on an

analysis, the salt called *nirum calcareum*, in considerable abundance. Phil. Transf. N^o 156. See SALT.

PITS, *Forcing*, in *Gardening*, such as are formed and constructed on somewhat similar principles to those in hot-houses, stoves, &c., and which are found of very great use and advantage in raising crops of culinary exotics, as cucumbers, and many other sorts;—in forcing common vegetables, as asparagus;—in raising young exotics, as pines and other plants;—or in producing grapes. For these general purposes, pits have been constructed with one single fire, which are capable of producing four different temperatures of heat at the same time. They are, consequently, able to force all kinds of common vegetables, and capable of growing vines, pines, and melons, each in their proper climate, with one fire, and little trouble or expence. See *HORHOUSE* and *STOVE*.

PIT-Coal. See *COAL*.

Vegetables have been considered as the materials for the formation of pit-coal; but M. Chaptal observes, that a few forests, being buried in the earth, are not sufficient to form the mountains of coal which exist in its bowels. He thinks some provision, greater and more proportioned to the effect, is requisite, and this he finds only in the prodigious quantity of vegetables which grows in the seas, and which is still increased by the immense mass of those that are carried down by rivers. Those vegetables carried away by the currents, are agitated, heaped together, and broken by the waves; and afterwards become covered with strata of argillaceous or calcareous earth, and are decomposed. It is easier to conceive how these masses of vegetables may form strata of coal, than that the remains of shells should form the greater part of the globe. In confirmation of this theory, Chaptal alleges, the presence of vegetables in coal mines; the impressions of shells and of fish that are found in the strata of coal, and not unfrequently shells themselves; and also the evidence afforded by the nature of the mountains which furnish coal, from which it appears that their formation is sub-marine; for they all consist either of schistus, or grit, or limestone. The secondary schistus is a kind of coal, in which the earthy principle predominates over the bituminous. As the origin of the schistus, on which the texture of the vegetable, and the impression of fish are well preserved, is sub-marine, the same must likewise be the origin of the coal distributed in strata through its thickness. The grit-stone consists of sand heaped together, carried into the sea by rivers, and thrown up against the shores by the waves. The strata of bitumen which are found in these cannot but come from the sea. Calcareous earth rarely contains strata of coal, but is merely impregnated with it; the bitumen forming a cement with the calcareous earth.

Pit-coal is usually found in strata in the earth, almost always in mountains of schistus or grit. The secondary schistus is the basis of all pit-coal, and the quality of the coal mostly depends upon the properties of this basis. When the schistus predominates, the coal is heavy, and leaves a very abundant earthy residue after its combustion. As the formation of the pyrites, as well as that of coal, arises from the decomposition of vegetable and animal substances, all pit-coal is more or less pyritous; so that we may consider pit-coal as a mixture of pyrites, schistus, and bitumen. The different qualities of coal, therefore, arise from the difference in the proportion of these principles. When the pyrites is very abundant, the coal exhibits yellow veins of the mineral, which are decomposed as soon as they come in contact with the air; and form an efflorescence of sulphat of magnesia, of iron, of alumine, &c. When pyritous coal

is set on fire, it emits an insupportable smell of sulphur; but when the combustion is insensible, inflammation is frequently produced by the decomposition of the pyrites; and it is this which occasions the inflammation of several veins of coal. When the schistus, or slaty principle, predominates in coals, they are then of a bad quality, because their earthy residue is more considerable. The best coal is that in which the bituminous principle is the most abundant, and exempt from all impurity. This coal swells up when it burns, and the fragments adhere together; it is more particularly upon this quality that the operation called desulphurating or purifying of coal depends. This operation is analogous to that in which wood is converted into charcoal. In the desulphuration, pyramids are made, which are set on fire at the centre: when the heat has strongly penetrated the mass, and the flame issues out of the sides, it is then covered with moist earth; the combustion is suffocated, the bitumen is dissipated in smoke, and there remains only a light spongy coal, which attracts the air and humidity, and exhibits the same phenomena in its combustion as the coal of wood. When it is well made, it gives neither flame nor smoke; but it produces a stronger heat than that of an equal mass of native coal.

It was long supposed that the smell of pit-coal is unwholesome; but the contrary is now proved. M. Venel has made many experiments on this subject, and is convinced that neither men nor animals are incommoded by this vapour. Mr. Hoffman relates, that disorders of the lungs are unknown in the villages of Germany, where this material of combustion is only used. Coal of a good quality, it is supposed, does not emit any dangerous vapour: but when it is pyritous its smell must be hurtful. The use of coal is generally applicable to the arts in a variety of ways. In Scotland lord Dundonald has erected furnaces in which the bitumen is disengaged from coal, and the vapours are received and condensed in chambers, by means of water, and these condensed vapours afford an ample supply of tar. M. Faujas has carried into execution a similar process at Paris, by setting fire to coal, and extinguishing it at the proper time, so that the vapour may pass into chambers containing water for the purpose of condensing them. This tar is said to be superior to that of wood. (See TAR.) Pit-coal likewise affords ammoniac by distillation, which is dissolved in water, while the oil floats above. When coal is deprived by combustion of all its oil and other volatile principles, the earthy residue contains the sulphates of alumine, iron, magnesia, lime, &c. These salts are all formed when the combustion is slow; but when it is rapid, the sulphur is dissipated, and there remain only the aluminous, magnesian, calcareous, and other earths. The aluminous most commonly predominates. Chaptal's Elem. of Chemistry, vol. iii.

PIT, *Cock*. See COCK-PIT.

PIT, *Saw*. See SAW.

PIT of a Theatre, all that space between the amphitheatre or galleries, and the theatre or stage; called by the ancients *orchestra*; and by the French, *parterre*.

This being the most commodious part, it was here the Roman senate was placed. It has its name *pit*, in Latin *cavea*, from its being sunk below the level of the stage.

PIT-Fish, or PIT-Fisch, in *Ichthyology*, the Dutch name of an East Indian fish, approaching very much to the nature of the European turdus, but that it has no scales; its body is not flat but rounded, and is variegated with blue and yellow spots; its eyes stand very prominent, and the fish is able, at pleasure, to thrust them out or draw them in;

its back fin is prickly: it loves muddy and foul places, yet it is a very well tasted fish. See GOBIUS *Boddaerti*.

PITAMA, or PITAMAHA, in *Mythology*, the name of the god Brahma among the Hindoos; the creative power in their divine triad. See TRIMURTI.

PITAMBER, a name among Hindoo mythologists, given to their pastoral god Krishna, and sometimes also to Vishnu, and Narayana; who are probably the same deity under different names, varied according to the sectarial bias of the devotee.

PITANCIARIUS, PIETANCIARIUS, or *Pictantiarius*, an office in the ancient monasteries, whose business it was to provide and distribute the pittances of herbs and meat amongst the monks. See PITTANCE.

PITANE, in *Ancient Geography*, a town of Asia Minor, in Mysia, watered by the river Evenus, and distant 30 stadia from the mouth of the Caycus.

PITANGUA GUACU, in *Ornithology*, the name of a Brazilian bird of the starling kind, called by the Portuguese there the *bemetre*. It is of the size of the common starling; its beak is long, thick, and of a pyramidal figure; its head broad and flattened; its neck short, which, as it sits, it contracts also, so as to make it appear much shorter; its legs and feet are of a dusky brown; it has a very loud and shrill voice; its head, neck, back, wings, and tail, are all of a brownish-black, with a faint admixture of green; the lower part of the throat, the breast, and the belly, are yellow, the upper part of the throat white; its beak is very sharp-pointed. See LANIUS *Pitangua*.

PITCAIRN, ARCHIBALD, in *Biography*, an eminent physician of the mechanical school, was born at Edinburgh on the 25th of December, 1652. Having received the early part of his education at a private school at Dalkeith, he was removed to the university of Edinburgh; where, having gone through a course of philosophy, he first studied divinity, and then civil law. In consequence of his intense application his health began to suffer, and symptoms of pulmonary consumption appeared, for the removal of which he was advised to travel to Montpellier in France. His health was speedily re-established, and he determined to pursue the study of the law in that university. He found, however, that there was no able professor of that subject in Montpellier; and as he associated with several of his countrymen, who were studying physic, he was induced to change his purpose again, and adopted their pursuit. On returning to Edinburgh, thus prepared with the first elements of all the three learned professions, but undetermined which to follow, he applied himself zealously to the mathematics, in which he made great progress without a master, and was thus led, by discovering, as he supposed, the applicability of mathematical reasoning to medicine, to adopt the latter as his profession.

After studying diligently for some time the collateral branches of medicine, botany, pharmacy, and the materia medica, at Edinburgh, he went again to Paris, where he completed his medical studies, and then settled in Edinburgh, a little before the revolution, where he quickly obtained a great share of practice and an extensive reputation. In 1688, he published a little tract, entitled "Solutio Problematis de Inventoribus," the object of which was to ascertain Harvey's right to the discovery of the circulation of the blood. His extending reputation obtained for him, in 1692, an invitation from the curators of the university of Leyden to the professorship of physic in their school. He accepted this honourable appointment, and made his inaugural speech from the chair, on the 26th of April in that year: the afterwards celebrated Boerhaave was one of his pupils. His new

new method of teaching the principles of physiology and pathology on mathematical principles, was, however, not very intelligible by the students, and met with considerable opposition from the members of the faculty; infomuch that, after residing about a year, during which short space he published several dissertations illustrative of the advantages of applying mathematical principles to medicine, he quitted Leyden rather unceremoniously, deserting a chair, in which he had found himself somewhat neglected.

On his return to Scotland in 1693, he married the daughter of sir Archibald Stephenfon, an eminent physician in Edinburgh, and was induced again to settle there, when he wrote a valedictory letter to the university of Leyden. His lady did not survive her marriage many years; but she brought him a daughter, who was afterwards married to the earl of Kelly. Dr. Pitcairn died at Edinburgh on the 13th of October, 1713.

In 1701, Dr. Pitcairn republished the Dissertations which he had formerly printed, together with some additional ones; they were dedicated to professor Bellini of Pisto, who had adopted the mathematical doctrines of physiology, and had paid a similar compliment to him in his Opuscula. This edition was published in 4to. at Rotterdam, under the title of "Disputationes Medicæ," and contains eight, essays. The last edition, which appeared during his life, was published at Edinburgh, a few months before his death, under the same title; but they were reprinted in 1714 at Rotterdam, and in 1715 at Venice, under the title of "Opuscula Medica." After his death, his lectures to his pupils were published, under the title of "Elementæ Medicinæ Physico-Mathematica," Lond. 1717; and in an English translation in 1727. All his works have been collected and printed together at Venice, 1733, and Leyden, 1737, in 4to. Pitcairn used to amuse himself occasionally with writing Latin poetry, for which he had no mean talent; and a few of his compositions in this way were printed, with the title of "Poemata Selecta," which are chiefly of the epigrammatic kind. Eloy Dict. Hist. de la Medecine. Hutchinon, Biographia Medica.

PITCAIRN'S *Island*, in *Geography*, an island in the South Pacific ocean, so called by captain Carteret in 1767, after a young gentleman, son to major Pitcairn of the marines, who was lost in the Aurora, and who had discovered it. Upon approaching it, it appeared like a great rock rising out of the sea, not more than five miles in circumference, and seeming to be uninhabited. It was nevertheless covered with trees, and a stream of fresh water was observed to run down one side of it. A number of sea birds hovered round it, and the adjoining sea seemed to have fish. It is seen at the distance of more than fifteen leagues, and lies about a thousand leagues W. of the continent of America, in S. lat. 25° 2'. W. long. 133° 21'.

PITCAIRNIA, in *Botany*, received that name from M. L'Heritier, in honour of the late William Pitcairn, M. D. F. R. S. President of the College of Physicians, and a trustee of the British Museum; one of the most amiable and benevolent of men, who employed the leisure of the extensive medical practice, to which his long life was devoted, to the cultivation of a botanic garden at Islington. There he entertained his friends, and communicated his scientific riches, with the same liberality with which he bestowed the most valuable charity of his medical advice, on those who stood in need of it. In conjunction with the no less distinguished Fothergill, Dr. Pitcairn sent a person to collect on the Alps of Switzerland, many curious plants, previously unknown to English cultivators, the great number of which acquisitions may be seen in the Hortus

Kewensis of the late Mr. Aiton and his son. The name of *Hepetis*, appropriated by Swartz, from Solander's manuscripts, to this same genus, has by common consent been given up, in favour of the claims of so eminent a benefactor to botany as Dr. Pitcairn.—L'Herit. Sert. 7. Ait. Hort. Kew. ed. 1. v. 1. 401. ed. 2. v. 2. 201. Mart. Mill. Dict. v. 3. Swartz Ind. Occ. 578. Willd. Sp. Pl. v. 2. 10. Lamarek Illustr. t. 224. (Hepetis; Swartz Prodr. 56. Schreb. 798.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronarie*, Linn. *Bromeliæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in three deep, lanceolate, equal segments, converging into a tube, permanent, its base adhering to the lower half of the capsule. *Cor.* Petals three, oblong, twice the length of the calyx, cohering in the form of a tube, withering. Nectary a scale at the base of each petal. *Stam.* Filaments six, thread-shaped, shorter than the corolla, inserted into the base of the calyx; anthers erect, linear-arrow-shaped. *Pist.* Germen superior, ovate, with three furrows; style thread-shaped, the length of the stamens; stigmas three, twisted together. *Peric.* Capsule ovate, pointed, three-lobed, with three longitudinal furrows, three cells, and three valves; the partitions from the inflexed valves, soon separating at the upper part. *Seeds* numerous, minute, oblong, winged.

Ess. Ch. Calyx in three deep segments, inferior, permanent. Petals three, with a scale at the base of each. Stigmas three, twisted together. Capsule of three lobes, bursting at their inner edge. Seeds winged.

1. *P. bromeliifolia*. Scarlet Pitcairnia. L'Herit. Sert. t. 11. Ait. n. 1. Willd. n. 1. Curt. Mag. t. 824. Schneevoght Ic. t. 11. Redout. Liliac. t. 75.—Leaves fringed with spinous teeth. Flower-stalks smooth, equal to the calyx, longer than the bractæas.—Native of Jamaica, on the sides of shady rocky precipices, where it flowers in the middle of summer. Swartz. It was brought to England before 1781, and is readily increased in the stove by offsets. *Root* perennial, of numerous long stout fibres. *Stem* none. *Leaves* numerous, radical, sheathing, spreading, very long, linear, taper-pointed, channelled, keeled, smooth, moist glaucous, beneath an inch wide; their edges a little recurved, fringed with numerous spinous teeth, especially the outermost; the inner ones are often destitute of teeth, particularly upwards. *Stalk* central, radical, erect, two or three feet high, round, bearing a few toothed bractæas, or small leaves, occasionally at the bottom, the upper part racemose, somewhat pyramidal, sometimes branched, many-flowered. *Partial stalks* alternate, horizontal, simple, single-flowered, smooth, an inch long. *Bractæas* solitary at the base of each partial stalk, lanceolate, taper-pointed, coloured, shorter than the stalk, permanent. *Flowers*, as well as their common and partial stalks, and bractæas, of a beautiful rose-colour approaching to scarlet. *Calyx* an inch long, quite smooth. *Petals* more than twice as long, withering and fading quite in a different manner from the calyx. *Capsule* the length of the calyx, with long-pointed valves.

2. *P. angustifolia*. Narrow-leaved Pitcairnia. Ait. n. 2. Willd. n. 2. Redout. Liliac. t. 76. Curt. Mag. t. 1547.—Leaves fringed with spinous teeth. Flower-stalks downy, longer than the downy bractæas. Calyx downy at the base, twice the length of the flower-stalks.—Native of the island of Santa Cruz, where it was discovered by Mr. Ryan, and sent by him to Kew in 1777. It flowers in the stove in winter. This has narrower and more spinous leaves than the former; much shorter downy partial stalks and bractæas. *Flowers* variable in colour, at least in our gardens, according to the greater or less portion

tion of sunshine, from rose-colour or scarlet to pale yellow. See the Botanical Magazine.

3. *P. latifolia*. Broadish smooth-leaved Pitcairnia. Ait. n. 3. Willd. n. 3. Andr. Repof. t. 322. Curt. Mag. t. 856, excluding the synonym of Redouté.—Leaves entire; slightly spinous at the base. Flower-stalks smooth, half the length of the smooth calyx.—Native of the West Indies. The leaves are really not broader than those of the *bromeliazifolia*, but are distinguished from that, as well as from *angustifolia*, by being quite smooth and entire at the edges, except a few short crowded teeth at the very bottom. The flowers are either scarlet, or pale rose-coloured. Bractæas smooth, variable in length, sometimes equal to the partial stalks, sometimes much shorter. Calyx twice or thrice as long as its partial stalk, and, like that, quite smooth. Mr. Anderson, the very ingenious and scientific gardener of James Vere, esq. of Kensington Gore, has remarked, that this plant may be made to blossom best, by leaving it on the shelf of the dry stove, till the bud appears; after which the pot should be plunged into the bark bed. The flowers are usually produced in July or August.—We have a specimen of this species with a few spinous teeth on one leaf, towards the top. Its bractæas are woolly on their inner, or upper, surface; quite smooth beneath.

4. *P. bracteata*. Great Spiked Pitcairnia. Ait. n. 4. (*P. latifolia*; Redout. Liliac. t. 73, 74. *P. sulphurea*; Andr. Repof. t. 249.)—Leaves entire; slightly spinous at the base. Flowers nearly sessile, crowded. Bractæas as long as the calyx.—Native of the West Indies. It seems to have flowered first in the choice collection of Mr. Evans, of Stepany. Mr. Woodford, late of Vauxhall, sent it to the French gardens. This is a very striking species, whose leaves most agree with the last, with which it has been confounded. It differs from that, and every other species, in its dense spike of very numerous, crowded, nearly sessile flowers, accompanied by large bractæas, reaching as far as the points of the calyx. The corolla is either scarlet, or pale yellow; the latter seems to be occasioned by its coming out in spring, rather than in summer or autumn.

PITCH, in the Arts, a resinous substance, which is the residuum of the distillation of tar. Resin differs from pitch in being the residuum of turpentine, which is obtained from the different species of pine without heat. Tar is obtained by cutting the wood into pieces, and exposing it to the heat by a furnace for the purpose. This accounts for the blackness of the latter, arising from the decomposition of the essential oil by heat. Hence the spirit of tar differs from the spirit of turpentine merely in colour, from the presence of carbonaceous matter. See TAR and TURPENTINE.

Pitch is properly a juice of the wild pine, or pitch-tree; and is conceived to be no other than the oil thereof inspissated, and turned black, farther than in the balsam. For the method of procuring it from the wood of this tree, see PINE. See also TURPENTINE.

The best is that brought from Sweden and Norway. Its goodness consists in its being of a glossy black colour, dry, and brittle.

This is less pungent and less bitter than the liquid tar, (see TAR,) and used only in some external application, as a warm, adhesive, resinous substance. Neumann observes, that when melted with oils, resins, and fats, into ointments and plaster, the pitch is very apt to separate and precipitate. The ancients had a peculiar kind of pitch called *brutia*, which was inspissated to a higher than ordinary degree for certain uses; such as the receiving a proper quantity of bees' wax, to render it the zopiffa used in coating the bottoms of ships; which the common pitch could not do,

being of too soft a consistence for this use. Pliny tells us that it was made in this manner: the wood was cleaved and formed into a pile, with proper trenches cut in the earth to receive what run from it in burning. When the pile was lighted, the first thing that flowed into these trenches was a thin fluid liquor like water. Lamp black is the foot of burned pitch; and it is likewise prepared by collecting the foot of pit-coal. See LAMP BLACK.

PITCH, *Burgundy*, is brought to us from Saxony, and is supposed to be a preparation of the same kind with the common resin of the shops, only less divested of the oil, made by boiling the common turpentine till it acquires a due consistence. Upon making an incision into the bark of the "Pinus abies," or Norway spruce fir-tree, a clear tenacious fluid issues, which concretes into a resinous substance, known by the name of "resina abietis." This, after being boiled in water, and strained through a linen cloth, is called in the Pharmacopœias "Pix Burgundica," or Burgundy pitch. But if the boiling of the native resin is continued till the water is wholly evaporated, and wine vinegar is at this time added, a substance of the name of "Colophonium" is formed. The greatest quantity of Burgundy pitch is collected in the neighbourhood of Neufchatel, whence it is brought into this country packed in casks. A fictitious sort is made in England, and found in the shops under the title of common Burgundy pitch. It may be distinguished by its friability, want of viscosity and unctuousity, and the odour which characterises the genuine sort. Burgundy pitch is of a solid consistence, yet somewhat soft, of a reddish-brown colour, and not difagreeable in smell. It is entirely confined to external use, and was formerly an ingredient in several ointments and plasters. In inveterate coughs, affections of the lungs, and other internal complaints, plasters of the resin, by acting as a topical stimulus, are frequently found of considerable service. See PLASTER.

PITCH, *Jews'*. (See BITUMEN.) Jews' pitch, or asphalt, is black, brilliant, ponderous, and very brittle. It emits a smell by friction; and is found floating on the water of the lake Asphaltites, or the Dead sea. The asphaltites of commerce is extracted from the mine of Annemora, and more particularly in the principality of Neufchatel. M. Pallás found springs of asphaltites on the banks of the Sock, in Persia. Most naturalists, says Chaptal, consider it as amber, decomposed by fire. It liquefies on the fire, swells up and affords flame, with an acrid disagreeable smoke. By distillation it affords an oil resembling petroleum. The Indians and Arabs use it instead of tar; and it is a component part of the varnish of the Chinese.

PITCH, *Mineral*. (See BITUMEN.) This is a modification of petroleum. It is found in France, in Auvergne, at a place called Puits de Lapege, near Allais, over an extent of several leagues. The calcareous stone is impregnated with a bitumen, which is softened by the heat of summer, when it flows from the rocks, and forms a very beautiful stalactites. It forms masses in the fields; and impedes the passage of carriages: the peasants use it to mark their sheep. This stone, when rubbed, emits a filthy smell. Some have asserted that mineral pitch was used to cement the walls of Babylon.

PITCH, *Naval*, *pix navalis*, is that drawn from old pines, ranged and burnt like charcoal. This, with a mixture of tow, or beaten cables, serves for paying over the seams of a ship's sides and decks, after they are caulked, to preserve the oakum from any wet; and likewise over all the surface of the bottom and wales: to pay the two latter it is softened with oil.

PITCH, *Naval*, is also a denomination given to that scraped from

from off the sides of old vessels; and which is supposed to have acquired an astringent virtue, by means of the salt water. It serves to make plasters; though it is certain the apothecaries usually substitute the common black pitch in its stead.

PITCH, *Greek*, or *Spanish pitch*, is that boiled in water till it has lost its natural smell; upon which it becomes dry and friable.

The ancients called it *colophony*; from Colophon, a city in Greece, whence great quantities were brought. See **COLOPHON**, and *Burgundy PITCH*, *supra*.

PITCH, *Oil of, oleum picinum*, is an oil procured from pitch, by separating the aqueous matter that swims a-top of the melted pitch. This, from the great virtues formerly attributed to it, was also called *balsam of pitch*.

PITCH, *Ointment of*, is made by melting tar with an equal weight of mutton suet, and straining the mixture whilst hot: this is used sometimes as a digestive, and said to be particularly serviceable against scorbutic and other cutaneous eruptions. See **TAR**.

PITCH, *Pills of*, are made of tar mixed with so much powdered liquorice, or other such powdered matter as is sufficient to render it of due consistence for being formed into pills. See **TAR**.

PITCH of Castro, in the *Materia Medica*, the name given by Boccone and some other writers to a thick kind of bitumen, found issuing out of the cracks of some rocks near the village of Castro: from whence it has its name: it is famous in the ecclesiastical state for its medicinal virtues.

PITCH, in *Building*, denotes the angle or gable end.

If the length of each rafter be three-fourths of the breadth of the building, the roof is said to be *true pitch*. This is used when the covering is of plain tiles.

If the rafters be longer, it is said to be a *high or sharp-pitched roof*; if shorter, which seldom happens, it is said to be a *low or flat-pitched roof*.

If the length of the principal rafters be equal to the breadth of the building, it is called *Gothic pitch*. This is used when the covering is of pantiles.

If to rule as a pediment, it is said to be *pediment pitch*. The perpendicular height of this pitch, is equal to $\frac{2}{3}$ ths of the breadth of the building. This pitch is used when the covering is lead.

PITCH, in *Music*, implies the elevation or depression of the general scale. There is no term more common among musicians,—who have the Roman pitch, the opera pitch, the organ pitch, the concert pitch. By the first is understood a *low pitch*; by the second, the *true* and most general pitch; by the third, a *high pitch*; as almost all church organs are pitched very high by the builders, we believe, to save metal; of which more is necessary for a long than a short pipe of the same diameter: and by the fourth, a varied pitch, according to the state an instrument is found in by persons who had never met before.

To PITCH a Camp, in *Military Language*, signifies to take a position, and encamp troops upon it according to the principles of *castrametation*; which see. See also **CAMP**.

To PITCH a Tent, is to place a certain prescribed quantity of canvas upon poles, so as to afford a temporary cover against the inclemency of the weather, for one or more officers or private soldiers. In order that the men may be expert in pitching or striking tents, they should be practised whilst in camp in both operations.

PITCH, in *Rural Economy*, a fork full of hay, corn, or straw, or as much as is raised to the load, stack, or mow, at one time.

PITCH-Fork, a sort of fork with two prongs, which is

in use for pitching different substances, as hay, corn, straw, &c., to the cart, mow, stack, or other places; and which is usually made larger and longer in the handle than the common hay fork.

PITCH-Ore, in *Mineralogy*, a species of the genus Uran, is of a velvet-black colour, or dark greyish-black, which inclines to iron-black. It occurs generally massive, and disseminated: internally it is shining, inclining to glistening, and its lustre is resinous. The fracture is imperfect and flat: the fragments indeterminately angular, and sharp-edged. It occurs sometimes in thick and curved lamellæ; sometimes in coarse and distinct concretions, resembling red hematite. In the streak, neither colour nor lustre is changed. It is soft, brittle, and heavy. The specific gravity is variously given: by Guyton it is said to be 6.38; by Haüy, 6.53; and by Klaproth it is said to be 7.5. It is infusible, without addition, before the blowpipe. With soda or borax it forms a grey, muddy, flaggy-like globule; with phosphoric salts it makes a transparent green bead. It dissolves imperfectly in the sulphuric or muriatic acids, and from this solution, which has a pale orange-yellow colour, the uranium is precipitated brownish-red by prussiat of potash, and yellow by the alkalies. According to Klaproth its constituent parts are,

Uran	86.5
Black oxyd of iron	2.5
Sulphurated lead	6.0
Silica	5.0
	—
	100.0
	—

By the analysis of other chemists it is said to contain only uranium and iron, but neither sulphurated lead nor silica; and in another specimen were found sulphur and a small portion of copper. It is found in veins in primitive mountains with lead and silver ores. It is usually accompanied with lead-glance, copper-pyrites, iron-ochre, calc-spar; sometimes with cobalt-glance, red cobalt-ochre, silver-glance, uranium-mica and uranium-ochre. It is found in several parts of Saxony, Bohemia, and Norway, and is distinguished from brown-blende by colour, specific-gravity, fracture and streak; from wolfram, by its streak and fracture.

PITCH-Tree, in *Botany*. See **PINE-Tree** and **PINUS**.

PITCHED, in *Sea Language*. They say the mast is pitched, when it is put or let down into the step; also the mast is pitched too far aft, when placed too near the stern. When a ship falls with her head too much into the sea, or beats against it so as to endanger her top-masts, they say, she will *pitch her masts by the board*.

This motion may proceed from two causes; the waves which agitate the vessel, and the winds upon the sails, which make her stoop to every blast thereof.

PITCHER, in *Agriculture*, the labourer or person who is employed in pitching.

PITCHET, in *Geography*, a town of Upper Siam; 40 miles S. of Porfeloue.

PITCHIN, a town of Persia, in the province of Mekran; 100 miles W. of Kidge.

PITCHING. See **PAVEMENT**.

PITCHING, in *Seaman'ship*, the inclination or vibration of the ship lengthwise about her centre of gravity; or the motion by which she plunges her head and after-part alternately into the hollow of the sea. This is a very dangerous motion, and when considerable, not only retards the ship's way, but endangers the masts and strains the vessel. This motion proceeds from two causes; viz. from the vessel's improper construction, or the ill arrangement of her cargo. See **SHIPBUILDING**.

PITCHING-Pence, a duty, commonly of one penny, paid for pitching or setting down every sack of corn, or pack of merchandize, in a fair or market.

PITCHSTONE, in *Mineralogy*, a species of the clay genus, of which the colours are black, green, brown, red, and sometimes, but rarely, grey. Of the black, there are the greenish, greyish, and brownish-black. From greenish-black it passes through blackish-green into mountain-green, asparagus-green, leek-green, olive-green, and oil-green. From olive-green it passes into liver-brown, yellowish and reddish-brown, and again into light-blood and brick-red. The varieties of the grey are smoke and dark ash-grey, and sometimes a kind of grey which passes into brown. It has sometimes a blueish colour. Its colours are not lively, but always somewhat deep and muddy, or rather mixed with grey and brown. It is generally uniform, and it seldom happens that several colours occur together. It is found almost always massive, in great beds and rocks. Internally its lustre is shining, sometimes splendent, sometimes glistening, and intermediate between resinous and vitreous, yet more inclining to the first. The fracture passes from the large conchoidal into the coarse splintery and coarse grained uneven. The fragments are indeterminately angular, more or less sharp-edged. It occurs sometimes in coarse distinct concretions, and the surface of the concretions is somewhat bent; also in prismatic generally wedge-shaped distinct concretions, of which the surface is smooth. It is commonly translucent in a small degree; the black variety is only translucent on the edges. It is brittle; easily frangible, and not very heavy. The specific gravity of the Saxon pitchstone is about 2.3. Before the blowpipe it is fusible without addition. The black variety, heated to 21° of Wedgwood's pyrometer, swelled a little, its colour was slightly altered, the surface glazed, and internally it was porous; at 31° it was softened; at 65°, the intumescence was more considerable; and at 100° it was still vesicular, but more compact. The blackish-green variety found at Arran becomes black, is much rent, and internally porous at 23°; at 55° it formed a porous enamel; at 70° it became perfectly white and still porous. The pitchstone of Meissen, by analysis, gave of

Silica	73.00
Alumine	14.50
Lime	1.00
Oxyd of iron	1.00
Oxyd of manganese	0.10
Natron	1.75
Water	8.50
	<hr/>
	99.85
Loss	15
	<hr/>
	100.00

It occurs in beds in the newer porphyry formations, and in beds and veins that belong to the newest stoz trap formation. It is found in great quantity in the electorate of Saxony, particularly in the neighbourhood of Meissen, also in Hungary, as at Tokay and Schemnitz; in some of the islands of the Archipelago, where it was first observed by Mr. Hawkins; and at Glamocard in the island of Skye. It was first discovered about sixty years ago in the neighbourhood of Meissen in the electorate of Saxony, and was named pitchstone from the striking resemblance which several of its varieties bear to pitch.

PITCHT, SHOULDER. See *SHOULDER Pitcht*.

PITCHY Iron-Ore, in *Mineralogy*, a metallic fossil, of a very deep reddish-brown, which sometimes passes into

black. It occurs massive with a rough surface, owing to a covering of iron-ochre. Internally it is glistening, and its lustre is semi-metallic, passing into resinous. The fracture is compact, and sometimes foliated. It is opaque, not easily frangible, and brittle. Its specific gravity is nearly 4. It melts very easily into a black enamel before the blowpipe; and its constituent parts are, phosphoric acid, oxyd of iron, and oxyd of manganese. It is found at Limoges in France.

PITEA, or **PITHEA**, in *Geography*, a sea-port town of Sweden, in East Bothnia, situated on a small island at the mouth of a river of the same name: joined to the continent by a wooden bridge. The streets are parallel, and the church is at a considerable distance from the town. It has a commodious harbour and a good school. It was first built in 1621 by Gustavus Adolphus, three miles from its present site higher in the country; but in 1666 this town was destroyed by fire, and the present town was built in its present situation. N. lat. 65° 23'. E. long. 21° 22'.

PI-TEOU, a small island near the coast of China. N. lat. 25° 20'. E. long. 119° 14'.

PITESZTI, a town of Walachia; 50 miles N.W. of Bucharest. N. lat. 44° 57'. E. long. 24° 49'.

PITH, in *Vegetable Physiology*. See **MEDULLA**.

PITHECALOPEX, the *Semivulpa*, or *Ape-fox*, in *Zoology*, a name given by Aldrovandus and some others to that strange American animal which we call the opossum.

The name is compounded of that of the fox and the ape; of the natures of both which animals it is supposed by some to participate.

PITHECON PORTUS, in *Ancient Geography*, a port of Africa, in Libya, near Carthage.

PITHECUSSÆ, islands of the Tyrrhenian sea, near the coasts of Campania.

PITHIAS, or **PITHITES**, with some writers, a sort of comet, or rather meteor, in form of a tub. Of these it is said there are divers kinds, viz. some of an oval figure, others like a tun or barrel set perpendicular, and some like one inclined or cut short off; others having a hairy train or bush, &c.

PITHING, the name of an operation performed for killing animals suddenly and without pain. This is effected with a narrow doubled-edged poniard passed in between the skull and first vertebra of the neck: in this way the medulla oblongata is divided, and the animal instantaneously deprived of sensibility. This operation was performed by Mr. Cline junior, assisted by Mr. Brodie and Mr. Clift, on a camel that had been the subject of Mr. Home's experiments. (See *Phil. Trans.* vol. xcvi. p. 359.) In the common mode of pithing cattle, the medulla spinalis only is cut through, and the head remains alive, which renders it the most cruel mode of killing animals that could be invented. See *Dr. Dugard's Experiments*, published in the Board of Agriculture's Report for Shropshire, by Joseph Plumley, M. A. p. 246.

PITHIVIERS, in *Geography*, a town of France, and principal place of a district, in the department of the Loiret; 21 miles E.N.E. of Orleans. The place contains 3071, and the canton 15,275 inhabitants, on a territory of 302½ kilometres, in 22 communes. N. lat. 48° 11'. E. long. 2° 24'.

PITHOU, **PETER**, in *Biography*, a magistrate distinguished for his integrity and erudition, was born in 1539 at Troyes, in Champagne. He received a good education, after which he studied the law as a profession. When called to the bar his natural diffidence so completely embarrassed him, that he found it necessary to renounce that branch of his profession. Being of the reformed religion he had nearly been sacrificed

sacrificed at the horrid massacre of St. Bartholomew's day, which probably had such an effect upon his mind, naturally timid, that in the following year he conformed to the Catholic church, and soon after obtained the office of attorney-general in the chamber of justice in Guienne. When Gregory XIII. had issued a brief against the ordinance of Henry III., concerning the council of Trent, Pithou published a memoir, in which he developed the secret purposes of the brief, and vigorously defended the cause of his king and country. After Henry IVth's conversion, as it has been called, he used his best endeavours to reduce the city of Paris to allegiance. He was one of the writers of the "Catholicon d'Espagne," a satire which proved very effectual in throwing ridicule upon the Spanish party. He also published a little work, which he pretended was a translation from the Italian, entitled "Raïsons pour lesquelles les Evêques de France ont pu de droit donner l'Absolution à Henry de Bourbon," which was several times printed, and which made many converts to the royal cause. He died in the year 1596, at the age of 57. He is represented by De Thou as one of the first men of the age, as well for probity, candour, and real piety, as for the extent of his learning, the soundness of his judgment, and his political wisdom. He had a most intimate acquaintance with every thing relative to French history and antiquities, and his profound knowledge of the civil law, in which he was scarcely inferior to Cujas himself, under whom, in his youth, he had studied. The works of this gentleman are, "Traité des Libertés de l'Eglise Gallicane," in four vols. folio, and which is thought to be the basis of all that has been written on the same subject: "A commentary on the Customs of Troyes," and other tracts on civil and canonical jurisprudence. He published, in 1609, a large collection of "Opuscules," also editions of several monuments of antiquity, chiefly relating to the history of France. He had collected a curious and very valuable library, rich in MSS., which by his will he directed to be sold only to a single purchaser acquainted with its value; this precaution, however, did not prevent its dispersion. By his deep and extensive erudition he acquired the title of the French Varro, and his name was not less celebrated abroad than in his own country. Gen. Biog.

PITHOU, FRANCIS, brother of the preceding, born in 1544, was likewise brought up to the law, and exercised the office of attorney-general to the chamber of justice, established by Henry IV. to check the frauds of the financiers. He assisted at the conferences of Fontainebleau, and was one of the commissioners for regulating the boundaries between France and the Low Countries. After this he retired, passing his life in study, emulating his brother in the variety and depth of his learned researches. He died in 1621. He took a part in most of his brother's publications, and especially contributed to the elucidation of the "Body of Canon Law," printed at Paris, in two vols. fol. He was author likewise of several works, of which the chief are, "La Conférence des Lois Romaines avec celles de Moyse;" an edition of the "Salic Law," with notes; "Traité de la Grandeur et Droits du Roi et du Royaume de France." He published an edition of the "Antiqui Rhetores Latini," 1599. He discovered "Phædrus' Fables," which he published in conjunction with his brother. The names of the two brothers are very celebrated among men of letters. A full and exact catalogue of their several publications is prefixed to their works in Latin, printed in 1715. Moreri.

PITHYUSA, in *Botany*, a name used by many authors for a small species of spurge.

PITI, in *Geography*, a town of Thibet; 204 miles S. of Latac.

PITIES, in *Commerce*, the only money of the natives of the isle of Java, which is a small coin containing four parts of lead and one of tin; 25 of these pass for two duysts, each duyst being a fourth part of the copper coin, called the stiver.

PITIGLIANO, in *Geography*, a town and fortress of Etruria; 23 miles E.N.E. of Orbitello.

PITHEMPO, a mountain of Asia, which bounds Thibet to the north-west.

PITINUM, in *Ancient Geography*, a town of Italy, in the territory called by Pliny "Pitinas Ager," on the other side of the Apennines, and watered by the river Novanus. Ptolemy assigns this town to the Umbrians who inhabited the territory N. of the Tuscan.

PITISCUS, SAMUEL, in *Biography*, a learned philologist, was born at Zutphen in 1637. He studied under J. Fr. Gronovius at Deventer, and afterwards went through a course of theology at Groningen. When he had completed his education, he was made master of the school at Zutphen, and, in 1685, he was promoted to be rector of the college of St. Jerom at Utrecht. He died at a very advanced age at Utrecht, in the year 1717. He was author of "A Latin and Dutch Dictionary;" but his principal work was "Lexicon Antiquitatum Romanarum," in two vols. fol. the labour of ten years of his life; a performance well known to the learned world. He also gave a new and improved edition of the "Roman Antiquities" of Rosin, and of Pomey's "Pantheon Myisticum."

PITIVILCO *la Baranca*, in *Geography*, a town of Peru, in the diocese of Lima; 28 miles N.N.W. of Guaura.

PITKEATHLY or PITCAITHLY, a village in the parish of Dumbarry, and county of Perth, Scotland, is seated in a sequestered corner of the rich vale of Stratherne, at the distance of four or five miles from Perth. It has been long celebrated for its mineral springs, and of late years has become a place of very fashionable resort. In the efficacy of the waters for the cure of scrofula, scurvy, gravel, and complaints in the stomach and bowels, Pitkethly wells are generally considered equal, if not superior, to any in North Britain; and the village yields to none in beauty and agreeableness of situation. There are here five distinct springs of different degrees of strength, but all partaking of the same qualities. The chief mineralizers are muriate of soda (common salt) and muriate of lime, with a portion of chalk and Paris plaster held in solution. An account of these waters, and of their medicinal uses, was published in the 62d volume of the Philosophical Transactions. The period of their discovery cannot be ascertained; as even tradition is silent upon the subject.

The parish of Dumbarry is about four miles in length and three in breadth. The soil is extremely fertile, and the surface finely diversified with level and rising grounds, wood, and water. The river Earn runs through the middle of the parish; and on one side it is bounded by the hill of Mordun or Moncreiff, the view from which is characterized by Pennant as "the glory of Scotland." The bridge over the Earn here is of great antiquity, and is kept in repair by the magistrates of Perth. Carlisle's Topographical Dictionary of Scotland, vol. i. 4to. Beauties of Scotland, vol. iv.

PITLAND, a town of Hindooistan, in Guzerat; 18 miles N.E. of Cambay.

PITLAR, a town of Russia, in the government of Tobolsk; 48 miles S. of Obdorskoi.

PITLAWAD, a town of Hindooistan, in the circar of Banskwalch; 12 miles S. of Tandla.

PITOE, a town Thibet; 24 miles W.N.W. of Latac.

PITON POINT, the S.W. point of the island of St. Lucia.

PITOT, HENRY, in *Biography*, a mathematician and engineer in the 18th century, was descended of a noble family of Languedoc, and born in the year 1695. His genius inclining him to the mathematical sciences, he made himself a proficient in them without the aid of a tutor. At the age of twenty-three he went to Paris, and became intimately acquainted with Reaumur. In 1724 he was received into the Academy of Sciences, of which he was elected a pensioner not many years afterwards. He was author of a highly esteemed work, entitled "The Theory of working Ships," 1731, which was so highly esteemed, that on account of it, he was elected a member of the Royal Society of London. In 1740, the states-general of Languedoc gave him the appointment of principal engineer to the province, and also that of inspector-general of the famous canal, which forms a navigable junction between the Mediterranean sea and the bay of Biscay. "Many monuments of his genius," says his biographer, "which will transmit his name with honour to posterity, may be seen in different parts of Languedoc; and, in particular, a noble plan designed and executed by him for supplying Montpellier with water from sources at the distance of three leagues, which has deservedly excited the admiration of travellers. Out of respect to his merits, the Royal Academy of Sciences at Montpellier inscribed his name in the list of their members, and the king honoured him with the order of St. Michael." He died in 1771, at the age of 76, esteemed for his probity and disinterestedness, and highly respected for his science and ingenuity.

PITQUIN, in *Geography*, a town of New Mexico, and capital of the province of Sonora; 900 miles N.W. of Mexico. N. lat. 29° 56'. W. long. 112° 12'.

PITRIOWIN, a town of Austrian Poland, in Galicia; 32 miles S.W. of Lublin.

PITRIPETI, in *Mythology*, a name of the Hindoo deity Yama, who corresponds with the Pluto of western mythologists. See YAMA.

PITRIS, a class of beings with the Hindoos, to whom reverence is paid in their sacrificial ceremonies. They sometimes seem to bear the character of patriarchs, or sages of former days, and at others the moon is assigned for their habitation. The word often occurs in Hindoo books, but apparently without any precise signification attached to it. In the institutes of Menu, they are thus described. "The Pitris, or great progenitors, are free from wrath; intent on purity; ever exempt from sexual passions; endued with exalted qualities: they are primeval deities, who have laid arms aside." "From the Rishis come the Pitris, or patriarchs," &c. ch. iii. v. 192. 200. See RISHIS.

PITSCHEN, or BITSCHEN, in *Geography*, a town of Silesia, in the principality of Brieg; surrounded with walls, and containing two churches and a college; 30 miles N.E. of Brieg. N. lat. 51° 8'. E. long. 18° 15'.

PITSHAN, a town of Little Bucharria; 30 miles E.N.E. of Tourfan.

PITSYLVANIA. See PITTSYLVANIA.

PITT, CHRISTOPHER, in *Biography* an English poet, son of a physician, was born at Blandford, in Dorsetshire, in the year 1699. He was educated in Winchester school, where he was distinguished for his assiduity in study, for his taste as a general scholar, and as a writer of English verse. On leaving Winchester, he was elected to New college, Oxford, and as an acknowledgement of the kindness of the

electors, he presented them with two manuscript volumes of poems, of which one was miscellaneous, and the other contained a complete version of Lucan's Pharsalia. He was intended for the church, and after three years residence at college, he was presented, in 1722, to the rectory of Pimperm, in Dorsetshire, to which place he retired after a further continuance of two years at Oxford, when he had taken his degree of M.A. Here he passed the remainder of his life in an easy situation, maintaining a social and very friendly intercourse with many persons of rank and literary eminence. He died in 1748, in the 49th year of his age, generally respected and beloved. In 1727, he published a volume of Miscellaneous Poems; after which he produced a translation of Vida's Art of Poetry, which possesses much of the elegance and high polish of the original. His success in this department of literature encouraged him to undertake the task of translating Virgil's *Æneid*, which he completed in 1738, and published in two vols. 4to. in 1740. "This translation," says his biographer, "if Dryden's had not existed, would have been considered as a very valuable addition to the mass of English poetry; and even in competition with that work, it may sustain itself by its different merits." It is certainly much more exact to the original, not only in meaning, but in that polish and refinement, which is so often violated by the coarseness of Dryden. It is also by no means deficient in strength and vigour; but it cannot boast of those happinesses of expression, that glow and elevation, which in the best passages of Dryden give the stamp of original genius. Pitt's translation, however, has taken a firm hold on the public, and has been repeatedly reprinted in a complete edition of Virgil in English verse, of which the *Eclogues* and *Georgics* were contributed by Dr. Warton, with various critical dissertations by himself and others. Johnson's English Poets.

PITT, WILLIAM, earl of Chatham, one of the most illustrious statesmen that ever lived, was second son of Robert Pitt, and Harriet Villiers, sister to the earl of Grandison. He was born, by his own account, entered on the books of Oxford, in St. James' parish, on the 15th of November 1708. He received the early part of his education at Eton, as a scholar on the foundation, and at the age of eighteen he was entered of Trinity college, Oxford, as a gentleman-commoner. Of his academical reputation little is known, but a copy of Latin verses on the death of George I., published in the university tribute on that occasion, may be found in the *Anecdotes of his Life*, &c. in three vols. 8vo. to which we shall have frequent recourse in the present article. Before he left Eton, he was occasionally afflicted with an hereditary gout, which increased during his residence at Oxford, and which at length obliged him to quit the university without taking a degree. He afterwards made the tour of part of France and part of Italy, but his disorder was too deeply rooted in his constitution to be removed by foreign travel. He, however, constantly employed the leisure, which this painful and tedious malady afforded, in the cultivation and improvement of his mind.

He first came into parliament in the month of February 1735, for the borough of Old Sarum, and being a younger brother of a large family, his fortune was inconsiderable, and his friends obtained for him a cornet's commission in the Blues. The first time Mr. Pitt spoke in the house of commons, was to second the motion of his friend Mr. (afterwards lord) Lyttelton, for a congratulatory address to his majesty, on the marriage of Frederic, prince of Wales. His exertions on this occasion obtained for him the marked attention of the prince, who was then at the

head

head of the opposition party. With this party Mr. Pitt uniformly voted, by which he incurred the displeasure of sir Robert Walpole, who revenged himself by taking away his commission: which fact was celebrated by the following lines of his friend Lyttelton, ironically complimenting the minister for snatching the servile standard from his hand, and raising him to patriotic eminence.

“ Long had thy virtues marked thee out for fame
Far, far superior to a Cornet’s name;
This *gen’rous Walpole* saw, and griev’d to find
So mean a post disgrace that noble mind:
The servile standard from the free-born hand
He took, and bad thee lead the patriot band.”

Mr. Pitt very soon attained the first place, for eloquence, in the ranks of opposition, and the minister soon repented his rashness in making him his enemy. This illustrious young man was distinguished for a fine figure, an expressive countenance, and a melodious voice. A keen eye, a graceful manner, and pleasing address, gave lustre and effect to a copious elocution, not, at first, highly correct, but animated with the fire of genius, and frequently marked with passages of singular force and energy that impressed themselves upon the memory, and were almost irresistible in their effect. “The records of the British senate,” it is said, “scarcely present another name so distinguished by that eloquence which bears away with it the passions and convictions of the hearer, and strikes an antagonist with awe. To these powers he added true elevation of mind, honour, integrity, and pure constitutional principles.” Without attempting to trace all the steps of this statesman’s progress from an oppositionist to a member of administration; we may briefly observe, that he continually rose in the esteem of the nation, as an able and vigilant opposer of all measures that appeared to him to be unconstitutional. Seven of his speeches preserved in Chandler’s Debates, and which were delivered during the remainder of sir Robert Walpole’s administration, exhibit the ardour of his mind, and the comprehensiveness of his views as a young but truly enlightened statesman; but his most important speech in this period of his life, was in support of a motion for inquiry into sir Robert Walpole’s (then earl of Orford) conduct. The motion was at first lost, but when introduced a second time, limiting the retrospect to the last ten years, it was carried; but by a ministerial manoeuvre the inquiry was defeated. To popular applause was added a more substantial testimony of approbation of his conduct, by Sarah, duchess of Marlborough, who, in a codicil to her will, dated in 1744, bequeathed him the sum of ten thousand pounds on the grounds of his public services. In 1745 Mr. Pitt was mentioned to the king, George II., by the duke of Newcastle, as a proper person to fill the office of secretary at war; but so obnoxious was his name to his majesty, probably on account of his constant opposition to Hanoverian politics, that he was decidedly, and at once, rejected, and a general resignation of the Pelham party followed. In the following year they were re-mitted, and Mr. Pitt was appointed to the office of vice-treasurer of Ireland. He soon after succeeded to the lucrative place of pay-master of the forces, which gave him an opportunity of shewing how disinterested he was with regard to pecuniary concerns. His predecessors had always held very large sums of the public money in their hands, of which they made advantage by means of the funds, but Mr. Pitt never once availed himself of his situation for his own private emolument. He even refused the usual perquisite upon a subsidy voted to the king of Sardinia, nor would he accept of any present in lieu of it. In 1754 Mr. Pitt

married Hester, daughter of Richard Grenville, a lady of great merit, of a highly cultivated mind, and of general and very extensive knowledge, with whom he passed the remainder of his life in uninterrupted harmony.

In 1755, when the king returned from Hanover, bringing subsidiary treaties with Hesse-Cassel, and Russia for its defence, he did not scruple to join Mr. Legge in opposing their ratification by parliament. On this account they were both dismissed, together with Messrs. George and Richard Grenville. It should be noticed, as exhibiting a prominent feature in Mr. Pitt’s character, that when turned out of his situation, the balances belonging to his office were all lodged in the bank. Those who encouraged the many attempts to throw a shade upon his moral character, were the discoverers of the fact, to their own utter mortification and confusion. Mr. Pitt was now an eager oppositionist, and spoke with honest indignation against the favourite measures of introducing foreign troops for the defence of the kingdom, and protecting Hanover by subsidies; the natural force of the nation, he said, was sufficient to repel any attack of the enemy. That state alone is worthy of being denominated a sovereign state, *qui suis stat viribus, non alieno pendet arbitrio*: which depends on its own strength, and not on foreign assistance. The disasters with which the new war began, occasioned great dissatisfaction with the conduct of public affairs, and the nation eagerly expected a change of men and measures; and in the autumn of 1756 a new administration was formed, in which Mr. Pitt took the place of secretary of state. The aspect of affairs was instantly changed; and the vigour infused into the public councils became immediately apparent by the formation of a national militia, to which the internal defence of the country was entrusted, while the foreign mercenaries were sent away:—by the levying of a body of Highlanders to serve in North America:—by the dispatching of squadrons of men of war to the East and West Indies, and by a successful expedition to Goree on the African coast. Mr. Pitt was still inimical to the war in Germany, at least under the conduct of the duke of Cumberland; on which account he and his friends were dismissed from office. The public discontent at this measure was manifested in the most marked and decisive manner, and his majesty invited him very soon after to take the efficient post in the ministry on any terms that were agreeable to him. He resumed his post of secretary, and arranged a ministry according to his own views of the necessity of the case, and it was that administration which raised the British nation from a state of depression and disgrace to the highest pitch of glory and success. Of this ministry he was the soul, and he infused his own spirit through every department of the state. The principle upon which he acted was, to disregard all party distinctions; all family interests; and to employ men of real talents wherever he found them. Instead of inactive and incapable commanders, whom he found in the service, he filled the army and navy with men raised to notice by their abilities and exertions. By a perpetual series of enterprizes he kept all the national powers on the alert, and assaulted the enemy in every quarter of the globe. He gave all his own time to business and none to parade, not holding a single levee during his secretaryship. He first accurately informed himself of the practicability of his plans, and then was most peremptory in his orders; and he provided, with the most wonderful foresight, against every emergency. The history of Mr. Pitt’s administration is so interwoven with the annals of the country, and the public events that occurred in it are so well known, that it will be sufficient if we give a mere summary of the most important; and previously to this we may shew the extent of his ministerial influence

fluence on his second promotion to the administration in 1757, of which we are now speaking. Mr. Pitt's first proposition, says the author of the Anecdotes, was the exclusion of lord Anson from the cabinet. The duke of Newcastle pleaded earnestly to have lord Hardwicke in the cabinet: he said it was the king's request. Mr. Pitt consented, on condition that sir Robert Henley had the great seal; this stipulation was desired by Leicester-house. Lord Temple was to be privy seal: himself secretary of state. The duke of Newcastle offered lord Temple the treasury: Mr. Pitt interposed, and said it could not be, his grace must go there himself; but if, at any time hereafter, he should think proper to retire, lord Temple should succeed him. Lord Anson was proposed for the admiralty; Mr. Pitt declared that lord Anson should never have the correspondence. The duke replied that such an alteration could not be made without his majesty's consent. Here the conference broke off. Mr. Pitt soon after had an audience with the king, when he laid before him the difference that had occurred between the duke of Newcastle and himself, concerning the admiralty. The king immediately consented that the correspondence with the naval officers, usually in the board of admiralty, should be given to Mr. Pitt, and that the board should sign the dispatches without being privy to their contents. It was at this audience Mr. Pitt said, "Sire, give me your confidence, and I will deserve it;" to which the king instantly replied "Deserve my confidence, and you shall have it;" and it is understood to have been a fact that Mr. Pitt at length so won upon the king, that he was able to turn his partialities in favour of Germany to the benefit of his country.

At the period we are speaking of, the duke of Cumberland had utterly failed in the attempt to rescue Hanover from the French, and had been obliged to make a disgraceful convention: this, for the moment, seemed to be a termination of the English interference in German affairs, but the king's predilections were not to be so defeated. He refused to ratify the convention, and was intent upon some opportunity for renewing military operations in that country, and to this, upon the victory of the king of Prussia over the French, the minister acceded, though on account of it he incurred much obloquy, and his popularity underwent a severe trial. The allied army was now to be commanded by Ferdinand, duke of Brunswick, a general of the highest reputation; the king of Prussia was to be enabled by a large subsidy to co-operate with all the effect to be expected from his extraordinary talents; and thus a diversion might be given to the French force, which would render the British arms superior in all other quarters. The event proved the justice of such expectations, and the minister seemed warranted in his emphatic sentence that America was conquered in Germany. The years 1758, 9, 60, and 61, were marked by a series of successes, interrupted almost solely by the failure of some expeditions to the coast of France; but these served to keep that country in a state of alarm, and retaliate upon it the fear of invasion which had so disgracefully depressed England at the beginning of the war. At the end of that period the navy of France was nearly annihilated, and it had scarcely a colony or settlement left in any part of the world. In the mean time, however, a change in the crown had taken place, the old king had died, and his present majesty, George III., had succeeded to the throne. The confidential, but secret advisers of the new sovereign, looked to new measures; they regarded with jealousy the vast ascendancy of the minister, then emphatically styled the *great commoner*, and his warlike spirit was considered as adverse to the re-establishment of peace, which now began to

be a national wish. A negotiation with France was commenced, which was rendered abortive by the intermixture of the concerns of Spain with those of this country. This intermixture was reſented in ſtrong language by Mr. Pitt, who being, at that time, furniſhed with intelligence of the treaty of alliance between all the branches of the houſe of Bourbon, called the *family compact*, warmly urged in the cabinet an immediate commencement of hoſtilities againſt Spain. He was over-ruled, and he determined that he would be no longer reſponſible for meaſures which he could not guide. He reſigned his poſt in October 1761, and was accompanied in his retreat by lord Temple. His paſt ſervices were rewarded with a peerage conferred on his wife by the ſtyle and title of baroneſs of Chatham, and an annuity of 3000*l.* for his own life and her's. Mr. Pitt now returned to the condition of a private member of parliament with his fortune ſo little improved by the poſts which he had held, that his principal ſupport was his annuity. He took no leading part in the ſubſequent debates, but when the preliminaries of peace, in 1762, came to be diſcuſſed in parliament, he ſpoke in ſtrong terms againſt many of the provisions of them. When the queſtion of general warrants was moved, in 1764, Mr. Pitt ſpoke againſt their legality; and during all the conteſts between the prerogative of the crown and liberty of the ſubject, which agitated the early part of the preſent reign, he uniformly ſupported the popular cauſe. On account of his high character for patriotiſm, a conſiderable acceſſion to his fortune was produced in 1765, on the death of ſir William Pynſent, who bequeathed him an eſtate of 3000*l.* a-year. In 1766 the formation of a new miniſtry was committed to him, and on this occaſion he took the office of privy-ſeal, and was himſelf raiſed to the peerage, with the title of the earl of Chatham. He was, in this inſtance, deſerted by his early and intimate aſſociate lord Temple, and the marquis of Rockingham; while other men of rank and talents reſuſed to join him; diſguſted, it was believed, by the tone of ſuperiority and haughtineſs which he was too much in the habit of aſſuming. His adminiſtration was therefore fluctuating and unſteady; his own influence gradually declined, and upon his reſignation in 1768, he was ſo far fallen in public eſtimation, that he was ſcarcely miſſed by the public. The fire of his genius was not, however, extinct, and he was roused to exertions worthy of his former reputation. He took a leading part in all the great popular queſtions at that time diſcuſſed in and out of parliament. He began with a ſpirited attack in the houſe of lords upon the proceedings of the houſe of commons in the caſe of the Middleſex election. The doctrine of libels, as laid down by lord Mauſfield, was another ſubject on which the earl of Chatham vigorouſly maintained the principles of liberty. But it was the quarrel with the American colonies, commencing 1773 or 4, that called forth the remaining powers of this venerable patriot. He oppoſed with all the powers of eloquence of which he was the maſter, though unfortunately in vain, every harſh and coercive meaſure which haſtened the fatal catastrophe; he made motion after motion for cloſing the breach after it had been effected, and he foretold, with almoſt prophetic accuracy, the final reſult. Such was his anxiety on this ſubject, that it drove him from his bed in the miſt of pain and great debility of body, and urged him to a vehemence beyond that of his beſt years, and at length was the immediate cauſe of his death. On the 7th of April 1778, the duke of Richmond having moved an addreſs to his majesty, on the ſubject of the ſtate of the nation, in which the *necceſſity of admitting the independence of America* was inſinuated, lord Chatham deprecated in the warmeſt terms ſuch a termination as the

the ruin of British greatness. "I rejoice," said his lordship, "that the grave has not closed upon me; that I am still alive to lift my voice against the dismemberment of this ancient and most noble monarchy. Pressed down, as I am, by the hand of infirmity, I am little able to assist my country in this most perilous conjuncture; but, my lords, while I have sense and memory I will never consent to deprive the royal offspring of the house of Brunswick of their fairest inheritance.—Shall this kingdom, that has survived, whole and entire, the Danish depredations, the Scottish inroads, and the Norman conquest; that has stood the threatened invasion of the Spanish armada, now fall prostrate before the house of Bourbon? Surely, my lords, this nation is no longer what it was! Shall a people that seventeen years ago was the terror of the world, now stoop so low as to tell its ancient and inveterate enemy, take all we have, only give us peace? It is impossible." Lord Chatham's plan, at this moment, for conciliation with America was, no doubt, inefficient; the colonists had passed the Rubicon, and in 1778 nothing short of independence would have satisfied them; but the dying earl thought otherwise, and he proposed to make a great impression upon France, to prevent her sending that assistance to the Americans, which he knew the French court had promised; he recommended also a treaty of union with the Americans; and that America should make peace and declare war in concert with Great Britain; that she should hoist the British flag, and use the king's name in her courts of justice; and he imagined that when America saw the impossibility of deriving any assistance from France, the congress would accept of these terms. He hoped thus at once to conquer and conciliate America by making a vigorous impression upon France. He saw that a war with France was unavoidable, and therefore with his usual penetration and ardour he wished instantly to strike the first blow; detesting that procrastination which gave the enemy power, not only of choosing the period of his convenience, but the first scenes of operation. The duke of Richmond having replied to his speech, lord Chatham attempted to rise to answer his grace, but after two or three unsuccessful efforts to stand, he fainted, and fell back in his seat. He was caught in the arms of some of the lords who stood close to him, and was conveyed to an adjoining room, and the house immediately adjourned. From this state of exhaustion he never recovered; he was indeed conveyed to his seat at Hayes in Kent, where he languished till the 11th of May 1778, when he died, in the 70th year of his age, to the sincere regret of every British subject, who had a just sense of human dignity and virtue. His death, rendered peculiarly impressive by the circumstances just referred to, excited general sympathy. Intelligence of his decease being sent to London, colonel Barré, the moment he heard of the fact, hastened to the house of commons, who were then sitting, and communicated the melancholy information. Although the event had been, in some measure, expected for several days, yet the house were affected with the deepest sensibility. Even the adherents of the court joined in the general sorrow, which was apparent in every countenance. The old members indulged a fond remembrance of the energy and melody of his voice; his commanding eye, his graceful action. The new members lamented that they should no more hear the precepts of his experience, nor feel the powers of his eloquence. A deep grief prevailed. The public loss was acknowledged on all sides. Every one bore testimony to the abilities and virtues of the deceased, and on this occasion all appearance of party was extinguished. His remains were honoured with a public funeral; his debts were paid by the nation, and an annuity of 4000*l.* out of the civil list was annexed to the earldom of Chatham. The

sense of the extraordinary merits of this great man was not confined to his own country; it pervaded the whole of Europe, and was attested by some of the highest characters in it. But of all the numerous portraits which have been drawn of him, and of which many are preserved in the "Anecdotes" already referred to, that of lord Chesterfield is the most striking, and probably, upon the whole, the most accurate. "His private life," says the noble writer, "was stained by no vice, nor sullied by any meaness. All his sentiments were liberal and elevated. His ruling passion was an unbounded ambition, which, when supported by great abilities, and crowned with great success, make, what the world calls, a great man. He was haughty, imperious, impatient of contradiction, and overbearing—qualities which too often accompany, but always clog, great ones. He had manners and address; but one might discern through them too great a consciousness of his own superior talents. He was a most agreeable and lively companion in social life, and had such a versatility of wit, that he would adapt it to all sorts of conversation. He had a most happy turn to poetry, but seldom indulged, and seldom avowed it. His eloquence was of every kind, and he excelled in the argumentative as well as in the declamatory way. But his invectives were terrible, and uttered with such energy of diction, and such dignity of action and countenance, that he intimidated those who were the most willing, and the best able to encounter him. Their arms fell out of their hands, and they struck under the ascendant which his genius gained over theirs." Demosthenes was his great model in speaking, and it has been said he translated some of his orations several times over. But though he was delighted with the manner of this orator, who united a wonderful power of expression to the most forcible method of reasoning, yet he was equally master of the pleasing, diffuse and passionate style of the Roman orator.

Of lord Chatham's literary productions, the chief is a volume of "Letters," written to his nephew, afterwards lord Camelford, father of the lord Camelford who was shot a few years since in a duel.

His lordship had five children, *viz.* three sons and two daughters: 1. John, the present earl of Chatham, born in 1756. 2. William, born in 1759, who will be the subject of the following article. 3. James Charles, born in 1761, and who is now dead. 4. Lady Hester, born in 1755, who married the present earl Stanhope, and died in the year 1780: this lady left three daughters, of whom the youngest, lady Lucy Rachel, married Thomas Taylor, esq. and who, to the great grief of all that knew her, died March 1, 1814, having exhibited through, alas! much too short a life, in almost the highest degree, every virtue that could adorn the child, the wife, the mother, and the friend. 5. Lady Harriet, born in 1758, who married the eldest son of lord Eliot, and died in 1786.

PITT, WILLIAM, second son of the preceding, and his successor in political talent and celebrity, was born May 28th, 1759. He was educated at home, under the eye of his father, who at a very early period discovered that in his son were talents that would repay all the attention that could be bestowed on them, and which were likely to raise him to distinction in the country. For the classical education of his son he had a domestic tutor, but he relied entirely upon his own instructions, communicated in conversation, for opening his mind, and giving him a turn to large and accurate enquiry. For the purpose of accustoming him to that facility of speaking, which he felt had been of great importance to his own rise in the world, he frequently made him declaim on given topics. At an age when, with the generality of young people, much remains to be learnt at school, Mr.

Pitt was found fully qualified for the university : and accordingly, as soon as he had completed his fourteenth year, he was entered at Pembroke-hall, Cambridge, and placed under the private tuition of Dr. Prettyman, the present bishop of Lincoln. At college he was distinguished alike for the closeness of his application, and for the success of his efforts, in attaining those branches of knowledge to which his studies were particularly directed. Although no proofs are recorded of extraordinary brilliancy in his academical career, yet few young men of any rank have passed through the probation of an university with a more respectable character for morals, abilities, industry, and regularity. He was intended by his father for the bar and the senate, and his education was regulated so as to embrace both these objects. Soon after he quitted the university, he went to the continent, and passed a short time at Rheims, the capital of Champagne. The death of his illustrious father, while he was in his 19th year, could not fail to cast a cloud over his prospects, but the foundation was laid of those qualities which would enable him to clear the path to eminence by his own exertions. He had already entered himself a student of Lincoln's Inn, and as soon as he was of age, in the year 1780, he was called to the bar, went the western circuit once, and appeared in a few causes as a junior counsel. His success during this short experiment was thought to be such as was amply sufficient to encourage him to pursue his legal career, and to render him almost certain of obtaining all the wealth and honours which await the able and industrious labourers in the vineyard of the law. He was, however, destined to pursue a very different path, to signalize himself as a statesman rather than as a barrister, and to take, for a long series of years, an active part in the regulation of the destinies of his country and the civilized world. At the general election in 1780, he was persuaded to offer himself as a candidate to represent the university of Cambridge, but, upon enquiry, he found his interest would not be equal to carry the election; he therefore wisely declined the contest. Before, however, he had completed his twenty-second year, he was, through the influence of sir James Lowther, returned member of parliament for the borough of Appleby. This was in the month of January 1781, a period in which an opposition, composed of some of the greatest characters in the nation, was in warm contention against the ministry, which, under the guidance of lord North, was carrying on a disastrous war with the American colonies. By this party the power of the crown was regarded as too great for the balance of the constitution, and its reduction by means of certain reforms was the favourite topic of the times. For this purpose Mr. Burke, at the commencement of the session, brought forward his well-known bill for an economical reform in the civil list. It was on this occasion that Mr. Pitt, on the 26th of February, 1781, made his first speech in the British senate. The attention of the house was naturally fixed on the son of the illustrious Chatham, whose memory was still dear to the nation, but in a few moments the regards of the whole audience were directed to the youthful orator on his own account. Unembarrassed by the novelty of the situation in which he had been so lately placed, he delivered himself with an ease, a grace, a richness of expression, a soundness of judgment, a closeness of argument, and a classical accuracy of language, which not only answered, but exceeded, all the expectations which had been formed of him. During the same and the subsequent session, he occasionally rose to give his sentiments on the mal-administration of public affairs, and to prove that he inherited his father's abhorrence of the American war, as well as his liberal ideas on other public topics. What seemed particularly to interest his patriotic feeling, which he unquestionably possessed, at

this time, was a reform of parliament. The necessity of some improvement of this kind had strongly impressed a large proportion of the nation, and meetings of numerous bodies of men had been held in different parts, who had appointed delegates to consider of the best plans for bringing it to effect. In one of these conventions, holden at the Thatched-House tavern, Westminster, Mr. Pitt himself sat as a delegate. It is true that when examined on his oath, in the year 1794, on the trial of Mr. Tooke, he did not seem to remember that he sat as a delegate, though he admitted he had been engaged in attempts to obtain a parliamentary reform, for which, and which only, the prisoner, at the instance chiefly of Mr. Pitt, was then under trial for high treason; but Mr. Sheridan, who was engaged with Mr. Pitt on the same business, expressly declared that the meeting at which they attended was a convention to which delegates were appointed from counties, towns, and different parts, to promote the object of parliamentary reform, and to act, not for themselves individually, but for those who deputed them.

As a public speaker, we have already observed Mr. Pitt had opened his course with great splendour, and it was soon evident to all who acted with him, or who were witnesses to the exercise of his talents, that he was apparently destined to act a high part on the political stage. When, however, lord North's administration broke up, and a new one was formed under the auspices of the marquis of Rockingham, Mr. Pitt was not invited to take a share in it. He still pursued the great object of parliamentary reform, and in May, 1782, moved for a committee, "to enquire into the state of the representation in parliament, and to report to the house their observations thereon." The motion was lost by a majority of twenty. Mr. Pitt did not on this occasion endeavour to discuss the question as to the best species of reform; he only asked for an enquiry, in order that a report might be made to the house as to the best means of carrying into execution a moderate and substantial reform in the representation of the people. On this and two other occasions, *viz.* in May 1783, and April 1785, he supported the necessity of a parliamentary reform with great eloquence, and the most powerful reasoning, after which he abandoned the cause for ever. It has since been ably advocated by alderman Sawbridge, Mr. Flood, Mr. Grey, sir Francis Burdett, and the Hon. Thomas Brand. (See a sketch of various proposals for a constitutional reform in the representation of the people from 1770 to 1812, supposed to be drawn up by Mr. Meadley, author of the lives of Dr. Paley and Algernon Sydney.) The death of the marquis of Rockingham soon put a period to the administration of which that nobleman was the bond of union, and in July 1782, lord Shelburne having, with a part of the former members, placed himself at the head of a new arrangement as first lord of the treasury, associated Mr. Pitt, who had just completed his 23d year, as chancellor of the exchequer: he refused, it was said, to occupy an inferior post. A general peace soon followed, which was made a ground of censure by a very powerful opposition; and in April 1783, the famous coalition ministry took the places of those whom they had expelled. Mr. Pitt, during his continuance in office, had found little opportunity to distinguish himself, otherwise than as an able defender of the measures of administration, and a keen animadverter upon the principles and conduct of his antagonists. He retired with a character unimpeached, and immediately, as we have seen, resumed his efforts for promoting the reform of the representation.

A circumstance soon after occurred, which was the eventual cause not only of Mr. Pitt's return to office, but of his possession of a degree of authority with the king, and of popularity with the nation, which has rarely been the lot

of a minister, and which he preserved, with short interruptions, to the end of his life. A bill for the regulation of the territorial government in India was brought into parliament, in November 1783: the leading provision of which was to vest the whole management of the affairs of the East India Company in seven commissioners named in the act, and of course to be appointed by the existing ministry. It was most violently opposed by Mr. Pitt, on account of its being a violation of the chartered rights of the Company. It nevertheless passed the house of commons by a large majority, and was of course carried from thence to the upper house. In the mean time, an alarm was raised respecting the inordinate power which such a regulation would confer upon the ministry, and which would render them almost, or perhaps altogether, independent of the crown. It was afterwards ascertained, that, in a private audience granted to lord Temple by his majesty, this danger was represented in such a light, that directions were sent to all the noblemen dependent upon, or in confidence with, the court, to vote against the bill; and it was accordingly rejected. The immediate result of this was a change of ministry; and in the new arrangement, in December 1783, Mr. Pitt united in his own person the offices of first lord of the treasury and chancellor of the exchequer; and thus in his 24th year assumed the station of prime minister. Though called to this high station by the voice of the sovereign, he had a most formidable opposition to encounter in the house of commons; and his first India bill was rejected, on the motion for its commitment, by a majority of eight, there being for the motion 214, and against it 222. A spectacle was now presented, which in this country was regarded as very extraordinary, viz. that of a minister standing unmoved, though opposed to the majority of the national representatives; and it was obvious he had but one of two measures to adopt, either to retire from office, or dissolve the parliament. He chose the latter, which took place in the month of March 1784, and of course a general election succeeded. On this occasion, independently of that sort of influence, which, though nameless, is not less efficacious in obtaining a majority, it evidently appeared that the voice of the nation was decidedly in favour of the minister; and he had the singular good fortune of being supported as well by the friends of the royal prerogative, as by those of parliamentary independence, and the new parliament opened with a large majority on the ministerial side. Mr. Pitt, on this occasion, was returned member for the university of Cambridge; and his first measure of great importance in parliament was the passing of his India bill with some alterations: the essence of which was the constituting of a board of controul appointed by the king, out of the privy council, for superintending the civil and military government, the revenue, and concerns of the Company; while their commercial and internal affairs were left to the management of their own directors. The king was to nominate a commander-in-chief, and to possess a negative upon all appointments of the Company; and a new court of judicature was instituted for the trial of offences committed in India. Another important plan, in which he occupied himself, was for the prevention of smuggling; and for this purpose, he, by what was denominated the Commutation Act, took off the principal duties from tea, and supplied the deficiency by a large addition to the window-tax. Through the whole of his career, Mr. Pitt obtained the most general applause as a minister of finance; and the plans which he introduced for the gradual extinction of the national debt, are still operating with great benefit, and have enabled this country to carry on a twenty years' war of unexampled expence. Adopting the principle

of some able writers on political arithmetic, of the vast accumulating powers of compound interest, he introduced, in 1786, a bill, for setting apart a million annually for the purchase of stock, which sum was to be augmented by the interest of the stock so purchased. Perseverance in this plan, with occasional improvements, has already, amidst all the pressure of public burdens, extinguished between two and three hundred millions of debt, and produced a very considerable revenue to be applied to the same purpose. For this plan the financier was indebted to the late excellent Dr. Richard Price, who, on an application from Mr. Pitt, gave him three plans, of which he selected the least efficient; and for this he did not think it worth his while to make the smallest public acknowledgment. (See FUND and PRICE.) Mr. Pitt likewise made various alterations in the mode of collecting taxes, so as to obviate and prevent frauds and defalcations, render them more productive, and come in aid of the great system. A commercial treaty with France, in 1787, founded, as it was understood to be, on reciprocal advantages, and supported upon the liberal principle that neighbouring states, instead of being foes and rivals, might become mutual assistants in the progress to prosperity, exhibited, in a faint degree, the minister's attention to the trading interest. It was soon discovered, that the superior information of the English negotiators threw the benefits of the treaty so much into their own scale, that, upon experience of its effects, it occasioned general dissatisfaction among the merchants in France.

On the question of the impeachment of Mr. Hastings, Mr. Pitt, who seemed ever desirous of following public opinion, voted with the majority in favour of that measure, though most of his colleagues in office inclined to the other side. A similar attention to the prevailing sentiments, perhaps, induced him to act as the champion of the established church, in several applications from the dissenters for the repeal of the Test and Corporation Acts (see TEST); a measure to which it was supposed that a son of the illustrious earl of Chatham would have naturally been inclined. Mr. Pitt entered eagerly into continental politics, and the aggrandisement of Russia, under the empress Catharine, was considered by him as an object for the interference of the English court. He formed leagues to counterbalance her power in the north; and in order to prevent her from retaining possession of the fortrefs of Otchakof, he had nearly involved the two countries in a war. The unpopularity of this measure was soon manifest; his resolution was shaken, and he abandoned the object altogether. He next displayed a readiness to recur to arms, in a dispute with Spain respecting the fur-trade at Nootka sound, which was violently opposed in and out of parliament, and which was at length adjusted by a convention. His interference to preserve the power of the stadtholder in Holland, and defeat the machinations of the French in that country, was a very popular measure.

In the autumn of 1788, the people of England were thrown into a state of alarm, by a calamity which threatened to deprive them of their sovereign. In the beginning of October, his health appeared to be sensibly impaired; and though he was sufficiently recovered to hold a levee on the 24th of that month, before its conclusion the disorder assumed a marked character, and most serious aspect. Early in the ensuing month, it became generally known that it had settled in the brain, and had rendered his majesty incapable of exercising the royal functions. Parliament having been prorogued to the 20th of November, it became necessary that it should meet that day, as the sovereign, by whom only it could be further prorogued, was not in a situa-

ation to assert his prerogative. In the mean time, the leaders of the different parties, who were materially interested in the event, assembled in the capital; and an express was dispatched to Mr. Fox, then absent on the continent, to accelerate his return. This occurrence gave occasion to a display of the firmness and decision of Mr. Pitt's character. In this article we cannot enter into many particulars; but we may observe, that the first material question brought up by this event was, in whom the office of regent was vested? The prince of Wales being connected with the party in opposition, it was contended by them that the regency of course devolved upon him; while, on the other hand, Mr. Pitt supported the doctrine, that it lay in the two remaining branches of the legislature to fill up the office, as they should judge proper; admitting, at the same time, that no other person than the prince could be thought of for the post. By adopting this principle, he carried with him the concurrence as well of those who were attached to the popular part of the constitution, as of the king's friends, whose great object was to secure his return to power, on the cessation of his malady; and he was enabled to pass a bill, greatly restricting the power of the regent, which his majesty's timely recovery in the beginning of the year 1789 rendered abortive. Mr. Pitt was now left to pursue his plans of internal economy, without those interruptions to which he had lately been subjected. He had received, during the discussions on the regency, very decisive tokens of esteem from many of the most respectable public bodies in the kingdom; and he had the satisfaction of knowing, that the firm and steady conduct which he observed, on a question peculiarly calculated to try the firmness, steadiness, and consistency of a public character, had obtained for him, in a very marked manner, the confidence of their majesties, and greatly increased his popularity throughout the nation.

The next great event in which he was to take a leading part was the French revolution, an event the most momentous in its consequences that modern history records. (See REVOLUTION, *French*.) The influence of this vast convulsion could not be viewed by the politician, and the minister of a great empire, but in a double light, as exerted upon France itself, and upon the neighbouring states. Its principles and progress were, without doubt, watched with a jealous and anxious eye by Mr. Pitt, as well as by all others engaged in the service of existing governments. That the tyrannies of Europe, the despotism exercised in the greater and the smaller states, should tremble at the effects likely to be produced by the French revolution, was not a matter of surprise; but the constitution of our own country, if not actually founded, yet built upon the principles of national liberty, had at that moment nothing to dread: and it is not saying too much to affirm, that if the minister had possessed a mind capable of taking advantage of the circumstances as they rose, and kept aloof from war, he might have rendered the continental storms indefinitely useful, in promoting the prosperity of these islands. Had he led those systems of reform, which, but a few years before, he had been eager to propose, and strenuous to vindicate, he would have quieted the voice of discontent, and might have carried the country with him: instead of which, he now pertinaciously clung by those very abuses and corruptions, which he had formerly so successfully exposed, which gave room for invective, and at length excited those clamours, which subsequently required a "vigour beyond the law to suppress." There is scarcely any doubt that Mr. Pitt was, at first, against engaging in the war against France; but finding the majority of the cabinet determined on the project, he gave up his principles rather than retire from the helm of

government. If, however, he were tardy in entering upon hostilities, he made up in zeal for any moments that were lost in discussing the principles of action. The war of England, as well as that carrying on by the allied despots on the continent, was against *French principles*; and in the contest, the government of this country was soon aided by all the great powers and authorities of the nation; by the magistracy, the law, the church, the army, the mass of property hereditary and commercial. In opposition to this, the democratical party, if not very numerous, were actuated by an enthusiastic zeal bordering on madness. The views of the Whigs, headed by a Grey and an Erskine, extended only to such temperate reforms as had been proposed by the minister himself; but there were others, who were perpetually appealing to their country as to the necessity of those more radical changes, which had been vindicated by the duke of Richmond, now an adherent to Mr. Pitt and the court, *viz.* annual parliaments, and universal representation. Some few, but certainly very few in the whole realm, unless actuated by the hope of plunder, went much farther, and anticipated a revolution in this country similar to that in France.

Under such circumstances, a vigilant eye and a steady hand were obviously necessary to steer the vessel of state amidst those dangers. By his own zealous adherents, Mr. Pitt obtained for the time the epithet of "the pilot who weathered the storm;" but the manner in which he exercised the almost unlimited power entrusted to him, will not justify the application of this epithet. He had few of the qualities of a good pilot: he was more eager to engage in the battle, and to hurl the thunder of war, than to direct the motion of the vessel. To sound alarm as loudly as possible through the nation; to encourage the dissemination of high principles of government, and involve in common obloquy all measures of opposition, and all projects of reform; to augment, according to the apparent or pretended urgency of circumstances, the restrictions upon political liberty; and make sacrifices of the spirit of the constitution to what was denominated by the government party, the public safety; appears to have been the system of his domestic policy. For some time he probably had no participation in the plans for interfering in the internal concerns of France, which was the occasion of the first hostilities: for Mr. Pitt, in the year 1792, when laying before parliament a very flattering statement of the national revenue, did not hesitate to prognosticate a long continuance of peace and prosperity. Before, however, the year was closed, the militia was suddenly called out, parliament summoned at the shortest possible notice, and war was eventually declared by this country, by withdrawing our ambassador from the court of France. The deposition and execution of the unfortunate Lewis XVI., added to the circumstances just referred to, rendered the war in which Mr. Pitt engaged extremely popular throughout the nation. At that time, it was imagined the contest would be very short; that the democratic party of France would be destroyed; and either that the Bourbons would, in a few months, be restored, or that the empire itself would be divided among the neighbouring nations. The ill success which attended this confederacy could not certainly be charged upon the want of vigour in the British minister, who entered into it apparently with his whole heart, and lavished all the resources of the country upon its support. In a few months, the direful effects of war were felt over the whole of Europe. The calamities that attached themselves to our own commerce and manufactures, were great beyond example; but they were not peculiar to Britain. Bankruptcies spread over the whole continent of Europe, through

through France, Holland, Germany, Poland, Russia, Italy, and Spain; and almost every where, in the year 1793, private as well as public credit was impaired, if not, for the season, totally destroyed. In one respect England differed, at this crisis of general distress, from most of the other European nations: her public credit was sound, and, by affording a prompt and liberal assistance to her manufacturers and merchants, the difficulties were in a short time overcome. It was in the midst of these calamities, brought on by the prevalence and extension of the war system throughout Europe, that an able writer, and most excellent man, now, alas! no more, thus apostrophised the minister: "If I were bold enough to appreciate your political life, Mr. Pitt, I should be inclined to allow the outset of it extraordinary merit. The sentiment of approbation that attended you was indeed almost universal: you were the hope of the good, the pride of the wise, the idol of your country. If your official career had terminated with the discussions on the regency, it may be questioned whether modern Europe could have produced a politician or an orator more strenuous, more exalted, more authoritative; one whose ambition was apparently more free from selfishness; who afforded to his opponents less room for censure, or gave to his friends more frequent occasions of generous triumph, and honest applause. The errors that you have fallen into are natural for men long possessed of power uncontrolled; and in imputing them to you, I accuse you only of the weaknesses of human nature. It is natural, I believe, for successful ambition to seek new objects on which it may exert itself. Hence, after you had subdued opposition in England, you issued forth, like another Hercules, in quest of new adventures, and traversed the continent of Europe to seek monsters, whom you might subdue. You could not, however, but be sensible that the reputation of a minister of trade and finance, which you had justly obtained, was incompatible with that of a great war minister, in the present state of the nation. You took, therefore, the middle line: you made preparations for fighting on every occasion, but you took care not to strike. England might perhaps bear the expence of arming, but could not actually go to war; and this secret, which your three successive armaments discovered to all Europe, led Mirabeau on his death-bed to give you the name of *ministre preparatif*.

"In men long in possession of power, a secret sympathy, unknown perhaps to themselves, is gradually strengthening in favour of others in the same situation; and a secret prejudice, amounting perhaps at last to enmity, against opposition to power in every person. Hence the danger you saw to England, in the triumph of the patriots of Holland over the prince of Orange; and the safety we acquired from the subjugation of the Dutch by the Prussian arms. Hence also the perfect composure with which you expected the conquest of France, by the despots of Germany; and the sudden alarm with which you were seized, on the repulsion of that invasion, and the over-running of Flanders by the republican arms. By the freedom of Brabant, the constitution of England might be endangered; but it became more secure in your eye, it should seem, by the extension of despotism over every corner of Europe, and the success of foreign bayonets in rooting out liberty, as well as licentiousness in France." Such was the character of Mr. Pitt, drawn in 1793, by the masterly hand of the late Dr. Currie, under the feigned name of Jasper Wilson. Its likeness, after more than twenty years, will not be disputed; and on that account we have transferred it into our columns.

We do not pretend to enter into the details of the war with France, and shall content ourselves with noticing a few

of its consequences. Great Britain, on the whole, was triumphant on her own element; but the contest on the continent went entirely in favour of France, who, at length, united in a confederacy against England some of the powers who had been her allies in the commencement. She was now obliged to attend to her defence at home, and at the same time was pressed by an accumulation of difficulties, which native strength alone could have enabled her to surmount. In 1797, the bank of England was unable to answer the demands made upon it, and an act of parliament was passed to allow the governors of that establishment to suspend their payments in cash, and to substitute for gold and silver, notes of every description, even to those for two pounds and one pound. Another shock to the credit of the country was a daring mutiny of the fleet; and these disasters had scarcely been averted, before a most formidable rebellion in Ireland broke out, and which was not extinguished without the employment of a large military force, and the adoption of such sanguinary measures as were disgraceful to those who resorted to them. The public burthens went on accumulating in a vast ratio, and Mr. Pitt was obliged to have recourse to a triple assessment, and finally to an income tax, for raising the necessary supplies. In 1799, he, with the aid of pecuniary offers, produced a new confederacy, in which the numerous armies of Russia and Austria were employed to overthrow the preponderancy of France, but its final issue was completely unfortunate. In the following year Mr. Pitt had brought to effect the great and arduous measure of an union between Great Britain and Ireland, a measure, the true policy of which has long since been generally acknowledged. The war with France was now become so hopeless with regard to any object with which it might have commenced, and the nation was so completely wearied with protracted hostilities, that Mr. Pitt, aware that he could make no peace correspondent to his high language, resolved to quit the important station he had so long occupied. He resigned his post in February 1801, and was succeeded by Mr. Addington, now lord Sidmouth. The peace of Amiens soon followed, which Mr. Pitt defended in his place in parliament. He afterward, in some important points, joined the opposition, and the new minister was in a short time forced into a second French war. His talents were soon found unequal to the contest in which he had embarked, and Mr. Pitt, in 1804, resumed his post as first lord of the treasury, at the head of an arrangement formed of part of the ministers then in place, with the addition of some of his own friends. He now came into office as a war minister, and exerted all the vigour of his character to render the contest successful. He engaged the two great military powers of Russia and Austria in a new confederacy against France. The errors committed by them in their plan of co-operations were fatal to the cause, and the battle of Austerlitz put an end to the hopes of a check to the then enormous aggrandizement of an empire which seemed destined to sway the European continent. Mr. Pitt was in a state of health ill calculated to meet this terrible stroke. He had, from an early period of life, given indications of inheriting his father's gouty constitution, with his talents, and it had been thought necessary to make the liberal use of wine a part of his ordinary regimen. The habit and the necessity, of course, gained ground upon him, and he did not escape the charge of convivial intemperance. This abuse of strong stimulants, added to the cares and exertions of office during the stormy period of his administration, brought on a premature exhaustion of the vital powers. In December 1805, he was recommended to go to Bath, but the change afforded him no permanent relief. On

the 11th of January he returned to his seat at Putney, in so debilitated a state, as to require four days for the performance of the journey. The physicians, even yet, saw no danger, and they said there was no disease, but great weakness, in consequence of an attack of the gout. On the following Sunday he appeared better, and entered upon some points of public business with his colleagues in office: the subject was supposed to relate to the dissolution of the new confederacy, by the peace of Presburgh, which greatly agitated him. On the 17th, at a consultation of his physicians, it was agreed, that though it was not advisable he should attend to business for the next two months, yet there was hope he would be able to take a part in the house of commons in the course of the winter. On the 20th, however, he grew much worse, and it was admitted his situation was precarious; in other words, those who till then had encouraged hope in the patient, now saw that he was in the most imminent danger, and that, probably, he had not many hours to live. The bishop of Lincoln, who never left him during his illness, informed him of the opinion now entertained by sir Walter Farquhar, and requested to administer to him the consolations of religion. Mr. Pitt asked sir Walter, who stood near his bed, "How long do you think I have to live?" The physician answered that he could not say, at the same time he expressed a faint hope of his recovery. A half smile on the patient's countenance shewed that he placed this language to its true account. In answer to the bishop's request to pray with him, Mr. Pitt replied, "I fear I have, like too many other men, neglected prayer too much, to have any ground for hope that it can be efficacious on a death-bed—but," making an effort to rise as he spoke, "I throw myself entirely on the mercy of God." The bishop then read the prayers, and Mr. Pitt appeared to join in them with a calm and humble piety. He desired that the arrangement of his papers and the settlement of his affairs might be left to his brother and the bishop of Lincoln. Adverting to his nieces, the daughters of earl Stanhope by his elder sister, for whom he had manifested the sincerest affection, he said, "I could wish a thousand or fifteen hundred a-year to be given them; if the public should think my long services deserving of it." He expressed also much anxiety respecting major Stanhope, that youthful hero, who fell a sacrifice to his valour at Corunna, in company with his friend and patron general sir John Moore, and his brother, who was also at Corunna at the same time, and who has been engaged in all the great battles in the peninsula, and more than once severely wounded in his country's service. Mr. Pitt died about four o'clock in the morning of the 23d of January 1806, in the 47th year of his age. A public funeral was decreed to his honour by parliament, and 40,000*l.* to pay those debts which he had incurred in his country's service. Public monuments have been since erected to his memory in Westminster-Abbey, in the Guildhall of the city of London, and by many public bodies in different parts of the kingdom. There is no doubt that he died in possession of the esteem and attachment of a large portion of his countrymen, and his political consequence was proved by the entire dissolution, at his death, of the ministry of which he was the head, and the necessary admission of a party, against whom strong prejudices were known to prevail. He will long live in memory as a distinguished orator, an able financier, and a man of uncommon talents: whether he is also to be ranked among great and enlightened statesmen, impartial history will hereafter decide. Dr. Stock, in his interesting life of Dr. Beddoes, speaking of the "Essays

on the public Services of Mr. Pitt," says, "But we are as yet too near the time of action to examine, with equal impartiality, the merits of writings so hostile to Mr. Pitt. A great portion, however, of the events anticipated in these essays, is already become history. The career of this celebrated statesman is closed. If his measures were good, he can no longer direct; if bad, he can no longer restrain their influence. A long period must elapse, perhaps it must be left to distant posterity, to trace their full influence on the destinies of Great Britain. The censure which the author (Dr. Beddoes), has thrown upon his plans may be unjust, but his anticipation of their failure was prophetic. Principles were in action, the full operation of which had not been familiar to human experience. Common political calculations, and common-place statesmen, were every where baffled and confounded. But however deplorably his schemes of foreign policy may have failed, whether from deficiency in political sagacity, or from incapacity or treachery of allies; his advocates will triumphantly maintain that, in point of primary importance, he succeeded: he saved the English constitution. If this be true, no praise can exceed his deserts, and no honours that a grateful nation can pay to his memory can be excessive. To have preserved a constitution, which has raised man to the true level of his nature, which has ripened souls, which secures to every individual under its protection a degree of practical liberty of writing, of speaking, and of action, greater than exists in any country on the surface of the globe, must emblazon his name to all posterity. Should all the other pillars that support the temple of his fame give way, so long as this remained unshaken, it would, singly, uphold the fabric. His opponents will, however, remind us of unhallowed attempts to deprive us of these proud distinctions; and they will contend, that great as are the honours that should be paid to his memory, if the measures of his administration should appear to have been really the means of preserving this glorious monument of the wisdom of our ancestors; so great must be the indignation that should pursue it, if they should have proved to have impaired its magnificence, to have undermined its foundations, and to have exposed us to the hazard of a contest, in which not common interests only are involved, but on the issue of which is staked every thing that is dear to the heart of a Briton, every thing that can render life itself valuable and desirable."

It is not easy to understand what is meant by the word Constitution: if by it is intended simply the government by King, Lords, and Commons, Mr. Pitt found such a government, and left it as safe as he found it; but it would be difficult to prove that it ever was in danger: in the very worst period,—in the years 1793 and 4,—it may be doubted, if in the whole extent of Great Britain, there could have been found a thousand persons, who would, whatever were their motives, have wished for any change in this respect; and hence no great merit can be given to Mr. Pitt as the favourer of our mixed form of government. If, however, by the Constitution are intended those guards and that security of the people, which are essential to their existence as a free nation, it would not be easy to shew in what respect Mr. Pitt was the favourer of the Constitution. The securities to which we have referred, and which, in the estimation of Blackstone and all our great constitutional lawyers, have been regarded as the fundamentals of our excellent constitution, are *Magna Charta*, the *Habeas Corpus Act*, the *Liberty of the Press*, and *Trial by Jury*. If these exist in a country, the people have a pure and a perfect constitution; they need no more to render them, in every just sense of

the word, a free people. *Magna Charta* declares, that no man shall be imprisoned contrary to law: during Mr. Pitt's administration, many persons were thrown into dungeons, in defiance of this wholesome provision of our ancestors. The *Habeas Corpus Act* affords an additional security from false and unjust imprisonment, and points out effectual means, for a person thus maltreated, as well to release himself, though committed by the king in council, as to punish all those who shall thus unconstitutionally misuse their power. Mr. Pitt not only suspended the operation of the *Habeas Corpus Act* more frequently than any former minister, and that often without a show of reason, but at length bargained with his successor for an act of indemnity for all his unconstitutional acts, so that the persons thus injured in their fortune, their health, and fair fame, were prevented from seeking pecuniary redress by the law of the land. (See Woodfall's *Parl. Deb.* 1801. vol. ii.) The liberty of the press had not for a century and more been under such shackles as it was during the administration of Mr. Pitt, and by certain bills brought into parliament, and passed into laws by his influence and that of lord Grenville, the tongue was fettered, and the Bill of Rights made nugatory. In one of Mr. Pitt's treason bills, he endeavoured to contract those advantages which the statute of Edward III. allows to the accused, by granting them less time than ten days to enquire into the characters of those who were to try, and those who were to be brought as witnesses against them. When, however, he found the House determined to resist the innovation, he triumphantly said, that "Nothing was more easy than utterly to defeat that wise and humane law, by sending to the men accused a *cloud* of witnesses," to perplex and confound them. In 1794, what he had said *might* be done, *was* done, and he was still prime minister. On the memorable state trials, each prisoner had more than 200 persons nominated as jurymen to try him, and the names of 213 persons were given him, as those who might be produced as witnesses in the cause. Hence the *trial by jury* was invaded in one of the most important cases that ever arrested the public attention. This, however, was but a sequel to his general conduct; he had extended the Excise and Custom-house laws beyond all former precedent; and in many of his fiscal regulations, he utterly discarded the idea of the intervention of a jury between the king and the subject. In a hundred of his acts, the magistrate is also made paramount to all law, and it requires but the evidence of a common thief-taker to deprive a subject of his liberty. Cases of this kind are not rare; scarcely a month or even a week occurs, but the public papers announce, that persons are committed to prison for three or six months by the order of a police magistrate, who is guided in his decision only by the oath of a man, perhaps much worse than he who is subjected to the punishment.

We may, indeed, proceed one step farther, and say, that notwithstanding the early tincture which Mr. Pitt's mind may be supposed to have received in favour of freedom and those principles, which we have assumed, on good authority, as the bulwarks of the British constitution, and the voluminous additions which he made to our acts of parliament, it will be difficult to find a single disinterested law introduced by him in favour of the liberty of the subject, within the whole compass of our statute books. This fact, if it be a fact, must not be imputed to the spirit of the times; in the early periods of the present reign, toleration and religious liberty received some important accessions; and since the death of Mr. Pitt, she has, under the auspices of the present administration, been still better treated, and

a wider scope has been given to speculative enquiry. That all improvement in civil and religious liberty should have ceased during the twenty years of Mr. Pitt's ministry, cannot be accounted for if he had been, in office, what he unquestionably was when he first entered upon public life, an ardent friend to the liberties of his country. We should gladly give, if authorities would support us, some traits of a different kind to justify the epithet of his friends applied to him as the favourer of the constitution. With this view, we have looked through the voluminous History of Mr. Pitt's Political Life by Mr. Gifford; but in all the six volumes nothing cheering, nothing favourable appears. As a private character, he was, we believe, every thing that was excellent and amiable; to this, and to his character as a man of real talent, we shall turn, and with that estimate shall conclude our article.

Mr. Pitt possessed no particular advantages of person or physiognomy, the first of which was ungraceful, the second repulsive rather than attractive. As a speaker he was thought to be without a rival: such was the happy choice of his words, the judicious arrangement of his subject, and the fascinating effect of a perennial eloquence, that his wonderful powers were acknowledged even by those who happened to be prepossessed against his arguments. When employed in a good cause he was irresistible; and in a bad one he could dazzle the judgment, lead the imagination captive, and seduce the heart, even while the mind remained firm and unconvinced. Ambition and the love of power were his ruling passions; his mind was elevated above the meanness of avarice. His personal integrity was unimpeached, and so far was he from making use of his opportunities to acquire wealth, that he died involved in debts, which negligence, and the demands of his public station, rather than extravagance, had obliged him to contract; for his tastes were simple, and he does not appear to have had a fondness for splendour or parade. His private character has been drawn by a friend, and it corresponds perfectly with other accounts that we have had from those much in his confidence, and who were frequently in his company at times, when the man and not the minister was displayed in all its native colours: "With a manner somewhat reserved and distant in what might be termed his public department, no man was ever better qualified to gain, or more successful in fixing, the attachment of his friends, than Mr. Pitt. They saw all the powerful energies of his character softened into the most perfect complacency and sweetness of disposition in the circles of private life, the pleasures of which no one more cheerfully enjoyed, or more agreeably promoted, when the paramount duties he conceived himself to owe the public, admitted of his mixing in them. That indignant severity with which he met and subdued what he considered unfounded opposition; that keenness of sarcasm with which he expelled and withered, as it might be said, the powers of most of his assailants in debate, were exchanged in the society of his intimate friends for a kindness of heart, a gentleness of demeanour, and a playfulness of good humour, which no one ever witnessed without interest, or participated without delight." See Rose's Examination into the Increase of the Revenue, &c. during the Administration of the Right Hon. William Pitt. See also *Monthly Mag.* vol. xxi. *Wyvill's Political Papers.* *Stock's Life of Dr. Beddoes.* *General Biog.* *New Ann. Regift.* and *Parliamentary Debates.*

PITT, in *Geography*, a county of America, in North Carolina, containing 9169 inhabitants.—Also, a township of Allegany county, Pennsylvania, containing 2441 inhabitants.

PITT Island, an island in the North Pacific ocean, near the W. coast of North America, between Norfolk sound and Salisbury sound, about 50 miles long and 13 broad. N. lat. $57^{\circ} 20'$.—Also, a small island in the Chinese sea. N. lat. $10^{\circ} 57'$. E. long. $114^{\circ} 36'$.

PITT's Archipelago, a range of islands in the North Pacific ocean, extending along the west coast of North America, about 60 miles in length; so called by captain Vancouver in honour of the Rt. Hon. William Pitt. N. lat. $54^{\circ} 10'$. W. long. $52^{\circ} 15'$.

PITTACIUM, *Pittacium*, in *Surgery*, a name which some authors give to a piece of cloth spread with a salve, to be laid on a part affected.

PITTACUS, in *Biography*, a warrior and philosopher, reckoned among the seven sages of Greece, was born at Mitylene, in Lesbos, about the year 650 B.C. In a war between his countrymen and the Athenians, he challenged to combat their general Phrymon, a man of great strength, who had been a victor in the Olympic games, and vanquished him by means of a concealed net, which he threw over the enemy's head. As a reward for his valour he was offered a very large tract of land, which he had recovered from the enemy, but he would accept no more than he could measure by a single cast of the javelin, and of this even he consecrated half to Apollo. He afterwards expelled the tyrant Melanchrus from Mitylene; and having liberated his country, was placed by his fellow citizens at its head. He now governed with as much wisdom as he had fought with bravery. He enacted many useful laws, and in order that they might be the better remembered he comprehended them in 600 verses. In one of these he gave a severe check to the propensity of the people to drunkenness, by enjoining a double punishment for crimes committed in that state. After having held the reins of government during ten years with high reputation, he resigned his authority, and spent the remainder of his life in study and retirement. He died about the year 570 B.C. The maxims of Pittacus were held in such high esteem, that many of them were inscribed upon the walls of the temple of Delphi. The following may be given as specimens of them: "Power discovers the man;" "Whatever you do, do it well;" "Be watchful for opportunities." Enfield's Hist. Phil.

PITTANCE, from *pittantia*, a small coin of Poictou, see Du Cange; a small portion of food, or *entremet*, in opposition to *generale*, or a solid dish, the mention of which pittance frequently occurs in the constitutions of our ancient communities, where they determine how many *generalia* and how many *pittantia* shall be served up on such and such days. These pittances, from whence our present word pittance is derived, usually consisted of plates of legumes, cheese, or fruit.

PITTARO, in *Geography*, a mountain of Calabria Ultra; 14 miles N.W. of Bova.

PITTEN, a town of Austria; 8 miles S. of Ebenfurth.

PITTENWEEM, a royal borough and sea-port town, is situated in the district of St. Andrew's, and the south-east coast of the county of Fife, Scotland. It was formerly a place of considerable trade, but there is now few shipping here. The coal and salt-works, however, still occasion some little activity here and in the adjacent villages. Pittenweem was first constituted a royal borough by king James V. in 1547; and now enjoys the privilege, in conjunction with Crail, of sending one member to the imperial parliament. In the rebellion in the seventeenth century this town suffered greatly, upwards of thirteen sail of vessels belonging to the port having been destroyed or taken by the enemy in the course of two or three years. Here are

some remains of an ancient priory for canons regular of the order of St. Augustine, which was dedicated to the Virgin Mary, and was a cell to the mitred abbey of St. Andrew's. This priory had large landed possessions, together with the churches of Rhind, Anstruther Wester, &c., which are now erected into a regality called the regality of Pittenweem, under the jurisdiction of lairds of Anstruther as heritable bailies. About half-way between the ruins and the beach is a great cave, or weem, whence the borough derives its name. It consists of two spacious apartments, at the junction of which is a stair leading to a subterraneous passage, which formerly communicated with the monastery, but which has long been blocked up by the earth falling in. There is also another stair still remaining, which leads from the refectory to the further extremity of this passage.

Pittenweem, with respect to church government, is in the presbytery of St. Andrew's and synod of Fife. It is distant about $33\frac{1}{2}$ miles N.E. by N. from Edinburgh; and according to the parliamentary returns of 1811, contains 194 houses and 1096 inhabitants. The late learned John Douglas, D.D., lord bishop of Salisbury, was a native of this town. His lordship is well known in the literary world as the vindicator of Milton, from the charge of plagiarism brought against him by Lauder. He was one of the trustees of the British Museum, and co-vice-president of the Society of Antiquaries in London. Carlisle's Topographical Dictionary of Wales, vol. ii. 4to. Beauties of Scotland, vol. iv.

PITTERSBERG, a town of the duchy of Carinthia; 3 miles N. of Mauter.

PITTI, a small island in the straits of Malacca, N. lat. 2° . E. long. $101^{\circ} 29'$.

PITTONIA, in *Botany*, so named by Plumier, in honour of his great countryman and contemporary, Joseph Pitton de Tournefort. (See *TOURNEFORTIA*.) Linnæus, according to the rule he had laid down, preferred the latter appellation, as derived from the name by which the person commemorated was universally known, out of his own country; and the example has been followed by all following writers, even in France; at least in this instance. In some cases there has been a contrariety of opinion. (See *LOUICHEA* and *FONTANESIA*.) Such difficulties are for the future removed, by the simplification of French surnames, since the revolution.

PITTOSPORUM, so named by sir Joseph Banks, according to Gärtner. The word is derived from *πιττωω*, to besmear with pitch, and *σπυρα*, seed or offspring; because the seeds are enveloped in a pitchy fluid, exuding internally from the capsule as it ripens; a circumstance altogether peculiar, thus happily expressed in the generic name.—Gärtner. v. 1. 286. t. 59. Schreb. 150. Willd. Sp. Pl. v. 1. 1145. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 27. Lamarck Dict. v. 5. 361. Illustr. t. 143.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumoseæ*, Linn. *Rhamni*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five, generally very deep, acute, equal segments, deciduous. *Cor.* Petals five, inserted into the receptacle, alternate with the segments of the calyx, oblong, equal; their claws longer than the calyx, linear, channelled, erect, converging in the form of a tube; border ovate-oblong, spreading, recurved. *Stam.* Filaments five, inserted into the receptacle, alternate with the petals, the length of the claws, linear, compressed; anthers incumbent, arrow-shaped, simple. *Pist.* Germen superior, roundish; style awl-shaped, the length of the stamens; stigma obtuse. *Peric.* Capsule roundish, angular, pointed, of from two to five cells and as many

many valves, the partitions from the middle of each valve. *Seeds* three or four in each cell, angular, inserted into the inner edges of the partitions, enveloped in a resinous fluid produced by the inside of the valves.

Eff. Ch. Calyx five-cleft, deciduous. Petals five, converging into a tube. Capsule of several cells and as many valves. Seeds enveloped in a liquid resin.

1. *P. coriaceum*. Thick-leaved Pitch-feed. Ait. n. 1. Willd. n. 1. Vahl Symb. v. 2. 43. Andr. Repof. t. 151. —Leaves obovate, obtuse, coriaceous, very smooth. Capsules of two valves.—Native of Madeira. A greenhouse shrub, flowering in May, said to have been first raised by Messrs. Lee and Kennedy, about the year 1783. The stem is six or eight feet high, bushy, with round, finely downy, branches, leafy at their summits. Leaves crowded, alternate, two or three inches long, remarkably coriaceous, of a fine green, smooth and even, not shining, with one rib, and numerous scarcely visible transverse veins. Footstalks short, broad, channelled, downy when young. Stipulas large, broad, solitary, withinside of the footstalks. Flowers several, in terminal bracteated umbels, with downy stalks, white, powerfully fragrant, like Jasmine, but of short duration. Calyx divided to the very base, and finally falling off in separate portions. Petals obovate, obtuse, recurved, scarcely revolute. Germen elliptic-oblong. Capsule said to have only two valves, a point we have had no means of determining.

2. *P. Tobira*. Glossy-leaved Pitch-feed. Ait. n. 2. Sims in Curt. Mag. t. 1396. (Euonymus Tobira; Thunb. Jap. 99. Willd. Sp. Pl. v. 1. 1130. Tobira; Kämpf. Am. Exot. 796. t. 797.)—Leaves obovate, obtuse, coriaceous, very smooth and shining. Capsules of three valves.—Native of Japan. Brought by an India ship from China to Kew, in 1804, where it flowers abundantly in summer, being a hardy greenhouse shrub. This is so like the foregoing, that it is not easy to discern a specific difference between them. The leaves of the *Tobira* however are of a more shining and darker green above; pale beneath. Capsule, on a specimen from Kew, triangular, and of course having three valves. Flower-stalks and germen very hairy, as in the *coriaceum*, though none of the figures of either give the least indication of such a circumstance. Kämpfer's plate shews the inflorescence to be somewhat racemose.

3. *P. revolutum*. Downy-leaved Pitch-feed. Ait. n. 3. —“Leaves elliptical, bluntish; downy beneath; revolute at the margin.”—Native of New South Wales. Sent by Sir Joseph Banks to Kew, in 1795. It flowers from March to August, and is a greenhouse shrub, like the two above described. We have two specimens from Port Jackson, answering to the character we have copied, except that the leaves are acute, and indeed pointed, in both. The flowers in one grow five or six together, in a stalked hairy umbel; in the other they stand in pairs, on very short stalks, which at length become thick and woody, supporting a large woody capsule, of three reflexed valves, whose partitions are but slightly prominent. These specimens appear to constitute different species, and probably will be better explained in the sequel of Mr. Brown's Prodromus.

4. *P. ferrugineum*. Rusty Pitch-feed. Ait. n. 4. (Cortex filarius; Rumph. Amboin. v. 7. 13. t. 7.—Leaves elliptical, taper-pointed, smooth. Footstalks clothed with rusty down. Calyx equally divided to the base.—We received specimens of this, in March 1789, from Mr. Hoy at Sion-house. It is said in Hort. Kew. to be a native of Guinea, and to have been introduced before 1787, by the earl of Tankerville, flowering in the stove from February to May.

We are possessed of fine specimens of this very plant, gathered by the late Mr. Christopher Smith in Oma, one of the Molucca isles, near Amboyna, but without any mention of its name or properties. Cortex filarius of Rumphius appears to be the same thing. The author never saw the flowers, but his representation and description of the bivalve fruit exactly answers to the genus before us. He speaks of the bark as affording a sort of thread. Of this indeed we can observe no signs, in our dried specimens, but every other part of his description agrees exactly. The stem is shrubby, rather slender, determinately branched; young branches round, clothed with rusty down, leafy towards the ends. Leaves scattered or crowded, elliptic-lanceolate, pointed at each end, two or three inches long, entire, slightly wavy, with one rib and several transverse veins ending in minute reticulations; smooth on both sides, except an occasional pubescence on the ribs; paler and more opaque beneath. Footstalks three-quarters of an inch long, slender, channelled, clothed with fine, shining, rusty down. Flowers very numerous, small, white, in long-stalked, aggregate, rusty, downy umbels. Calyx almost smooth, in five deep, awl-pointed, recurved segments, not so speedily deciduous as in some other species. Petals folded spirally over each other in the bud; recurved when expanded. Anthers obtuse. Germen very hairy. Style short. Stigma capitate. We have seen nothing of the fruit, or even the enlarged germen.

5. *P. undulatum*. Wave-leaved Pitch-feed. Ait. n. 5. Venten. Jard. de Cels, t. 76. Andr. Repof. t. 383.—Leaves elliptical, pointed, smooth; waved at the margin. Footstalks nearly smooth. Calyx five-toothed, split on one side to the base.—Native of New South Wales. Communicated to Kew garden, in 1789, by Sir J. Banks. A greenhouse shrub, flowering from April to June. Its habit is very much like the last, but every part is larger. The leaves are more wavy; their adult footstalks smooth, though downy when young. Flowers white, fragrant, full twice as large as those of *P. ferrugineum*, but much fewer, in solitary, nearly simple, sessile umbels, whose stalks are nearly smooth. Calyx essentially different, being divided only one-third of its length into five acute segments, though split down to the base at one side, sometimes in two places; one tooth, in the latter case, being entirely separate to the bottom. The whole calyx soon falls off. Its inside and edges are a little downy. Ventenat's account of the inflorescence differs from our's, but we find some parts of our specimens have, as he says, three-flowered stalks. He errs in giving the Canary islands as the native country of this species, confounding its history with that of the *coriaceum*. What Gærtner has described, under the names of *tenuifolium* and *umbellatum*, are probably distinct from all the above, or he would have been cited in Hort. Kew. As he gives no specific characters, we can form no just idea of these species. Possibly his *tenuifolium* may be our *undulatum*. Here again we must recur to Mr. Brown's future communications, in the long-expected continuation of his work.

PITQUOTTING, in *Geography*, an Indian settlement in the state of Ohio, at the mouth of Huron river, which discharges itself into lake Erie.

PITTSBOROUGH, or PITTSBURG, a town of America, the capital of Chatham county, North Carolina, situated on an eminence, and containing a court-house, a gaol, and about 40 or 50 houses. The adjacent country is fertile and well cultivated; and is much resorted to from the maritime parts of the state in the sickly months. The Hickory mountain is not far distant, and both the air and water are here

here as pure as any in the world; 26 miles S.W. of Hillsborough.

PITTSBURG, a post-town of Pennsylvania, the capital of Alleghany county, situated on a beautiful plain terminating in a point, between the Alleghany and Monongahela rivers; and about a quarter of a mile above their confluence, by which they form the Ohio. This town was laid out on Penn's plan in the year 1765. It contains between 200 and 300 houses, 4768 inhabitants, a gaol, court-house, Presbyterian church, a church for German Lutherans, an academy, a brewery, and a distillery. It has been lately fortified, and a party of troops has been stationed in it. The hills on the Monongahela side are very high, extend down the Ohio, and abound with coals. Before the revolution one of these coal hills took fire and continued burning for eight years; when it was effectually extinguished by part of the hill giving way and filling up the cavity. The situation, in the midst of hills covered with trees, is delightful. At the distance of 100 miles up the Alleghany is a small creek, which in some places boils or bubbles forth, like the waters of the Hell Gate in the state of New York, from which proceeds an oily substance, deemed by the people of the country an infallible cure for weakness in the stomach, rheumatic pains, sore breasts in women, bruises, &c. The oil is collected and brought to Pittsburg for sale. The navigation of the Ohio, in a dry season, is rather troublesome from Pittsburg to the Miesse town, about 15 miles; but from thence to the Mississippi there is always water sufficient for barges carrying from 100 to 200 tons burden; 393 miles W. by N. from Philadelphia. This town is a thoroughfare for the incredible number of travellers from the eastern and middle states to the settlements on the Ohio; and is very rapidly increasing. At or near this place ship-building is an object of great attention. It was formerly in the hands of the French, and then called Fort du Quebec, afterwards fort Pitt, in honour of the late lord Chatham. General Braddock, advancing at the head of British troops to take it in 1756, fell in an ambuscade and was killed; 4 miles from Pittsburg. N. lat. $48^{\circ} 31' 44''$. W. long $80^{\circ} 8'$.—Also, a township of America, in Frontiac county, Upper Canada, adjoining to Kingston, and here opening westward to lake Ontario.

PITTSFIELD, a pleasant post-town of Massachusetts, in Berkshire; 6 miles N. of Lenox. This township, and also those N. and S. of it, are situated in a rich vale from one to seven miles wide, on the banks of Housatonic river. It was incorporated in 1761, and contains 2665 inhabitants.—Also, a township of Rockingham county, New Hampshire, incorporated in 1782, and containing 1050 inhabitants.—Also, the north-easternmost township of Rutland county, Vermont, containing 338 inhabitants.—Also, a town in Otsego county, New York; 12 miles W.S.W. of Cooperstown.

PITTSFORD, a town of America, in Rutland county, Vermont, containing 1936 inhabitants.

PITTSBOROUGH, a town of America, in the county of Salem, New Jersey, containing 1991 inhabitants.

PITTSSTON, a town of America, in the county of Kennebec, and district of Maine, containing 1018 inhabitants.

PITTSSTOWN, a post-town of Hunterdon county, New Jersey; 58 miles N.N.E. of Philadelphia.—Also, a township of Rensselaer county, New York.—Also, a post-town in Luzerne county, Pennsylvania.

PITTSYLVANIA, a county of Virginia, containing, in 1810, 17,172 inhabitants. At the court house is a post-office, 300 miles from Washington.

PITTY, the most westerly of the mouths of the river

Indus, which separates it from the Darroway, 50 miles below Tatta, and runs into the sea, N. lat. $24^{\circ} 42'$. E. long. $66^{\circ} 22'$.

PITUINA, in the *Materia Medica*, a name for the resin of the pitch-tree.

PITUITA, in *Medicine*, is the same with the Latin writers, as the *phlegma* of the Greeks. See **PILLEGM**.

PITUITARY GLAND, in *Anatomy*, called also hypophysis; a small body lodged in the sella Turcica of the sphenoid bone, and connected to the basis of the brain. See **BRAIN**.

PITUITARY Membrane, is the lining of the nasal cavities. See **NOSE**.

PITUITARY Sinuses, are the hollows in the body of the sphenoid bone communicating with the nose. See **CRAanium**.

PITUM HOTUN, in *Geography*, a town of Chinese Tartary; 438 miles E. of Peking. N. lat. $40^{\circ} 18'$. E. long. $125^{\circ} 21'$.

PITUMBA, in *Botany*, a word that occurs in Schreber's index, and, by his reference, seems synonymous with his *Wolfia*, under which however it is not mentioned. Those who are fortunate enough to meet with it in any book, may perhaps by that means discover what *Wolfia* is, of which we profess ourselves ignorant.

PITY, in *Ethics*. See **COMPASSION**.

PITYCIA, in *Ancient Geography*, an island of the Adriatic sea, on the coast of Liburnia.

PITYDES, a name used by some authors for the kernels inclosed in the cones of the fir or pitch-tree; they are recommended by the old physicians in disorders of the breast.

PITYLISMA, a name of one of the exercises described by the ancient physicians, as of great service in chronic cases. It consisted in a person's walking on tip-toe, and stretching his hands as high above his head as he could, keeping the whole body also as much upon the stretch as might be. In this condition the patient was to walk as far as he was well able, all the while moving about both hands as much as he could, in all directions.

PITYNERA METROPOLIS, in *Ancient Geography*, the ancient Golconda on the right bank of the river Nerva, a town of India, in the interior of the peninsula on this side of the Ganges, according to Ptolemy, who makes it the capital of the people called "Mefoles." On the map of M. d'Anville, it is placed on a river, which runs towards the S.W. into the Mefolus.

PITYONESUS, an island on the coast of the Peloponnesus, six miles from the continent, over-against Epidaurus.

PITYRIASIS, $\pi\tau\upsilon\rho\iota\alpha\sigma\iota\varsigma$, in *Medicine*, from $\pi\tau\upsilon\rho\omega\varsigma$, *furfur*, bran, a slight scaly or scurfy affection of the skin; appearing in irregular patches, sometimes with, and sometimes without, slight redness or inflammation, upon which small thin scales repeatedly form and separate; but they never collect into crusts, and are not accompanied by excoriations.

Such is the character of this cutaneous affection, as pointed out by Dr. Willan, in contradistinction from the other scaly diseases of the skin, lepra, and psoriasis. The Greek writers have not precisely agreed in their acceptation of the word pityriasis. Galen, Aëtius, and Oribasius, speak of it as affecting the head only; Alexander of Tralles, however, and Paul of Ægina, the ablest of the later Greeks, have described the disorder generally, as consisting of "slight scaly and branny exfoliations, without ulceration." All the translators of the Greek writings into
Latia

Latin have rendered the word pityriasis by *porrigo*; not observing that the best Roman authority, Celsus, included under the term "porrigo" not only the *pityriasis*, but the *ceria* and *achores* of the Greeks. As, however, the *porrigo* is a contagious disease, Dr. Willan justly deemed it expedient to separate the non-contagious pityriasis from it, and included only the *ceria* (or *favi*) and *achores* under the former term. See PORRIGO.

Of this slight and non-contagious eruption, three or four varieties have been noticed. The *first* is the *pityriasis capitis*, or *dandriff* (as it is called by the nurses) of infants. This affection shews itself in a slight whitish scurf along the top of the forehead and temples, but in larger, flat, separate, semi-transparent scales on the occiput. A similar affection sometimes occurs on the scalp of aged persons. With a view to cure this form of the eruption, it is only necessary to enforce a regular ablution of the scalp with soap and water, or with an alkaline or weak spirituous lotion; for which purpose the hair must be removed, if it be not thin.

The *second* species, or *pityriasis rubra*, occurs most frequently in adult or even advanced life, and is the result of a slight inflammation of the portions of the skin affected. The cuticle is at first only red and rough, but soon becomes mealy or scurfy, and exfoliates, leaving a simular red cuticle underneath, which undergoes the like process; and as the exfoliation is repeated, the scabiness is augmented. This complaint is attended with a dry and unperpiring state of the skin, and with a troublesome itching, and a feeling of stiffness. When the redness and scales disappear, the patches are left of a yellowish or fallow hue; but the whole process is apt to be repeated at short intervals, and the disease to be thus greatly prolonged. It is sometimes accompanied with a general languor and restlessness. This form of pityriasis is removed by the decoctions of sarsaparilla, elm-bark, &c. combined with antimonials, and with the use of the warm salt-water baths.

The *third* form, or *pityriasis versicolor*, is not uncommon in adult persons of both sexes, and is most remarkable for the chequered and variegated discoloration of the skin which accompanies it. It occurs mostly about the breast and pit of the stomach, and sometimes on the arms and shoulders, in brown patches of different shades, variously branching and coalescing, and interspersed with portions of the natural hue. There is generally a slight scurfy roughness on the discoloured parts; but this is in some cases scarcely perceptible, and there is no elevation or distinct border to the patches. It is to be remarked, that these patches do not appear, like ephelides and freckles, on the face and hands, which are exposed to the sun, but chiefly on covered parts, as was long ago remarked by Sennertus, who has given an accurate description of this eruption under the appellation of "*macula hepatica*," or *liver-spots*, probably from their colour. See his Pract. Med. lib. v. part iii. sect. i. cap. 7.

The *pityriasis versicolor* is in itself of little moment; for it is not accompanied by internal or constitutional disorder, and very rarely by any troublesome sensations, if we except a slight itching when the patient becomes warm in bed, after strong exercise, or drinking warm liquors. It is sometimes, however, supposed to be the consequence of the venereal poison, from its brown and almost coppery hue. But independently of its indisposition to terminate in ulceration, however long it may remain, its distribution and situation, and the absence of all other syphilitic symptoms, will be sufficient to enable an observer of moderate experience to distinguish it. Those who have resided in warm climates seem to be most liable to this disorder. Dr. Willan has

stated, that internal medicines have not appeared to have much influence on this eruption: but Dr. Bateman is of opinion, that the oxygenated muriatic acid is possessed of some efficacy, and that the use of pitch, in the form of pills, would probably be serviceable. Externally, however, active stimulant applications have often decidedly removed the disorder; such as lotions containing alcohol, muriatic acid, or caustic potash, properly diluted with distilled water. Sea-bathing has also been found beneficial.

There is also a *fourth* variety, the *pityriasis nigra*, which seems to have been noticed only in children born in India, and brought to this country. It is said to have commenced in a partially papulated form, terminating in a black discoloration of the skin, with slight branny exfoliations; and to have sometimes affected half a limb, as the arm or leg, or sometimes the fingers and toes. See Willan on Cutan. Diseases, part ii.; and Bateman's Pract. Synopf. of Cutan. Diseases, p. 44.

PITYRODIA, in *Botany*, $\pi\iota\tau\upsilon\rho\delta\iota\alpha$, branny. Brown Prodr. Nov. Holl. v. 1. 513.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Verbenaceae*, Juss. in Ann. du Mus. v. 7. 63. Brown.

Ess. Ch. Calyx bell-shaped, in five equal segments. Corolla funnel-shaped; its upper lip cloven half-way down; lower in three deep equal segments. Stigma cloven. Drupa dry at the summit, of four cells, perforated at the base. Seeds solitary in each cell.

1. *P. falsifolia*.—Found by Mr. Brown in the tropical part of New Holland. A scrub, with scaly or bran-like pubescence; whence the name was chosen. Leaves opposite, simple, lanceolate, nearly entire, rugose, with a strong smell, and nearly the taste of mint. Flower-stalks axillary, opposite, many-flowered, densely clustered. Flowers white. This genus is very nearly akin to *Callicarpa*. Brown.

PITYUS, in *Ancient Geography*, a town situated upon the Euxine sea, at the distance of 44 miles W. from Dioscurias, or Sebastopolis, which was considered as the utmost boundary of the Roman empire, according to Arrian. This city was provided with a convenient port, and fortified with a strong wall. The Goths, in their first naval expedition, met at this place with resistance more obstinate than they had reason to expect from the feeble garrison of a distant fortress; they were repulsed; and their disappointment seemed to diminish the terror of the Gothic name. As long as Suceffianus, an officer of superior rank and merit, defended that frontier, all their efforts were ineffectual; but as soon as he was removed by Valerian to a more honourable but less important station, they resumed the attack of Pityus; and, by the destruction of that city, obliterated the memory of their former disgrace.—Also, a river of Asia, in the Colchide.

PITYUSA, an island of the Ægean sea, in the Hermoniac gulf, S.E. of the peninsula of the Argolids, and S. of the promontory Bucephalium.

PITYUSÆ INSULÆ, islands of the Pityuses, or of Pines, so called on account of the number of these trees which grow upon these islands. Elufus or Ivica, &c. belonged to this group.

PITYUSE ISLES, in *Geography*, are islands of the Mediterranean, contradictinguishd from the *Bileavis*, and so called; according to Ptolemy, Strabo, and Pomponius Mela, from the Greek word $\pi\iota\upsilon\varsigma$, a pine, whence $\pi\iota\upsilon\sigma\sigma\alpha$, abounding in pines. These are Ivica, which is the largest, (see IVICA,) Fromentera, S. of Ivica, separated from the coast by a channel one league and a quarter in breadth, three leagues in extent from E. to W., and from two leagues to a quarter of a league in breadth, containing about 200 inhabitants, and supplying

plying wood, stone, and corn, from which last article it is said to derive its present name; the three Conejeras to the west of the former, which, though of considerable extent, are destitute of habitations, and furnish food for the flocks of the neighbouring isles; three small islands, called the gates of Ivica; the isle of Grossa; the isles of Santa Eulalia y de Arabi, lying towards the E.; the isles of Margueritas, &c. The inhabitants of these islands, the climate of which is mild and healthy, pay little attention to commerce; but as the land, which is mountainous and well wooded, is adapted to all sorts of husbandry, the occupiers cultivate olives, vines, and corn; and raise from these productions a greater quantity than they consume; but they are forbidden to export corn, oil, and fruits, and therefore, notwithstanding the richness and productiveness of their soil, they almost all live in a sort of indigence; salt and wool are the only commodities which are exported in foreign bottoms. Their habits are much the same with those of the inhabitants of the Balearic islands, one of the chief of which is indolence; their language is also much the same. They keep a number of holidays, which they devote to the purposes of religion, or superstition; and they have assemblies and some amusements. They are reckoned courageous, and display proofs of valour in their contests with the pirates on the coast of Barbary. The people are in general ignorant, and have hitherto little availed themselves of any opportunities or means of improvement.

PITZEN, a town of Prussia, in the province of Bartenland; 9 miles S.S.W. of Rastenburg.

PITZIUNTA, or DANDAR, a town of Circassia. N. lat. 43° 45'. E. long. 59° 10'.

PIVA, *Ital.*, a bagpipe. See CORNAMUSA.

PIUHEGA, in *Geography*, a town of Italy, in the department of the Mincio; 4 miles N. of Mantua.

PIVOT, or PEVOT, a foot or shoe of iron, or other metal, usually conical, or terminating in a point; whereby a body intended to turn round bears on another fixed at rest, and performs its circumvolution.

The pivot usually bears or turns round in a sole or piece of iron or brass, hollowed to receive it.

Large gates, &c. usually turn on pivots. The ancients tell us, they had theatres in Rome, that held eighty thousand people, which have yet turned on a single pivot.

PIVOT (*Fr.*), in *Military Language*, is that officer, serjeant, corporal, or soldier, upon whom the different wheelings are made in *military evolutions*; which see. Of these pivots, two sorts are distinguished according to the position of the troops that are governed by them; *viz.* *standing* and *moveable* pivots. When a battalion, *e. g.* stands in open column of companies, the "right in front," the last man upon the left of the front rank of each company, is called the *inner*, or *standing* pivot; and the first man upon the right ditto is called the *outer*, or *wheeling flank*. The accurate position of the different pivots is an object of great importance with regard to military movements, and officers, in particular, ought to recollect, that when they are posted upon the flanks, they become absolutely necessary to the preservation of that perpendicular and parallel order of a march, without which direction, the best concerted manœuvres must be ultimately rendered useless. At the instant when an officer has wheeled his division, he must resume his perpendicular position, look steadfastly on his leading pivot, maintain his relative distance, and keep his person perfectly square. He ought likewise to be particularly correct in stepping off when the wheel is completed. The *moveable* pivot is one which, during the wheel of its division, advances in a circular direction, instead of turning on the spot where it origi-

nally stood. Thus, when divisions, &c. are successively wheeled, without being first halted, the pivot upon which they wheel is said to be *moveable*. In the drill, single ranks are frequently wheeled on a moveable pivot. In which case, both flanks are moveable, and describe concentric circles round a point, which is a few paces distant from that which otherwise would be the standing flank; and all eyes are turned towards the directing pivot man, whether he is on the outward flank, or on the flank to which the wheel is made.

PIVOT-Flanks, the flanks upon which a line is formed from column. When the right of the battalion is in front, the pivot-flanks are on the left of its several companies, platoons, &c. and *vice versa*, when the left is in front.

PIVOT-Flank Officer, the officer who is on the first flank. In all wheelings during the march in column, the officer on that flank upon which the wheel is made, must consider himself as the pivot.

PIVOTS, *Platoon*, the men upon whom a battalion marches in column of platoons, is wheeled up into line, or backward into column, when the line has been formed according to a given point.

PIURA, in *Geography*, a river of Peru, which runs into the Pacific ocean, S. lat. 5° 33'.

PIURA, a town of Peru, and capital of a jurisdiction of the same name, in the bishopric of Truxillo. This was the first Spanish settlement in that country, and was founded in the year 1531, by don Francisco Pizarro, who built the first church in it. It stood first in the valley of Targafale, and was called "St. Miguel di Piura;" but it was removed, on account of the infalubrity of the air, to its present situation, on a sandy plain. The houses are constructed either of bricks baked in the sun, or of a kind of cane called quincas, and they have generally only one story. The corregidor, and an officer for collecting the royal revenue, reside here and at Payta six months alternately. The town contains about 1500 inhabitants, none of whom are persons of distinction. Although the climate is hot and dry, it is not upon the whole unhealthy. As the country is level, water is easily conveyed to different parts by canals. But in summer, when water is scarce, they are under a necessity of procuring it by digging wells in the bed of the river. This town has an hospital, under the care of the Bethlehemites, which is remarkable for the cures afforded to a great number of persons labouring under the venereal disease; 25 miles S.S.E. of Payta. S. lat. 5° 15'. W. long. 80° 40'.

PIUS I., pope, in *Biography*, a native of Aquileia, who flourished in the second century, was probably the successor of Hyginus, and in that case commenced his pontificate about the year 143. According to Eusebius, he died in the year 157. Other historians, as Cave, Pearson, and Dodwell, imagine that he presided over the see of Rome between the years 127 and 142, while Bellarmine and Baronius date his elevation to that high dignity in the year 158. In the Roman martyrology he is said to have suffered death, for the sake of his religion, under the reign of Antoninus Pius, but there seems no good authority for this fact, and the title of martyr is not given to him by Irenæus. Two "Letters" to "Justus of Vienne," which were formerly attributed to Pius, may be found in the second volume of the "Orthodoxographia," and likewise in the "Bibl. Patrum," but they have long since been given up as spurious, and allowed to be the production of a much later age. Moreri. Bower.

PIUS II., pope, whose original name was Æneas-Sylvius-Piccolomini, was descended from one of the most illustrious families of Sienna, in Tuscany, which had been expelled

pelled from that city, together with the rest of the nobility, by the popular faction, and settled at the small town of Corignano. At this place he was born in 1405, and afterwards initiated in the rudiments of grammar learning, but by the losses sustained by his father in those times of trouble and turbulence, he was unable to procure for Æneas the benefits of a college course of education, and the youth was under the necessity of assisting in the labour by which the family was supported. His talents and desire of literary improvement led some of his friends and relations, about the year 1428, to send him to the university of Sienna, where he was maintained at their expence. He quickly afforded strong proofs of an extraordinary genius. He applied himself with ardour to the study of the belles lettres, making himself acquainted with the writings of the poets and orators, and during his academical course, he published several Latin and Italian poems, which were received with applause by the learned. After this he directed his attention to the civil law. In the year 1431, his learning and accomplishments recommended him to the notice of cardinal Copronica, whom he accompanied to the council of Basil in the capacity of secretary. Here he gained the confidence of the fathers, by the zeal with which he espoused their cause against pope Eugenius, and the many learned and elegant speeches which he made, to prove the superiority of general councils over the bishops of Rome. He was immediately raised to the important offices of secretary to the council, clerk of the ceremonies, abbreviator of the letters, and one of the collators to benefices. He was also employed by the council on missions of importance to Trent, Constance, Frankfort, Swabia, Straßburg, Savoy, and the Grisons, and as a compensation for his very useful services, he was presented to the provostship of the collegiate church of St. Lawrence at Milan. He was superior to the threats and anathemas of Eugenius, and continued firm in his adherence to the fathers, while a multitude of others deserted their cause through fear. His example prevented many from defection, who were wavering as to the side they should espouse. On account of his resolution and zeal, when the council passed sentence of deposition against the pope, in the year 1439, and elected Amadeus, duke of Savoy, in his stead, Æneas was made secretary to the newly elected pontiff. Shortly after this, he was sent to promote the interest of Felix, at the court of the new emperor, Frederic III., where he was honoured by that sovereign with the title of poet-laureat, and even admitted into the number of his personal friends. In 1442 the emperor prevailed upon him to resign his other offices, and to enter wholly into his service, on which occasion he was made prothonotary, or secretary to the empire, and distinguished with the dignity of senator. From this time he appears to have had higher objects of ambition than he had before conceived, and he omitted no means of strengthening his own interest, by adopting all the sentiments of his imperial master. When, therefore, the emperor embraced a neutrality between the council of Basil and Eugenius, Æneas, notwithstanding what he had before done, followed his master's example. Afterwards, when the emperor seemed inclined to the cause of Eugenius, in opposition to that of the council and Felix, Æneas conformed himself to his sentiments, and represented his person at the diet of Ratibon, where the means of putting an end to the schism in the church were taken into consideration. At length, in 1446 and 1447, he was sent by Frederic to Rome, to negotiate the submission of Germany to Eugenius; of which opportunity he availed himself to shew contrition for his past conduct, and solicit with all humility the forgiveness and favour of his holiness. Eugenius met his

wishes, but did not live long enough to bestow upon him any substantial mark of his regard. By his successor, Nicholas V., Æneas was preferred to the vacant see of Trieste, in Istria; and upon his return to Germany he was made one of the council to whom was entrusted the management of the most important concerns of the empire. Four years afterwards he was translated to the vacant see of Sienna. In the year 1451, he accompanied Frederic to Rome, when he went thither to be crowned by the pope, and on his return, the bishop was invested with the legantine power over Bohemia, and the whole Austrian dominions. After this, in the year 1456, he was promoted by Callixtus III. to the dignity of cardinal, and upon the death of that pontiff he attained the great object of his ambition, being raised, by the unanimous suffrages of the conclave, to the popedom, and at his coronation, he assumed the name of Pius II. Much was expected from him on account of his great learning, and the zeal which he had formerly shewn in setting forth the corruptions that had been introduced into the church. He, however, soon convinced his friends, and the friends to a better order of things, what they had to hope for now he was elevated to the highest station in the world. His ambition was gratified, and what formerly had been deemed corrupt principles and practice, he found means to justify, or at least overlook. One of the first measures of his government was an attempt to unite the Christian princes against the Turks: for this purpose he appointed a council to meet at Mantua in 1459, at which he invited all those princes to attend, either in person or by their ambassadors, for the purpose of deliberating on the most effectual methods of delivering Christendom from the bondage with which it was threatened by those formidable enemies. At this council Pius himself presided, and the attendance of princes or their representatives was very numerous; but their various and opposing interests rendered all the endeavours of the pope to unite them quite ineffectual, and the council broke up without concurring in any resolution to oppose the progress of the common enemy. He next declared the kingdom of Naples devolved as a fief of the church to the apostolic see, and confirmed the bull of king Ferdinand's legitimation, upon his restoring to the church some places that had been captured by his father. He also granted Ferdinand the investiture, and sent a cardinal to perform the ceremony of his coronation. The king, on his part, engaged to assist the pope against his enemies with the whole strength of his kingdom. To secure the throne of Naples to Ferdinand, Pius ordered all the clergy and barons, under pain of excommunication, to acknowledge him, and no other, for their lawful sovereign, and sent a body of troops to his assistance when John of Anjou invaded the kingdom. In 1460 he gave a most decided proof of his bad faith, by publishing a bull, condemning the doctrine, which he had formerly defended, of the superiority of a general council to the pope, and forbidding all appeals to such a council under the severest penalties. He also attempted to obtain from Charles VII. king of France, the revocation of the *PRAGMATIC Sanction*, (see that article,) which he pronounced to be an edict highly derogatory to the honour and dignity of the holy see. This edict had been drawn up by Charles, or at least by the prelates of his kingdom, and it was thought necessary, in order to deliver the French clergy from the vexations which they suffered from the encroachments of the popes, ever since the latter had fixed their residence at Avignon. It had been drawn up in concert with the fathers of the council at Basil, and the articles of which it consisted were taken from the decrees of that council. In answer to Pius's request, the French king

replied, that the edict consisted of the very decrees of the council of Basil, which Pius himself had approved, had penned, and probably had suggested, when secretary to that assembly, and which it had received with one consent, and observed for the space of twenty-five years by the whole French nation. Upon the death of Charles, the pontiff renewed his application to his successor Lewis XI., who consented to abolish the edict by a solemn declaration, for which he and his successors were rewarded by the title of "Most Christian," a title which descended uninterruptedly to Lewis XVI., and was only abolished with the destruction of the monarchy. Though the king thus degraded himself by becoming a tool to the pope's ambition, his council better consulted the dignity of their sovereign, and their own reputation, by resisting, to a man, the pope's demand; and the full execution of Lewis's declaration was prevented by the noble stand made by the university of Paris, and the parliament, in favour of the "Pragmatic Sanction."

During the years 1462-3, Pius again, but unsuccessfully employed all his talents and eloquence in endeavouring to unite the Christian princes against the Turks, who had at that time made themselves masters of almost all Greece. Finding his efforts of no avail, he equipped a fleet at Ancona, avowing his determination, notwithstanding his age and bodily infirmities, to face the inconveniences and dangers of war, imagining, that with such an example, the Christian princes would be ashamed of remaining quiet and inactive at home. While, however, he was thus busily employed, he fell sick, and was advised by his physicians to pay a visit to Sienna, for the benefit of his native air. Before he left Rome, he published a solemn retraction of all that he had written in favour of the council of Basil, and declared, without shame or hesitation, that, as Æneas Sylvius he was a damnable heretic, but as Pius II. he was an orthodox pontiff. After a very short stay at Sienna he returned to Rome, but being informed of the inroads of the Turks, and that they had actually laid siege to Ragusa in Dalmatia, he set out without delay for Ancona, though at that time he was in so infirm a state of health, as to be obliged to travel in a litter. The journey, however, proved too much for him, and he died in the summer of 1464, at the age of fifty-nine, having filled the pontifical throne six years within a few days. According to Platina, he was endowed with every virtue that became his exalted state; but the conduct of the pope certainly militated against the excellent qualities which he had displayed, previously to his advancement to that high dignity. No man ever laboured harder, and perhaps few more successfully than Æneas Sylvius, to restrain the power of the pope within the boundaries admitted by the canons, and no pope ever strove more than Pius II. to extend that power beyond all the bounds of reason and law. To effect his purposes, he spared neither kings, dukes, nor people, when he assumed that they invaded the rights of the church, or entrenched upon the emoluments of the clergy. When young he indulged his passion for the sex without restraint, and in his more mature years, he seems to have thought transgressions against the rules of chastity to be very venial sins, if they could even be denominated sins. As a scholar, he was an elegant writer in Latin, and left behind him various works, most of which he composed before his elevation to the papedom. Of these an abridged list is given in the General Biography, but a complete catalogue of them may be found in Cave and Dupin. The following seem to be the most generally important: "Comment. de Gestis Concilii Basiliensis;" "De Ortu, Regione, ac Gestis Bohemorum ad Ann. 1458;" "Cosmographicæ, seu Historiarum de Mundo universo;"

"Epistolæ Liber," containing four hundred and thirty-two letters, many of which are interesting and curious. The whole works of this pope were published in a collective form at Basil in 1551, and again at Helmstadt in 1700. A history of his life was published at Rome in 1584, which was generally believed to have been drawn up by himself. Moreri. Mosheim.

PIUS III., pope, whose original name was Francis Todeschini, was a native of Sienna, and born in the year 1429. He was nephew on the maternal side to Pius II., and was permitted to take the name of Piccolomini, and to bear the arms of that family. When he was but twenty-two years of age, Pius raised him to the dignity of cardinal, and nominated him to the bishopric of Sienna. He was employed in several legations by popes Paul II., Innocent VIII., and Alexander VI., to whom he gave the most entire satisfaction, by the prudence and integrity with which he discharged the several commissions and high trusts reposed in him. Upon the death of Alexander VI. in 1503, the city of Rome was thrown into the utmost confusion by the struggles for power between Valentine Borgia, the son of Alexander, and the Orsini, and others whom he had deprived of their estates. Scarcely a day passed in which there were not battles fought in the streets by the partisans of these rivals. The cardinals, therefore, found it quite necessary to raise a considerable body of troops for their own defence, while they should be shut up in conclave. They also applied to the ambassadors then residing in Rome, by whose means the heads of the opposite factions were prevailed upon to withdraw from the city, till the election of the new pope should be declared. The choice soon fell upon Piccolomini, who, out of grateful respect to the memory of his uncle, assumed the name of Pius III. As soon as the intelligence of his election had reached the hostile factions, they returned to Rome, and renewed the war within the walls, throwing the city into the utmost confusion. Valentine was soon obliged to submit to the enemy, and he was then left to the mercy of the pope, who permitted him to retire unmolested wherever he pleased. Pius, by this event, had the happiness to see peace restored to the city, but he did not live long to enjoy it, as he died on the 26th day after his election, being in the 75th year of his age. It was generally believed, that he was taken off by poison. He was regarded as a person of unblemished moral conduct, and in every respect worthy of the high dignity to which he had been raised. Bower. Moreri.

PIUS IV., pope, whose original name was John Angelo di Medici, was born at Milan in the year 1499. He wished to be thought a branch of the famous house of Medici, to which he had no real pretensions, being, in fact, of low origin, and whose real name was Medicino instead of Medici. He enjoyed the advantages of a liberal education; and having applied himself chiefly to the study of the civil law, he was in early life admitted to the degree of doctor. After this he practised with high reputation as a civilian, and by his abilities, united with the interest of a brother, he obtained the office of prothonotary under Clement VII. In this situation he recommended himself to the favour and patronage of cardinal Farnese, who, after his elevation to the papal dignity under the title of Paul III., employed him in various legations. By the same pope he was appointed commissary to the army of the church; nominated archbishop of Ragusa; and created cardinal priest of Santa Prisca in the year 1549. Upon the death of pope Paul IV., in 1559, the conclave was agitated for more than four months by the intrigues of different cardinals of noble families, whose power was so equally balanced, that neither of them

them could obtain the requisite superiority over his rivals; till at length, wearied out with their fruitless struggles, they gave their united votes in favour of the cardinal of Santa Prisca; who, at his consecration, took the name of Pius IV. He began his pontificate with granting a general pardon to all who had been concerned in the outrages committed since the death of his predecessor, and he then took measures for bringing to justice the persons whose oppressive enormities had provoked them to their irregular conduct. The Caraffas were accordingly arrested, tried, and convicted of crimes, for which they were condemned to forfeit their lives and their estates. The cardinal was, in pursuance of the sentence, strangled; and his two brothers, the duke of Pagliano and marquis of Montebello, were beheaded, with several of their accomplices. One of the early measures of this pope's administration was to terminate the differences between the papal and imperial courts, occasioned by the late pope's refusal to approve Ferdinand's succession to the imperial crown, resigned to him by his brother Charles V., without applying in the first instance for the consent of his holiness. He next adopted certain measures, with a view, if possible, of putting a stop to the progress of the reformation. The power and influence of the Protestants were now every day becoming more and more considerable. England and Scotland had disclaimed allegiance to the see of Rome, and had new-modelled their religion. In the Netherlands, the reformers had greatly multiplied; and in France, there was reason to apprehend that they soon might become too powerful for the Catholics. The new opinions had penetrated even to Italy. From Naples they were extirpated by Philip II., who issued orders to his viceroy to put all heretics to death without mercy. But the duke of Savoy was inclined to attempt to enlighten and convert them; and, with this view, he desired the pope's permission to hold a conference of the principal ecclesiastics in his dominions, on the subject of religion. France determined to have recourse to the same expedient. The pope promised that he would summon a general council without delay, which he did, to meet at Trent. The bull was drawn up in such equivocal expressions, as might be interpreted to signify either a new council, or a continuation of the former one at the same place. The emperor, the French king, Philip, and the other Catholic princes, received the bull, and gave orders to the ecclesiastics in their dominions to repair to Trent, at the time appointed. An invitation to attend was also sent to the several Protestant powers; but they all resolved to give no encouragement to a council, which was called by one whose authority they could not acknowledge, and in which only those were to have decisive votes, who had sworn allegiance to the pope and the see of Rome. The council opened in January, 1562. Attempts were soon made to abridge the authority of the pope, which created in his holiness perpetual anxiety, and he was on the point of suddenly dissolving the assembly; but he found it more expedient to flatter and cajole, than to have recourse to violent measures. In 1563 it was brought to an end, but not until decrees were passed, designed as an acknowledgment of the subordination of the council to the holy see. When information of the dissolution of the council was brought to Pius, he received it with great joy, and ordained a solemn thanksgiving on the occasion; and in a very short time, he published a bull of confirmation, requiring all the prelates and princes to receive and enforce the decrees of the council of Trent, prohibiting persons from writing any explication or commentary of them, and commanding the Catholics every where to have recourse in all doubtful cases to the apostolic see. By the republic of

Venice, the several Italian princes, most of the Catholics in Germany, and the king of Spain, the authority of the council was acknowledged, and the decrees received; in some countries, without any limitation whatever; but in Spain, and all through the Spanish dominions, with the clause, "Saving the rights of the crown, and the privileges of the subjects." Pius had the mortification to find that they met with a different treatment in France. The court refused to receive and publish the decrees, as derogatory to the liberties of the Gallican church, and the rights of the crown. In the year 1564 the pope, at the pressing instance of the emperor Maximilian II., granted the use of the cup to the laity of Austria and Bohemia; but he could not be persuaded to consent to the marriage of the priests, though earnestly intreated by the emperor, and the other Catholic princes of Germany, who declared that they could no longer bear with the impure celibacy of the clergy. This pope died in 1565, in the 67th year of his age, and after a pontificate of nearly six years. That event is said to have been accelerated by his apprehensions for the loss of Malta, which was then besieged by the Turks. The news of the fact was received with great joy by the Roman people, who hated the pontiff, on account of the severity and oppression of his government. This hatred, united with religious enthusiasm, had given rise to a conspiracy against him not long before his death; but it was discovered, and the parties concerned in it were executed with much torture. Pius is praised for the vast sums which he laid out on public works, for the convenience and ornament of Rome. According to Onuphrius, he was possessed, or at least seemed to be possessed, while cardinal, of every virtue that could render him worthy of the high station to which he had been raised; but no sooner had he attained the summit of his ambition, than he abandoned himself, without restraint, to all the opposite vices; stopping at no means of accumulating wealth, that he might enrich and aggrandise his nephews and other relations.

PIUS V., pope, whose original name was Michael Ghislieri, was descended from an obscure family, and born at Boschi, a small town near Alexandria, in the north of Italy, in the year 1504. When he was fourteen years of age, he embraced the monastic life in a Dominican convent, where he was soon distinguished by the strictness of his conformity to the rules of the order, and acquired a high character for piety and virtue. He was ordained priest at Genoa, and became a very celebrated preacher, being master of a most powerful and persuasive eloquence. Afterwards he was elected prior of the convent of Vigevani, and nominated inquisitor by cardinal Caraffa, commissary-general of the holy office, who had conceived a strong attachment to him. In a short time after, that cardinal was elevated to the papal throne, under the name of Paul IV. He made Ghislieri bishop of Sutri; and when, in the year 1557, our prelate was preparing to resign his dignity, and to return to the monastery, he was prevented by the interposition of his holiness, who promoted him to the purple, by the title of cardinal *de sancta Sabina*, though he was most commonly known by the name of cardinal Alexandrini, from his native country. He was, at the same time, appointed to the post of commissary-general to the inquisition. This office he executed with so much severity in the Milanese and Lombardy, that he was obliged to quit those countries; and his zeal was afterwards checked by the government, when he attempted to discharge the functions of inquisitor at Venice. Pius IV. translated him from Sutri to the see of Mondovi; and upon the death of that pontiff in 1566, by the unanimous suffrages of the conclave, he was elected his successor, when he

he assumed the name of Pius V. The people expressed no joy at his coronation: they dreaded a severe government under a man, in whose rigid and austere manners his successive promotions from the condition of a simple monk had made no change. Sensible of the coldness of the reception he met with, he observed to those about him, "I hope that, some time hence, the Romans will be as sorry for my death, as they are now grieved at my advancement." To render his name worthy of the grateful remembrance of virtuous and good men, he displayed great zeal and diligence in promoting a reformation in the manners and morals of all ranks of the people. He repressed the excessive pride and ostentation of the cardinals, as well as the luxury in dress and mode of living of the other orders of the clergy. He gave directions for banishing all the prostitutes from Rome, and he prohibited the bull-fights in the circus, as well as all other diversions which had a tendency to promote irregularity and dissipation among the lower classes. He gave directions for strictly enjoining on the clergy residence, and commanded that no persons should be admitted to ecclesiastical benefices, who would not reside; and when he was told, that a strict adherence to such a decree would cause the court of Rome to be deserted, he replied, that it was better that the court should be deserted, than that the service of the altar should be neglected. He ordered his own relations to retire from Rome, providing them all with small pensions for their subsistence, excepting two nephews, who were attached to study; one of whom, Michael Bonello, who possessed shining talents and an excellent disposition, he was persuaded by his friends to raise to the dignity of cardinal. While Pius V. was engaged in introducing a partial reformation among the ecclesiastics and community of Rome, he displayed a furious zeal against the Protestants, by persecuting them with the same savage severity, which rendered him odious in his former character of inquisitor. Peter Carnesecci, a person of distinction at Florence, was, by his express order, condemned to the flames, after having been convicted of corresponding with some of the reformed religion in Germany, and with some of his countrymen in Italy, who were suspected of heresy. Aonius Palcarius (see his article), one of the ornaments of his age as an elegant and liberal scholar, underwent the same fate, for saying that in some things the Lutherans were excusable, particularly for calling the inquisition "the dagger drawn against literature in general." Not satisfied with his endeavours to extirpate the reformed opinions out of Italy, he, in 1568, encouraged Charles IX., king of France, to make war upon his Protestant subjects; sending a considerable body of troops to join the royal army, and permitting some of the estates of the church in France to be alienated, in order to supply funds for carrying on hostilities. Pius V. was not outdone by any of his predecessors in zeal for maintaining the high claims of the papal see. In 1568 he published his famous bull, entitled "In Cœna Domini," which it was usual to publish at Rome on Maundy Thursday every year, till it was suppressed by pope Clement XIV. By this bull, anathemas were pronounced against such persons as should appeal to general councils from the decrees of the popes, and against those princes who should impose restraints on ecclesiastical jurisdictions, or exact contributions from the clergy. This bull, evidently calculated to deprive princes of their sovereignty, and to render them and their subjects entirely dependent on the will of the Roman pontiffs, was never received in any kingdom out of Italy. Some French bishops did, a few years afterwards, attempt to introduce it into their dioceses; but their offence against the liberties of the Gallican church was most severely punished. In

1569 Pius conferred the title of grand duke of Tuscany upon Cosmo de Medici, duke of Florence, who went to Rome, where he received the crown at the hand of his holiness; and during the same year, the pope issued a bull of excommunication against Elizabeth, queen of England, absolving her subjects from their allegiance. This paper was fixed up in the night on the bishop of London's palace, and in other parts of the metropolis; but it was very harmless, for none but a few bigotted Catholics noticed it with the smallest regard: they indeed endeavoured to excite some commotions, but their efforts were fruitless, and for the feeble attempt they paid the forfeit of their lives.

In the year 1571, the zeal of this pontiff was directed against Selim the Turkish sultan, who, in violation of a solemn treaty, had invaded the island of Cyprus. The Venetians, to whom the island belonged, solicited his holiness to employ his influence in procuring assistance for them from the Christian princes. With their request Pius readily complied. He was, however, successful in his application only with Philip II., who, without hesitation, entered into a league with his holiness and the republic, by which he bound himself to pay one-half of the expence of a powerful armament which it was judged necessary to employ, while the Venetians engaged to defray three-fourths of the other half, and the pope the remainder. The preparations of the combined powers were carried on with so much celerity and dispatch, that about the middle of September a fleet was ready to sail from Messina, consisting of more than 250 ships of war, and other vessels, carrying nearly 50,000 men. The command of this mighty armament was given to don John of Austria, whom the pope, indulging the most sanguine hopes with regard to the issue of the war, exhorted to embrace the first opportunity of engaging with the enemy, assuring him that he would obtain a complete victory. He sent him, at the same time, a consecrated standard, and a number of ecclesiastics to officiate in sacred things on board the ships; and, moreover, he ordered a fast and jubilee to be proclaimed, with an absolution from their sins to all who should acquit themselves with honour against the infidels. A victory was soon afterwards obtained by this fleet over the Turks near the gulf of Lepanto, the intelligence of which spread universal joy throughout all Christian Europe. When the important news was brought to the pope, he cried out, in the words of sacred writ, "There was a man sent from God, whose name was John," in reference to the prince under whose command the victory was obtained. (See *JOHN of Austria*.) Pius survived this event only a few months, and was carried off by an attack of the stone in 1572, when he was about the age of sixty-eight, after a pontificate of little more than six years. Notwithstanding his defects, compared with many of his predecessors, his name appears with honourable distinction among the list of popes. He was a lover and patron of learned men, and scarcely preferred any persons to considerable dignities who were not strongly recommended by their abilities, and the endowments of their minds. In his private conduct he was irreproachable and exemplary. He was beatified by Clement VIII., and canonized in 1712 by Clement XI. A volume of his letters was published at Antwerp in 1640, under the title of "*Apostolicarum Pii Quinti Pontificis maximi Epistolarum, lib. v.*" Moreri. Bower.

PIUS VI. pope, originally known by the name of John Anthony Braschi, was descended from a noble, but reduced family, and born at Cesena, a small town belonging to the ecclesiastical state, in the year 1717. Being destined for the church, and possessing a promising capacity, he received the best education that could be procured. His
splendid

splendid talents recommended him to the patronage of cardinal Ruffo, who appointed him to the post of uditore; a charge which, in the establishment of the Roman church, comprised the offices of vicar, counsellor, and assistant. In this situation he conducted himself with so much good sense, probity, and zeal, that he secured the affection of the cardinal, and acquired the reputation of being one of the best informed persons in Rome. As a mark of his esteem for Braschi, this generous prelate, when on his death-bed, left him the continuation of his appointment for life, and such was Braschi's veneration for his patron, that, out of respect for his memory, he retained the situation of uditore, even after he became pope. He continued to make rapid advances in the church, and under the pontificate of Clement XIV., more generally known by his family name of Ganganelli, Braschi was raised to the purple; and in this progressive advancement, he constantly displayed a love of justice, the strictest morality, close application to business, and the most unassuming manners. After the death of Clement XIV., cardinal Braschi was raised to the pontifical throne, and he was proclaimed pope under the title of Pius VI. He began his government with correcting various abuses which had taken place in the internal administration of affairs, as well as in the police of Rome, and with endeavours to restore the dilapidated finances to order and regularity. With this view he liberally patronized several useful reforms, and beneficial establishments in the state. Soon after his accession he had a difference with the court of Naples, which led him to display great firmness in support of his dignity. The king of the two Sicilies had appointed M. Filangeri, formerly viceroy of Sicily, to the archbishopric of Naples; and as the laws of that metropolis required that the archbishop should be a cardinal, application was made to Pius VI. to bestow upon him that dignity. The pope returned for answer, that although the laws enacted that a cardinal should be the archbishop, it did not follow that the archbishop should become a cardinal; and that his majesty, who could not be insensible of the difference, might have promoted to the archbishopric some one or other of the Neapolitan cardinals residing at Rome, instead of thus indirectly assuming authority to confer one of the greatest dignities of a foreign hierarchy on one of his subjects. The pope was resolute, and Filangeri actually died of a broken heart, in consequence of the refusal. Pius VI. derived real and very great honour from the works of magnificence and utility, on which he expended the revenues of his see. He augmented and completed the noble Clementine Museum in the Vatican, founded by his predecessor, as a receptacle for the monuments, vases, statues, medals, and other remains of antiquity, which were procured by excavations in the estates of the church. The engravings and descriptions of the treasures in this collection were afterwards published in six volumes folio. He projected and finished the erection of the present majestic vestry of St. Peter's. He built a church and established a library in the abbey of Subiaco; he founded a number of hospitals for the relief of the sick and indigent; and he shewed a great regard for the interests of commerce by repairing the port of Ancona, and erecting the beautiful light-house, which is at once an ornament to the city, and of the highest utility in the navigation of the Adriatic sea.

But the greatest economical undertaking of this pontiff's administration, was the draining of the Pontine marshes; and if he did not completely succeed, yet he is not entitled to less praise for the grandeur and utility of the attempt. The marshes extended upwards of forty miles in every di-

rection, occupying the whole valley from the Apennines to the sea. To fit this vast space for the purposes of agriculture, and by so doing to purify the air from pestilential vapours arising from it, had been an object that employed the thoughts and the labours of the censor Appius Claudius, who carried through it the famous Appian way. Several of the Roman emperors, and several of the popes had directed, at different times, their attention to the same design, and though all their attempts had been unsuccessful, Pius VI. resolved to undertake the arduous work. He employed the best engineers in Rome, and went regularly every year to inspect, in person, the progress which they had made. He caused immense canals to be dug, for the purpose of receiving the water from the marshes, and by this means rendered considerable tracts of land fit for husbandry. On the side of these canals he constructed a large and beautiful road, about forty miles in length, ornamented with four rows of poplar trees, and interspersed with houses of accommodation; and at its termination he built a large and splendid palace. Pius likewise displayed his magnificence in the reception which he gave to several royal personages from various parts of Europe, who came to visit Rome during his pontificate, among whom were Joseph II. emperor of Germany; Paul, then grand duke, afterwards emperor of Russia; Gustavus Adolphus, king of Sweden; and his royal highness of England, prince Augustus Frederick, the present duke of Susssex, illustrious as well for his attachment to the principles of civil and religious liberty, as for his high birth.

Pius VI. spent the first six years of his pontificate in the most perfect tranquillity, excepting the difference, which has been referred to, with the court of Naples, occupied in regulating the internal government of his state, and in carrying on the undertakings already noticed. Soon after the death of the empress queen, Maria Theresa, towards the end of the year 1780, he began to feel mortifications and afflictions in abundance. As soon as Joseph II. came into possession of his hereditary territories, he began to carry into execution the schemes which he had long formed for promoting a reform in ecclesiastical affairs, and emancipating his subjects from papal jurisdiction. With this view he issued edicts and ordinances, by which the secular clergy were subjected to lay-magistrates: all donations to religious houses, by those who should enter them, were prohibited; various religious houses, in all parts of his dominions, were suppressed; all Austrian, Hungarian, and Lombard bishops were enjoined never to accept the dignity of cardinal; all subordination to the holy see in secular affairs was disclaimed, and many other vigorous steps towards a complete emancipation were pursued. These proceedings excited the greatest alarm in the breast of Pius VI. At first he hoped that some opposition would be made to such innovations by the imperial subjects themselves; and he was encouraged in that hope by the strong remonstrances which were sent to the emperor, from the clergy of Brabant, Flanders, and Lombardy. They, however, produced no effect on Joseph, who persisted in his schemes, supported by the assistance of the lay magistrates and the military power. Even the archduke Ferdinand, his brother, had been nearly deprived by him of the government of Lombardy, for seconding the remonstrances of the Milanese clergy. Under these circumstances, his holiness thought it high time to remonstrate himself against the imperial measures, and directed his nuncio at the court of Vienna to present the most pressing solicitations to his majesty, that he would consider the consequences of his proceedings. But these produced no effect whatever, and the prince Kaunitz told him, that

that his master was fully aware of the effects of what he had done, and was determined to carry into execution all the edicts that he had issued.

The thunders of the Vatican were no longer objects of terror, and of this Pius VI. was fully aware; he therefore resolved to try whether his personal entreaties might not have the effect of prevailing with the emperor to desist from his hostile purposes. He accordingly determined to visit that prince at Vienna. This determination was highly disapproved by the members of the sacred college; Pius was, however, resolute, saying that he had rather submit to humiliation in his dignity than remorse in his conscience. At that time, inauspicious as his prospects were, he little thought of the afflictions that were in reserve for him in another quarter, and from another power than on the best terms with the papal see.

The pope, after the fatigues of a winter's journey over the Alps, arrived at Vienna in March 1782, where he was received by the emperor with every mark of external respect, and who treated him with the same distinction as if he were in possession of that vast power which his predecessors had enjoyed, and was reigning in his own capital. The emperor and pope had repeated conferences on the subject of the changes which Joseph was making in ecclesiastical matters; but the arguments of Pius were not sufficiently strong to induce the emperor to repeal any of his late edicts, and he could only obtain a respite for some religious foundations which were threatened with dissolution. While Pius continued at the Austrian capital, he is said to have received several Protestant princes, noblemen, and clergy, with the greatest affability; and it has been likewise asserted, but upon no proper evidence, that he converted to the Catholic religion many thousand Protestants, who had come to Vienna for the purpose of seeing him perform the duties of his high office on Easter Sunday. After the pope's return from his visit to Vienna, he employed much of his time in the improvement of his temporal dominions, and in the enriching and aggrandizement of his own relations. One nephew he made a cardinal, and another he raised to the dignity of a ducal coronet, circumstances that created much disaffection to his government from the people, who saw them grow wealthy by the plunder of the estates belonging to the apostolical chamber, and the most oppressive public spoliations. In the mean time he was involved in new disputes with the court of Naples, which, encouraged by the example of the emperor, had abolished some of the prerogatives that the court of Rome had for ages been accustomed to exercise in the Neapolitan dominions, as well as the singular custom of delivering a white horse to his holiness on St. Peter's day, as a token of feudal vassalage to the holy see. In 1787 the matter was carried much farther, and the king of Naples absolutely prohibited any appeal from his decisions to the court of Rome, and at one blow abolished for ever certain feudal homages which he conceived as disgraceful to his own dignity any longer to submit to. When the pope heard of these proceedings, he issued a solemn protest against the innovations made by them on the sovereignty of the holy see over the kingdom of Naples. He sent his internuncio to Naples with certain apostolical bulls; but the decrees produced no effect, and the messenger of them was banished the kingdom of Naples. This was in the autumn of the year 1788, at a time when Pius had a misunderstanding with the grand duke of Tuscany, respecting some innovations of the bishop of Pittoia; this at length changed into a violent quarrel, in which the grand duke undertook to annihilate the spiritual power of the pope in his dominions, and to counteract his supremacy in the

hierarchy of the state. The effects of a similar spirit were manifested by the Venetian republic, the senate of which had, in the early part of this pope's reign, secularized a number of abbeys, and other rich establishments, and incorporated them with those belonging to the nobility. On account of these proceedings, the pope had threatened them with the effects of his apostolical anger, and even gone so far as to talk seriously of compelling them to obedience, by the force of temporal arms. This quarrel had at one time been appeased, by the intervention of certain cardinals, but the senate continued in its laudable labours of suppressing and reforming conventual houses in favour of hospitals and other charitable establishments, without paying any regard to the murmurs and complaints of the pontiff. The duke of Modena, likewise, without the concurrence of the holy see, suppressed the inquisition in his state, and was preparing, if it should appear necessary, to arm against the pope in defence of certain territorial rights. After all, these were the commencement of evils, and of no sort of consequence, compared with what Pius VI. was on the point of enduring from revolutionary France. In that country, before the assembling of the states-general, a disposition was shewn by many of the higher clergy to introduce reforms in matters of an ecclesiastical nature, without any application for the concurrence of the holy see. The French government, likewise, without communication with the court of Rome, had suppressed the order of the Celestines in France, and seized upon the estates of those of the same order, who, living under the Roman jurisdiction at Avignon, had property in the French territory. These circumstances filled the heart of Pius VI. with an overwhelming anxiety, which was augmented by the edict that was passed in favour of the Protestants, granting them a civil existence, and legitimating their children. Pius was urged by some of the members of the sacred college to adopt violent measures in defence of his dignity and just right; but he preferred moderate measures, and was contented to mourn in silence over these daring attacks upon his office, and that toleration of heretics which threatened ultimate ruin to the Catholic church.

In the following sketch we shall be as brief as possible, and endeavour to omit every circumstance that is not connected with the subject of the present article. The downfall, however, of the papal authority is of too great importance to the world to be lightly passed over: that power that tyrannised over the consciences and temporal rights of mankind for many centuries, so that to have lived to behold its humiliation and almost entire destruction, is no small privilege of the existing generation.

After the states-general in France had assembled in 1789, one of the first abuses which was the object of public attention, and which, it is believed, the court even had previously resolved to sacrifice, was the payment of ecclesiastical tribute to Rome, under the form of bulls, dispensations, and other objects of spiritual traffic. This was followed by a decree of the National Assembly, at the close of the year, declaring the church estates to be national property, which filled the court of Rome with general consternation. At length the pope's temporal possessions in Venaissin and Avignon were confiscated by the National Assembly. Against this seizure of his property, briefs and bulls were issued by the pope; and the partizans for his holiness, and the friends to the French revolution in the country which was the object of dispute, carried on against each other what was called a *civil*, but a bloody contest. At length the revolutionists of Avignon gained the ascendancy; and after dethroning the archbishop, and dispersing the clergy for refusing to take

take the civic oath, they deposed the pope from his sovereignty, seized his revenues, and Avignon, with the whole of the papal territory in France, was converted into republican departments. When the National Assembly had formed their civil constitution for the clergy, the pope was solicited by the anti-constitutionalists, with the abbé Maury at their head, to suppress it by an apostolical bull. Accordingly he dispatched, with this view, his celebrated monitory of the 13th of April, 1791. But this instrument, so formidable in former times, now served no other purpose than to excite ridicule, increase the severity of the proceedings against the non-conforming clergy, and to excite popular odium against his holiness. In Paris it was regarded as the tocsin for a civil war, and the mob, without hesitation, to express their resentment against the power which issued it, burnt the effigy of the pope, in all his pontifical insignia, in the garden of the Palais Royal.

The hostility of the court of Rome to what was transacting in France was not confined to briefs and bulls, but was displayed in prosecutions against such persons as were suspected of any attachment to the revolution which had taken place. Several officers, natives of France, but in the pope's employ, were degraded, and sent to the galleys, for having discovered sentiments favourable to the new order of things. A kind of proscription, likewise, was begun against every thing or person which bore the name of French or Frenchman, till it was suspended in consequence of the interference of the executive council of the French republic, which threatened hostilities, if redress were not instantly obtained. After the appearance of the *famous* manifesto issued by the duke of Brunswick of the coalition of crowned heads, against the French republic, menacing with extermination all who should dare to resist the forces employed in maintaining the cause of royalty, military preparations were begun to be made in the papal dominions, which could not but be considered by the French government as intended to strengthen the power of their enemies. This suspicion was confirmed by the circumstances connected with, and immediately following the murder of Bassville, the French ambassador, by the mob of Rome. That minister had been sent, in 1793, to dissuade the pope from joining the league against the republic, and had been instructed to erase the royal arms from the French academy, and all public buildings belonging to the nation, and to substitute the republican insignia in their place. Pius, however, refused to acknowledge him as the representative of France, till a reparation had been made to the holy see for its wrongs. Bassville being prevented from displaying on the public buildings the emblems of his own government, determined to maintain its honour in his own personal appearance, and without hesitation openly paraded the streets with the national cockade in his hat. He had not worn it many days before he was assassinated in the streets. This deed was condemned in very gentle terms by the pope, who probably was not grieved at what had happened; instead, therefore, of making concessions, and endeavouring to discover and punish the perpetrators of the act, he openly declared against the French republic. His manifesto, which ordered a general armament, avowed the intention of assisting to exterminate the sworn enemies of all thrones and altars. The manifesto offered also amnesty and absolution to criminals who should take up arms for the church and state, and exempted no persons from the rising in arms but children, old men, and priests, "who were to raise up their hands on the mountain, while the faithful fought in the plain." The pope, for want of money, was unable to keep his army together, and in a very short time he was glad to change his tone, and to de-

clare himself neutral; he had not, however, wisdom and prudence sufficient to be steady in his neutrality. In 1796, when Bonaparte was every where victorious, Pius committed an act of aggression by suffering the Neapolitan cavalry who were hastening to their succour to pass through the territories of the church, and even directed their march. No sooner had the conqueror dispersed the Austrian armies in Italy, than he proceeded against those Italian states which had either joined or favoured them. Having with his main army entered the territory of the pope, and without resistance taken possession of Bologna, Ferrara, and Urbino, the pontiff was under the necessity of throwing himself on the clemency of the conqueror, who would not even grant him an armistice but on very severe conditions. By the terms of it, the pope was compelled to set at liberty those persons who were at that time confined for their political conduct or opinions, to renounce the friendship of the coalsted powers, and to shut up his ports against them; to surrender to the French the cities of which they already had possession, as well as the citadel of Ancona, to pay nearly a million sterling, and to deliver one hundred pictures, busts, vases, statues, &c. and five hundred manuscripts, to be selected by commissioners who should be sent to Rome for that purpose. When the terms of peace came to be discussed, the pope refused to accede to those conditions to which he had agreed when the armistice was concluded.

The court of Rome had now the temerity to resolve trying the fortune of its arms against those of France, having been promised the assistance of a considerable body of troops by the court of Vienna. Every effort was now made by the pope, but he was ill-seconded by his subjects, many of whom were more anxious to welcome the French to Rome than prevent their arrival. The crisis soon arrived which brought affairs to an issue, and exposed the fatal policy which had directed the determination of the papal cabinet. A series of ill success obliged his holiness to conform all the conditions of the armistice without reserve; to admit the annexation of Avignon and Venaissin to the French republic; and he likewise consented to pay thirty millions of livres, as well as to furnish the French army with 16,000 horses, by way of ransom for the remnant of his dominions which he was permitted to retain. By this peace the political existence of the holy see was prolonged for a short time, but it was left in a state of extreme embarrassment: and the pope, who had already demanded of his subjects the half of their plate, was now obliged to call upon them for the remainder, requesting that it might be brought into the pontifical treasury within three days. This requisition produced much discontent and murmuring among the people, and strong symptoms of a revolutionary spirit were discoverable in all parts of the ecclesiastical state. The popular odium was particularly manifested against the duke of Braschi, on whom was lavished every expression of indignation and contempt. To check and restrain these tokens of public hatred and disaffection, the government of the court of Rome became severe and tyrannical. To overawe the people a strong garrison was placed in the castle of Angelo, and soldiers were distributed in different quarters of the city. These severities directed the public resentment against the pope, who could never appear abroad without receiving the strongest marks of disapprobation. Political conspiracies were every day forming, and in this distracted situation of affairs Joseph Bonaparte, the brother of the general, arrived at Rome in the quality of ambassador from the French republic. This was highly acceptable to those who were planning a change in the government, and towards the end of December 1797, an insurrection broke out, attended with very

disastrous circumstances, in consequence of which the French ambassador quitted Rome, and retired to Florence. In the commotion the French general Duphot had been most inhumanly murdered, of which the directory at Paris made a handle for seizing the remaining treasures of the ancient metropolis of the world, and for assuming the glory, if such it could be denominated, of erecting the Gallic standard on the Capitol. Orders were instantly given for the march of the French and Cisalpine forces to Rome. To deprecate, if possible, the wrath of the French government, and ward off the fatal blow, solicitations were made for the mediation of the Spanish ambassador, and that of the courts of Naples; Florence, and Vienna. The intervention of heaven was also sought by prayers, fastings, processions, and jubilees. The theatres were shut up; and new and numerous arrests of suspected persons were ordered to be made. In contempt of these acts of government, the revolutionary party covered the walls with satirical and menacing placards; and they also distributed among the people portraits of Bonaparte, with the title of the new saviour of the world. In the mean time the French and Cisalpine armies, under the command of general Berthier, marched to Rome, preceded by a proclamation, in which the general declared that the only object of his visit was the punishment of the murderers of Duphot and Bassville, and that the people of Rome should find in the French army protectors and friends. The revolutionary party, encouraged by this proclamation, actually proclaimed the Roman republic on the 15th of February 1798. Pius, however, resolved to make one more effort to preserve the government of the holy see from annihilation, and sent to Berthier, who was encamped without the walls of the city, his cardinal-vicar and other deputies, accompanied by the Neapolitan minister, who were instructed to negotiate for the continuance of his temporal existence, by the further sacrifices of provinces and of millions. His hopes were quickly dissipated by the peremptory refusal of the general to admit any other deputation than that of the Roman people. As the storm was approaching, some of the cardinals prudently fled from the city, but the majority waited the event, hoping, no doubt, to retain their rank and possessions, though probably at the expence of considerable sacrifices. For a short time they were treated with forbearance, but were obliged formally to abdicate their authority. After this, their estates were confiscated for the benefit of the nation, while the cardinals themselves were included under one common proscription, and confined as prisoners in a convent at Rome. From this prison they were sent to one, not so commodious, at Civita-Vecchia, where they were subjected to such menaces and insults, that the greater part of them were glad to purchase their liberty by the sacrifice of all their wealth. In the mean time the pope remained confined to his apartments at the Vatican, in anxious and trembling uncertainty with respect to his fate. That of his nephews, already mentioned, had been decided. The cardinal was a fellow sufferer with the other members of the sacred college, and the estates of the duke of Braschi were confiscated to the public use. His magnificent and sumptuous furniture, his pictures, engravings, antiquities, and his museum, were brought to the hammer. The estates and property of the pope himself were involved in the same confiscation with those of the cardinals: and the French commissaries, judging that his presence, in Rome, was incompatible with the tranquillity of the state, decreed that he should be sent beyond the boundaries of the Roman territory. Pius VI. was now escorted by a body of French cavalry to Sienna, where his first residence was in the convent of St. Barba, which he was obliged to quit by an earth-

quake that overthrew the apartments adjoining to those which he occupied, and damaged those in which he was. He now took up his abode within the walls of the city. In the month of May, he removed to a Carthusian convent within two miles of Florence. In this retired place Pius kept his little court, with great circumspection, to avoid giving umbrage either to the French or Tuscan government. He even offered to leave the nomination and regulation of his household to the inspection of the French minister. It was scarcely possible for papal humiliation to be carried much farther, for this minister happened to be a Protestant of the Lutheran persuasion. But stripped of his pontifical dignity, Pius is said to have exhibited an excellent example of christian-like resignation. He ever expressed a meek and forgiving disposition towards those who had despoiled him of his power and authority. Unembarrassed by the cares of government, his health became more stable, his spirits increased, and adversity seemed to prove to him the true road to happiness. He was not, however, allowed to enjoy the blessings of this state of humble retirement; the French directory enjoined the grand duke to dismiss him from the Tuscan territory: and it was decided by the republican tyrants that he should be sent to the island of Sardinia, where a papal conspiracy, if such an event should happen, must necessarily be circumscribed within very narrow bounds, but the attack of serious illness made his removal impossible. After his health was restored, he was permitted to remain in peace in the Carthusian convent, till the renewal of the war between France and Austria which had been terminated by the peace of Campo Formio, when it was resolved that he should be removed into the interior of France. In the course of a long and painful journey, frequently exposed to the insults of the illiberal and unfeeling, who could not but exhibit signs of exultation in the destruction of the papal power, he caught a feverish disorder which put an end to his sufferings on the 29th of August, 1799, being in the 82d year of his age. The French directory refused to his remains the accustomed sepulchral rites, but upon a change in the government of that country, the consuls of the republic ordered that he should be buried, with the honours commonly due to a person of his rank, and that a simple monument should be erected over the place of his interment, with an inscription expressive of the dignity which he bore. In 1802 his successor, Pius VII., obtained permission to remove his body to Rome.

"Pius VI." says the excellent writer of his article in the General Biography, to whom we have very frequently referred in our own, "though possessed of many estimable qualities as a private man, had few of those talents which are necessary to govern in times of difficulty and danger. Yielding often to the impulse of the moment, the impetuosity of his character led him into some errors, which were followed by a speedy repentance. Presumptuous with respect to his own opinion he was blind to the future, where men of common sagacity had the clearest foresight; and filled with ideas of the importance and dignity of his office, he prepared for himself many mortifications and insults, which he had neither the address to avoid, nor the power to avenge. As the visible head of the church, his attention to the duties of his station was uniform and exemplary, and his piety, though ostentatious, was devoid of hypocrisy or fanaticism, and his morals were pure and irreproachable. In his youth he had been one of the handsomest men of his time. To a very lofty stature he joined a noble and expressive set of features, a benign countenance, a sonorous voice, and an elegant engaging manner. Of these advantages he was but too sensible, and he betrayed a puerile vanity in displaying them on all public occasions, which exposed him

to many bitter farcafms, and which the ferioufly devout were at a lofs to reconcile with the acknowledged fanctity and gravity of his character." See alfo New Ann. Register. Monthly and Gent. Mag.

We beg leave, in this place, to correct an error in the article LEWIS XVI., vol. xx., in which the daughter of that unfortunate monarch is mentioned as having died in 1796. She was, we are happy to fay, living, at that time, in London; pitied and refpected for her misfortunes, and honoured and beloved on account of her many virtues.

PIUZANO, in *Geography*, a town of Italy, in Friuli; 14 miles W. of Gemona.

PIX, in *Coinage*, a box, in which a fmall proportion or fample of the coins ftruck at the mint is referved, in order to be affayed and compared with a check-piece or fandard kept in the exchequer for the occafion. This operation, which is called the "trial of the pix," is performed with great exactnefs in the prefence of the privy council, the officers of the mint, and a jury of the goldfmiths' company; and there is no inftance upon record of the coins thus tried being found to vary from the full fandard.

PIXITES, in *Ancient Geography*, a river of Afia, in the Colchide, towards the north of the town called Trapezus.

PIZARRO, FRANCISCO, in *Biography*, the discoverer and conqueror of Peru, was the natural fon of a Spanifh gentleman by a woman of the loweft rank. His father, not thinking himfelf bound to raife him to a condition fuperior to his maternal birth, not only left him deftitute of all education, but employed him in the fervile office of keeping fwine. Indignant at this treatment, he ran away and enlisted as a common foldier. After ferving fome time in Italy, he joined the adventurers who were embarkng at Seville for America. He was prefent in all the wars of Cuba and Hifpaniola, and upon every occafion he flood pre-eminent for undaunted courage, perfeverance, and enterprize, and was in a fhort time confidered as fully qualified for command. His mind and body were equally adapted for difficult and laborious undertakings, and experience had prepared him to meet all emergencies. In 1524, having acquired fome property, he, with Diego de Almagro, and Hernando Luque, entered into an affociation for the conqueft of the fupposed rich countries on the coaft of the South fea. Pizarro made the firft attempt. He failed in November from Panama in a fingle vefel with 112 men, fo feeble were the means by which the fubverfion of a great empire was to be effected. (See PERU.) Pizarro made feveral voyages, and with his affociates acquired the moft important conquefts, till at length the conquerors quarrelled among themfelves, and in April, 1538, the two hostile parties of Spaniards, each bearing the royal fandard, met and engaged with all the fury of inveterate foes, while an immense multitude of Indians, who had borne the cruelties of both, affembled on the furrrounding mountains, enjoying, to them, the edifying fpectacle of their favage foes deftroying each other by mutual flughter. The battle was fatal to the caufe of Almagro, who was himfelf taken prifoner after the total and bloody defeat of his troops. In a very fhort time the mercilefs Pizarro brought his old affociate to trial, condemned and executed him. Afterwards Pizarro was the unrivalled mafter of thefe extenfive regions, and without any regard to the Spanifh court, he divided them like a conqueror among his followers, fetting apart the moft valuable lots for himfelf, his brothers, and favourites. His partiality excited much difcontent among perfons, all of whom were actuated by the thirft of gain. The partizans of Almagro fighed in fecret for revenge; but as no open hostility was manifested, the plan of difcovery was carried on with vigour, and Gonzalo

Pizarro was difpatched by his brother upon the arduous enterprize of croffing the Andes, and exploring the countries to the east of that chain. It was on his return to Quito that he learnt the deftruction of his brother. The followers of Almagro had repaired in great numbers to Lima, where the fon of their late chief received them with much kindnefs, and engaged their warmeft attachment by his popular qualities. In their private meetings a confpiracy was formed againft the life of Pizarro. He was apprized of the fact, but, in the confidence of uncontrolled power, he difregarded them. The plot was, however, matured; and on the 26th of June 1541, at mid-day, a time, in thofe hot climates, devoted to refofe, Herroada, one of the principal of the Almagrian officers, at the head of eighteen determined affociates, sallied out armed from Almagro's houfe, and proceeded to the palace. They paffed unobferved through the outer courts, and were arrived at the foot of the ftaircafe before an alarm was given. Pizarro was in a large hall with fome friends. One of thefe who came to the top of the ftairs to enquire into the caufe of the tumult, was laid dead, while others efaped through the windows. The confpirators rufhed into the hall; Pizarro, with his half brother Alcantara, was killed, and the others mortally wounded: the former defended himfelf till he was abfolutely exhausted with fatigue, when, unable any longer to parry off the weapons, he received a thruft full in the throat, fell, and expired. His memory lives and ever will live as a fignal contributor to his country's aggrandizement, but blackened with the ftain of atrocious cruelty and perfidy. Univer. Hift. Robertfon's America.

PIZOLO, in *Geography*, a town of Sicily, in the valley of Noto; eight miles S. of Modica.

PIZZATI, GIUSEPPE, in *Biography*, published at Venice in folio, with a feparate volume of plates, in 1782, a treatife "On the Science of Sounds and of Harmony:" "La Scienza de' Suoni, e dell' Armonia." The author clearly explains the phenomena of found, as far as concerns practical mufic, from d'Alembert, another modern writer on harmonics, and gives an account of late difcoveries in the fciences, and of the fyftems of Rameau and Tartini, from Rouffeau, explaining the laws of harmony in their prefent ufe.

PIZZICATO, in *Italian Mufic*, from *pizzicare*, to pinch, is a term that announces to the performers on bowed inftruments the ufe of the fingers inftead of the bow. When the bow is to be refumed, it is expreffed by the words *con arco*.

PIZZIGHITONE, in *Geography*, a town of Italy, in the department of the Upper Po, on the Adda; nine miles N.W. of Cremona. N. lat. 45° 10'. E. long. 9° 48'.

PIZZO, a town of Naples, in Calabria Ultra, near the coaft; 13 miles N.E. of Tropea.

Pizzo Ferrato, a town of Naples, in Abruzzo Citra; 13 miles E.S.E. of Sulmona.

Pizzo di Gotto, a town of Sicily, in the valley of Demona; fix miles S. of Melazzo.

PLA, a town of Spain, in the province of Catalonia; five miles S. of Urgel.

PLABENNEC, a town of France, in the department of the Finifterre, and chief place of a canton, in the diftrict of Brest; feven miles N.E. of Brest. The place contains 3255, and the canton 11,833 inhabitants, on a territory of 230 kilometres, in 12 communes.

PLACAGNODIAUGIA, in *Natural Hiftory*, the name of a genus of fpars.

The word is derived from the Greek *πλαξ*, a *cruff*, *αργος*, *pure*, and *διευγνις*, *pellucid*.

The bodies of this genus are cryftalline terrene fpars, or fparry bodies with much of the brightnefs and tranfparence

of crystal, but debased by an admixture of earthy matter, and are imperfectly pellucid, and formed into thin plates with flat surfaces, but covered at times, either in part or entirely, with tubercles or botryoid prominences, and are composed of arrangements of oblong concretions, of no determinately angular figure.

Of this genus there are only two known species, *viz.* a hard semipellucid and yellowish-brown one, and a brittle pellucid and whitish one. Hill.

PLACAGNOSCIERIA, the name of a genus of spars.

The word is derived from the Greek *πλαξ*, a crust, *αγνος*, pure, and *οπισος*, opaque.

The bodies of this genus are dull and opaque crystalline terrene spars, formed into crusts, and of an irregular and not striated texture within.

Of this genus there are three known species, *viz.* a hard whitish-brown one, a dull crumbly whitish one, and a dull pale brown friable one, of a very coarse texture, which encrusts the sides and bottoms of vessels, in which water is frequently boiled. Hill.

PLACANICA, in *Geography*, a town of Naples, in Calabria Ultra; 27 miles E.S.E. of Reggio.

PLACARD, or PLACART, *Placaert*, a foreign term, frequent in gazettes, signifying a leaf, or sheet of paper, stretched and applied upon a wall, or post. Edicts, regulations, &c. are to be made public in placards.

The word placard is also used for a libel or lampoon. At Rome, placards against the pope are frequently fixed, in the night-time, to the statue of Pasquin. See PASQUINADE.

PLACARD, in *Architecture*, denotes the decoration of the door of an apartment, which is sometimes a corniche supported by consoles.

PLACARD, in our *Customs*, denotes a licence whereby a person is permitted to shoot with a gun, or to take otherwise unlawful game.

PLACCIUS, VINCENT, in *Biography*, a learned jurist, was born at Hamburg in the year 1642. After studying at Leipzig, and other places, he travelled into Italy and France, and became a licentiate in law at Orleans. Returning to his native city, he practised at the bar; and in 1675, was appointed professor of moral philosophy and eloquence, the duties of which he performed till his death, in 1699. He was author of a volume of Latin poems, and of many other works, of which the principal are, 1. A curious bibliographical piece concerning anonymous writers, first published at Hamburg in 1674, under the title of "De Scriptis et Scriptoribus anonymis atque pseudonymis Syntagma;" together with the "Catalogus Auctorum suppositiorum" of Rhodias. The work was well received, and he prepared a new edition of it, with considerable additions, which was printed after his death, in 2 vols. folio, in 1708, under the care of John Albert Fabricius. A supplement to it was published by Mylius, in 1740, at Hamburg. 2. "De Arte Excerptendi," 1689. Placcius has always been esteemed a learned and able writer, but his style is said to be obscure, and occasionally confused. Moreri.

PLACE, PETER DE LA, a learned French magistrate, and various writer, was born at Angoulême in the year 1526. He applied with success to the study of jurisprudence, and in 1548 published a Latin paraphrase on the Titles of the Imperial Institutes, "De Actionibus, Exceptionibus et Interdictis," in 4to. After this he was called to the bar of the parliament of Paris, and pleaded with so great success, that he acquired the character of a learned, eloquent, and virtuous counsellor. Francis I. ap-

pointed him advocate of his court of aids at Paris, and he discharged the duties of that office with so much talent and integrity, that Henry II. nominated him his first president in the same court. It was believed that he was a convert to the Protestant religion in the year 1554; but he did not make an open profession of it till the death of Francis II. On the breaking out of the civil war, he retired to one of his houses in Picardy; but upon the conclusion of peace in 1562, he seized the earliest opportunity of vindicating himself before the king from the several charges which had been preferred against him. He was now appointed by the prince of Condé superintendant of the household; and upon the rupture of that prince with the court, about the year 1566, M. La Place retired to the castle of Vè in the Valois, where he continued after the death of the prince, till Charles IX. granted the Protestants advantageous terms of peace in 1569, with the design of the more easily extirpating them. La Place, deceived by royal treachery, returned to Paris, and resumed the office of president to the court of aids, which he retained till he fell a victim in the horrible and accursed massacre of the Protestants, on St. Bartholomew's day, in the year 1572, at the age of 46. He is said to have possessed great soundness of judgment, clearness of discrimination, and a truly philosophic spirit, which admirably qualified him for the office of magistrate, and which were seldom found united in the professional men of that time. His chief works are, "Commentaries on the State of Religion, and of the Commonwealth, from 1556 to 1561;" "A Treatise on the right Use of Moral Philosophy in connection with the Christian Doctrine;" and "A Treatise on the Excellence of the Christian Man." Moreri.

PLACE, *Locus*, in *Philosophy*, that part of immoveable space which any body possesses.

Aristotle, and his followers, divide place into *external* and *internal*.

PLACE, *Internal*, is that space, or room, which the body contains.

PLACE, *External*, is that which includes or contains the body; which is also called, by Aristotle, the first or concave and immoveable surface of the ambient body.

It is controverted, in the schools, whether internal place be a real entity, or only an imaginary being; *i. e.* whether it be any thing intrinsically, or only an aptitude and capacity of receiving bodies.

Some maintain it a positive being, incorporeal, eternal, independent, and infinite; and assert it even to constitute the immensity of the godhead.

The Cartesians, on the contrary, hold internal place, abstractedly considered, to be no other than the very extension of the bodies contained in it; and therefore in no wise different from the bodies themselves.

The schoolmen likewise dispute, whether external place be moveable, or immoveable? Its immobility is argued from this consideration; that what moves, must necessarily leave its place; which it cannot do, if it go along with the moveable. Others charge an absurdity on this opinion of Aristotle; *viz.* that hence it follows, that a body really at rest is continually shifting place: a tower, for instance, on a plain; or a rock in the middle of the sea; because the one and the other, continually inclosed with new air, or new water, must be said to be in motion or to change place.

To solve this difficulty, and ward off the absurdity which follows from Aristotle's laying down external place as immoveable, many expedients have been had recourse to. The Scotists contend for place's being only immoveable, by equivalence. Thus, when the wind blows, the air which invested

vested the surface of the tower does indeed recede, but then other similar and equivalent air takes place. The Thomists choose to deduce the immobility of external place, from its keeping the same distance from the centre, and the cardinal points of the world; and the Nominalists, from a correspondence with certain virtual parts of the divine immensity.

The Cartesians deny external place to be either a surrounding surface, or a body surrounded, or a mean term between the two; and conceive it to be the situation of a body among adjacent bodies considered as at rest. Thus the tower shall be deemed to remain in the same place, though the ambient air be changed; since it retains the same situation with regard to the neighbouring hills, trees, and other parts of the earth.

Sir Isaac Newton better, and more intelligibly, distinguishes place into *absolute*, and *relative*.

PLACE, *Absolute*, and *primary*, is that part of infinite and immoveable space which a body possesses.

PLACE, *Relative*, or *secondary*, is the space it possesses, considered with regard to other adjacent objects.

Dr. Clarke adds another kind of relative place, which he calls *relatively common* place; and defines it, that part of any moveable or measurable space which a body possesses; which place moves together with the body.

PLACE, Mr. Locke observes, is sometimes likewise taken for that portion of infinite space possessed by the material world, though this, he adds, were more properly called extension.

The proper idea of place, according to him, is the relative position of any thing, with regard to its distance from certain fixed points; whence we say, a thing has or has not changed place; when its distance is, or is not altered with respect to those bodies.

For the vision of place, see VISION, and VISIBLE.

PLACE, in *Optics*, or *Optical Place*, is the point to which the eye refers an object.

Thus the points D and E (*Plate XVII. Optics, fig. 11.*) to which two spectators in *d* and *e* refer the object C, are called *optic places*.

Here, if a right line joining the optic places D and E, be parallel to a right line passing through the eyes of the spectators *d, e*; the distance of the optic places D, E, will be to the distance of the spectators *d* and *e*, as the distance of one of the optic places from the place of the object E C, to the distance of the other spectator from the same object *dC*.

PLACE, *Optic*, of a star, is a point in the surface of the mundane sphere, as C or B (*Plate XVIII. Astronomy, fig. 4.*), wherein a spectator in E, or T, sees the centre of the star S.

This is divided into *true* and *apparent*.

PLACE, *True*, or *real optic*, is that point of the surface of the sphere B, in which a spectator, placed in the centre of the earth, sees the centre of the star, or phenomenon. Or, it is a point among the fixed stars, determined by a line drawn from the centre of the earth through that of the star, and terminated in B among the stars.

PLACE, *Apparent*, or *visible optic*, is that point of the surface of the sphere, in which a spectator, placed on the surface of the earth in E, sees the centre of the star S. Or, a point C found by a line passing from the spectator's eye through the star, and terminated in the sphere of the stars.

The distance between the two optic places makes what we call the *parallax*.

The *apparent* place, in optics, is different from the *real* one; for when, by refraction through glasses, that parcel of rays which falls on the pupil of the eye, from each point

of any near object, is made to flow as close together, as that which comes from a distant one; or when, by the same means, the rays coming from distant objects are made to diverge as much as if they flowed from near ones; then the eye must necessarily see the place of the object changed; which change is its apparent place.

If an object be placed nearer to a convex glass than is the distance of its focus, its apparent place may be determined; but if the object be in the focus of the glass the *locus apparentis* of the object cannot be determined; only that it will appear vastly remote.

Nor can the *locus apparentis* be determined if the object be beyond the focus of the convex glass; but if the object be farther distant from a convex glass than its focus, and the eye lie beyond the distinct base, its apparent place will be in the distinct base. See LENS.

PLACE of the sun, a star, or planet, simply, denotes the sign and degree of the zodiac, which the luminary is in.

Or, it is that degree of the ecliptic, reckoned from the beginning of Aries, which the planet's or star's circle of longitude cuts; and therefore it coincides with the longitude of the sun, planet, or star.

As the sine of the sun's greatest declination $23^{\circ} 30'$: to the sine of any present declination given or observed, *v. gr.* $23^{\circ} 15'$: so is radius 10: to the sine of his longitude $80^{\circ} 52'$, which, if the inclination were north, would give $20^{\circ} 51'$ of Gemini, if south, $20^{\circ} 52'$ of Capricorn, for the sun's place.

PLACE, *Astronomical*. See ASTRONOMICAL.

PLACE, *Moon's*, is that point of her orbit in which she is found at any time.

This, by reason of the great inequalities in the lunar motions, which render a number of equations and reductions necessary before the just point be found, is of various kinds.

PLACE, *Excentric*, of a planet in its orbit. See EXCENTRIC, and P, *Plate XVI. Astron. fig. 148.*

PLACE, *Heliocentric*, of a planet. See HELIOCENTRIC, and R, *fig. 148.*

PLACE, *Geocentric*. See GEOCENTRIC, and R, *fig. 148.*

PLACE of Radiation, in *Optics*, is the interval, or space in a medium or transparent body, through which any visible object radiates.

PLACE, in *Geometry*, is a line used in the solution of problems; more usually called by the Latin name *locus*.

See the doctrine of geometrical places under LOCUS.

PLACE, in *War*, is a general name for all kinds of fortresses, where a party may defend themselves.

In which sense it may be defined to be a place so disposed, as that the parts which encompass it defend and flank one another.

PLACE, *Strong*, or *fortified*, is a place flanked and covered with bastions. See FORTIFIED PLACE.

PLACE, *Regular*, is that whose angles, sides, bastions, and other parts are equal; and this is usually denominated from the number of its angles; as a pentagon, a hexagon, &c. Palma Nova, built by the Venetians, is a dodecagon.

PLACE, *Irregular*, is that whose sides and angles are unequal.

PLACE of Arms, in *Fortification*, is a strong city or town, pitched upon for the chief magazine of an army.

PLACE of Arms, in a city or garrison, is a large open spot of ground, usually near the centre of the place, where the grand guard is commonly kept, and the garrison holds its rendezvous at reviews, and in cases of alarm, to receive orders from the governor.

PLACE of Arms, of an attack, in a siege, is a spacious place covered from the enemy by a parapet or epaulement, where

where the soldiers are posted ready to sustain those at work in the trenches, against the soldiers of the garrison. It is customary to make three places of arms, when the ground will permit; the first and most distant from the place is about three hundred toises from the glacis of the covert way; the second is within one hundred and forty toises; and the third at the foot of the glacis. See PARALLELS.

PLACE of Arms particular, in a garrison, is a place near every bastion, where the soldiers, sent from the grand place to the quarters assigned them, relieve those that are either upon the guard, or in fight.

PLACE of Arms without, is a place allowed to the covert-way, for the planting of cannon; to oblige those who advance in the approaches to retire.

Those places of arms that are in the covered way, are places made at the entering and salient angles, considerably larger than the street of the covered way, and formed by turning the head of the glacis into two faces, projecting towards the country: those at the salient angles are formed by the rounding of the counterscarp; those at the entering angles are constructed by taking the gorges at the head of the glacis of a certain length, drawing the faces at a certain angle, and parallel to those faces drawing a glacis.

PLACE of Arms, in a camp, is properly the bell-tents at the head of each company, where the arms are lodged. It also denotes a large space at the head of the camp, for the army to be ranged in and drawn up in battalia.

PLACE of Arms of a troop or company, is the spot of ground on which the troop, or company, draws up.

PLACE, Face of a. See FACE.

PLACE, Tenaille of the. See TENAILLE.

PLACE, View of a. See VIEW.

PLACE, Fire. See FIRE-PLACES.

PLACE, among logicians and orators, denotes the seat or source of an argument; or that from which it is taken.

PLACE is used in the doctrine of artificial memory: and these places may be either such in a proper sense, as a door, a window, a corner, &c. or familiar and known persons; or any thing at pleasure, provided that they be placed in a certain order, animals, plants, words, letters, characters, historical personages, &c. though some of these are more and some less fit for the purpose; but such kinds of places greatly help the memory, and raise it far above its natural power. See MEMORY and MNEMONICS.

PLACE, Common. See COMMON PLACE.

PLACE of Units, Tens, &c. See UNIT and NUMERATION.

PLACES, Hylegial, in Astrology. See HYLEGIAL.

PLACE, Whispering. See WHISPERING.

PLACE, Additions of. See ADDITION.

PLACE, Unity of. See UNITY.

PLACE Bricks, were kiln-burnt red bricks of a full size, now entirely disused in the metropolis; but in lieu of them, the soft insufficiently burnt bricks from the outside of the clamps are called, by way of distinction from stock or hard burnt bricks, place bricks. These are of a foul red colour, and will easily break or crush to pieces. The particular manner in which place bricks were formerly made was by dipping the mould in water before the clay was put in; which made the outer surfaces when burnt very coarse and hard. See BRICK.

PLACENTA, in *Anatomy*, a vascular spongy body, containing the ramifications of vessels from the uterus, and of others from the foetus, and forming the medium by which the mother and child are connected. See GENERATION.

PLACENTA, in *Natural History*, the name of one of the classes of the echini marini. The characters of these are,

that they are of a depressed or flattened form, and are wrought in various shapes, as the pastry people make their cakes; they all have a cinquefoil flower at their top, and their mouth is in the middle of the base; the aperture for their anus is usually near the edge.

Of this class there are three genera: 1. The melitta. 2. The laganum. And 3. The rotula: which see under their several heads.

PLACENTA, among the *Ancients*, a kind of cheese-cake, the most simple kind of which was made of flour mixed with oil and cheese, to which honey was added: but the more luxurious sort of people added likewise a great variety of fruits, as also sugar, eggs, butter, &c.

PLACENTIA, or *PIACENZA*, in *Geography*, a city of Italy, and capital of a duchy annexed to Parma, on the S. side of the Po. This city was built and colonized by the Romans about 218 years B.C., and not long after, served as an asylum to the Roman army, when defeated by Hannibal at the Trebia. It was afterwards assaulted by that Carthaginian general, without success. This city became very flourishing and municipal, but it suffered much in the troubles that attended the elevation of Otho to the empire; and when attacked by a party of the Vitellians, it effectually resisted, and in the bloody contest had only to lament the loss of its amphitheatre, remarkable for its capaciousness and architecture, which was set on fire and reduced to ashes. Placentia, after having frequently changed masters, was annexed to Parma, and thus remained till the expulsion of the late duke, when, with the whole of its territory, it was occupied by the French. It is a large and well built city. Its cathedral is Saxon; the town-house, with some other public buildings in the great square, Gothic. Several churches, particularly that of St. Agostino, are of fine Roman architecture, and some of them adorned with paintings of great celebrity. The great square is ornamented with two brass equestrian statues, one of Alexander Farnese, and the other of his brother Ranuccio, which are much admired, particularly the former, for attitude, animation, and drapery. The streets of Placentia are handsome, broad, and straight: one in particular, called the Stradone, is reckoned the longest and most beautiful in Italy, being 3000 feet in length. Placentia is a bishop's see, and contains, besides the cathedral, 1 collegiate, 12 parochial, and 38 other churches, 8 abbeys, 16 convents, and an university. The number of inhabitants is about 20,000, including 2000 ecclesiastics. The neighbourhood of Placentia is, perhaps, more interesting than the town itself, as it was the theatre of many bloody engagements. The duchy is about thirty miles long from N. to S., and from 8 to 15 broad from E. to W.; the soil is fertile, and furnishes mines of iron, copper, and vitriol; 52 miles S.E. of Milan. N. lat. 45° 3'. E. long. 0° 43'.

PLACENTIA Bay, a spacious bay on the S. coast of Newfoundland, which forms a good harbour for ships, and is frequented by ships employed in the cod-fishery, and by those that are bound into the gulf or river St. Lawrence. It opens between Chapeau Rouge Point W. and cape St. Mary's on the E., 15½ leagues apart; lying between N. lat. 46° 43' 30" and 47° 54', and between W. long. 54° 1' and 55° 21' 30". The port-town, which gives name to the bay, is on the eastern shore; 67 leagues to the E. of the island of Cape Breton, 40 miles W. by S. of St. John's, in N. lat. 47° 15' and W. long. 55° 13'. The harbour is so capacious, that 150 sail of ships may lie in security, and fish as quietly as in any river. The entrance into it is by a narrow channel, which will admit but one ship at a time. Sixty sail of ships can conveniently dry their fish on the Great Strand, which lies between two steep hills, and is about three miles long.

long. One of the hills is separated from the strand by a small brook, which runs out of the channel, and forms a fort of lake, called the Little Bay, in which are caught great quantities of salmon. The inhabitants dry their fish on what is called Little Strand. The French had formerly a fort called St. Louis, situated on a ridge of dangerous rocks, which contracts the entrance into the harbour. In going in the ridge must be left on the starboard.

PLACENTIA *Lagoon*, a bay on the coast of Yucatan. N. lat. $18^{\circ} 38'$. W. long. $89^{\circ} 40'$.

PLACENTIA *Island*, an island near the coast of Maine. N. lat. $44^{\circ} 10'$. W. long. $68^{\circ} 10'$.

PLACER *de Abraxas*, a rocky islet, near the S. coast of Cuba. N. lat. $21^{\circ} 18'$. W. long. $80^{\circ} 52'$.

PLACETTE, JOHN DE LA, in *Biography*, an eminent French minister and moralist, was born at Pontac, in Bearn, in the year 1639. He received the early part of his education under his father, who was minister of his native place; and after he had made good proficiency in the classics and the belles-lettres, he applied to the studies requisite to qualify him for the profession of a divine. His first settlement was with the church of Orthès in Bearn; from which he removed, in about four years, to that of Nay, in the same province. Here he continued till the year 1685, when the revocation of the edict of Nantes compelled him to renounce his country for an asylum among strangers. He now gladly accepted an offer made him by the queen of Denmark, to become pastor of a French church, which she had founded at Copenhagen. He enjoyed the favour and patronage of that illustrious princess till her death, in 1711, when he removed into Holland. Here he first resided at the Hague, and afterwards at Utrecht, where he died in 1718, in the 80th year of his age. His works are very numerous, of which some of the chief are as follow: "New Moral Essays," in 6 vols. 12mo.; "A Treatise on Conscience," which was translated into English by Basil Kennet, under the title of "The Christian Casuist;" "A Treatise on Oaths;" "A Treatise on the Games of Chance;" and "A Compendium of Christian Morality," of which the best edition is said to be that of 1701. The character of this writer is thus drawn: "His knowledge was extensive, his penetration lively, and his judgment calm and dispassionate. His disposition was benevolent, his manners affable, and his charity was extended to Christians of all communions. With great clearness of perception, and soundness of judgment, he has very happily disentangled and elucidated the most intricate and embarrassed questions. Less profound than Nicole, and less ingenious than Rochefaucault, he will please good men by his solid morality, equally removed from excessive rigour and criminal remissness." His style, as a writer, is simple and equitable, though frequently diffuse. Moreri.

PLACIA, in *Ancient Geography*, a town of Asia Minor, in Mysia, on the borders of the Propontide, between Pannormus to the W., and the mouth of the Rhyndacus to the E. According to Pomponius Mela, and also Herodotus, this town was colonized by the Pelasgi. Cybele was held in great veneration in this place, and as Cyzicus was very near it, the Cyzicanians worshipped her under the name of the "Mother Placia."

PLACIDE, in *Biography*, a French monk, celebrated as an able geographer, was, probably, born at Paris in the year 1648. He was nearly related to, and pupil of, Peter Duval; and, at the age of 18, embraced the religious life in the convent of the Augustinian bare-footed friars, at the Place des Victoires. Here he appears to have made geography the principal pursuit of his life, and drew several

maps and charts that were highly esteemed, of which the most celebrated is that of "The Course of the River Po," consisting of several sheets. On account of his great skill and ingenuity in this branch of science, he was, in 1705, appointed geographer in ordinary to the king. He died in 1734, at the advanced age of 86. An engraved likeness of this able man is sometimes to be met with as a frontispiece to collections of his maps. But the monks of his fraternity obtained possession of the plate, and destroyed it, out of resentment to Placide, who refused to submit to their newly adopted fashion of being shaved; and he is represented in the engraving as wearing a beard. Moreri.

PLACIDIA, a Roman empress, the daughter of Theodosius the Great, by his second wife Galla. She was born about A.D. 388, and was brought up in the palace of Constantinople. When her brother Honorius was seated upon the throne of the western empire, she took up her residence in Rome, and was in that capital when it was invested by Alaric in 408. At the third siege and sack of Rome in 410, Placidia was one of the captives whom the conqueror carried away with him; she was, however, treated with the respect due to her rank and sex. After the death of Alaric, Ataulphus, who succeeded him as king of the Goths, refused to restore her, and at length made proposals of marriage to her. She submitted, says Gibbon, without reluctance to the desires of the conqueror, a young and valiant prince, who yielded to Alaric in loftiness of stature, but who excelled him in the more attractive qualities of grace and beauty. The marriage of Ataulphus and Placidia was consummated before the Goths retired from Italy. The bride, attired and adorned like a Roman empress, was placed on a throne of state, and the king of the Goths, who assumed on this occasion the Roman habit, contented himself with a less honourable seat by her side. The nuptial gift, which, according to the custom of the nation, was offered to Placidia, consisted of the rare and magnificent spoils of her country. Fifty beautiful youths, in silken robes, carried a basin in each hand, and one of these basins was filled with pieces of gold, the others with precious stones of inestimable value. These, however, formed an inconsiderable portion of the Gothic treasures. She brought forth a son, who soon died, and shortly after, in 415, Ataulphus was murdered by one of his domestics in Spain. Singeric, who usurped the Gothic throne, treated Placidia with great ignominy, and obliged her to walk twelve miles before his chariot with a crowd of other captives; but Singeric was assassinated a few days after his elevation. By a treaty between the Romans and Goths, she was afterwards ransomed at an immense price, and returned to Italy. In 417, her brother Honorius, as a reward for the services of his general Constantius, compelled her to give him her hand in marriage. She manifested great reluctance to this union, which, nevertheless, was productive of a son and daughter, named Valentinian and Honoria. Placidia again became a widow in 421, after her husband had occupied the throne only seven months. After this Placidia fought for herself and children a retreat at Constantinople, where she was honourably received by her nephew Theodosius, who granted to Placidia the title of Augusta, and to her son that of Cæsar. In 425, Placidia again recovered her authority, and assumed the reins of government, as regent, during the minority of her son. Her administration was not remarkable for wisdom or vigour, and she has been charged with the despicable and criminal policy of corrupting her son by a dissolute education, that she might the longer keep the power in her own hands. At any rate, she seems to have governed with absolute sway till her death,

at

at the age of 62, in the year 450. She was interred at Ravenna, where her tomb, and even her corpse seated in a cypress chair, were preserved for many ages. This empress received many compliments from the orthodox clergy, and St. Peter Chryfologus assured her, that her zeal for the Trinity had been recompensed by an august trinity of children. Univer. Hist. Gibbon, vols. v. and vi.

PLACITA, **PLEAS**, a term frequent in our laws and customs. Originally, placita signified certain public assemblies of all degrees of men, in which the king presided, and where the great affairs of the kingdom were consulted upon.

These assemblies were called *placita generalia*; because *generalitas univerforum majorum tam clericorum quam laicorum ibidem conveniebat*. And hence the decrees, ordinances, sentences, &c. of this assembly, were also called *placita*.

Sim. Dunelmensis tells us, they were held in the open fields; for, says he, *nullam oportet regem in literis assignare curiam, quia ubi rex judicat in aperto ibi est curia sua*.

Some will have these *placita generalia*, and *curie regis*, of ancient times, to be much the same with what we now call a *parliament*.

The lords courts came hence also to be called *placita generalia*, though oftener *curie generalis*; because all their tenants and vassals were obliged to appear in them.

We also meet with *placitum nominatum*, for the day appointed a criminal to appear in, and make his defence. Leg. Hen. I. And *placitum fractum*, i. e. when the day is lapsed.

Lord Coke derives the word *placitum* à *placendo*, *quia beneplacitare super omnia placet*: indeed, this seems a very fanciful etymon; and others have more reason in deriving the word from the German *platz*, or the Latin *plateis*, *fields*, or *streets*, where these assemblies were originally held.

PLACITARE, in the old *Law Books*, signifies to plead causes. See **PLEADING**.

“Mos placitandi, ante Conquestum, fuit coram aldermanno, et proceribus, et eorum hundredariis, sc. baronibus, majoribus, melioribus, senioribus, et urbanis.” Misc. in Bibl. Cott. sub. tit. Vitellius.

Hence, *placitator*, a *pleader*. Ralph Flambard is recorded to have been *totius regni placitator*, in William II.'s time.

PLACITUM, in *Law*, a sentence of the court; or an opinion, ordinance, or decree.

Custos PLACITORUM corone. See **CUSTOS**.

PLACKET, or **PLAQUETTE**, in *Commerce*, a small silver coin of the Netherlands, of $3\frac{1}{2}$ stivers current. The old plaquettes have been reduced to $2\frac{1}{2}$ stivers. The assay of the placket is W. (worse than the English standard) 5 oz. 8 dwt.; its weight, 1 dwt. 18 gr.; its contents in pure silver grains, 20: and its value in sterling, or. $2\frac{3}{4}d$.

PLACODIUM, in *Botany*, from *πλακωδης*, *broad and crustaceous*, a division of the natural order of *Lichenes*, as first distributed by Hoffmann, and constituting the fourth section of his seventh genus, *Lobaria*. It composes the second tribe in the *Prodromus* of Acharius, but has no part in the subsequent arrangement, published in his *Methodus*. See **LICHENES**.

PLACUS, from *πλακω*, *a cake*, because the inhabitants of Cochinechina use the fragrant juice of the genus in question, as an ingredient in cakes.—Lour. Cochinch. 496.—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Composita nucamentacea*, Linn. *Corymbifera*, Juss.

Gen. Ch. Common calyx imbricated, inversely turbinate,

scales linear, slender, erect. *Cor.* compound, equal to the calyx, erect; *florets* of the disk few, all perfect, tubular, five-cleft; those of the circumference very numerous, naked. *Stam.* (in the perfect florets) Filaments five, very short; anthers forming a cylindrical tube. *Pist.* (in all the florets) Germen oblong; style thread-shaped, short; stigmas two, oblong, erect in the perfect florets, reflexed in the female ones. *Peric.* none, except the unchanged calyx. *Seed* to each of the florets oblong, most slender in the female ones; down capillary. *Recept.* naked, convex.

Eff. Ch. Receptacle naked. Down capillary. Calyx imbricated, inversely turbinate, with linear scales. Florets of the radius without a corolla.

1. *P. tomentosus*. Lour. n. 1.—Leaves ovate, obtuse, downy on both sides. —Found wild, as well as cultivated, in Cochinechina. *Stem* herbaceous, two feet high, erect, branched. *Leaves* alternate, sessile, ferrated, odoriferous. *Flowers* violet, in terminal, erect, oblong panicles.

2. *P. levis*. Lour. n. 2.—Leaves ovate, pointed, smooth. Native of the same country.—*Stem* not quite so tall, smooth. *Flowers* pale yellow, in short terminal panicles. *Calyx* tumid at the base. We know nothing of these plants but from the account of Loureiro. See **ELICHRYSUM**, **GNA-PHALIUM**, and **ERIGERON**.

PLADAROTIS, from *πλαδαρος*, *fluid*, in *Surgery*, a fungous tubercle upon the inside of the eye-lid.

PLADIA, or **BLADIA**, in *Geography*, a town of Prussia, in the province of Natangen; 22 miles S.W. of Konigsberg.

PLADLING, a town of Bavaria, situated on the Iser; 8 miles N.W. of Oltershofen.

PLAFOND, or **PLATFOND**, in *Architecture*, the ceiling of a room, whether it be flat or arched; lined with laths and plaster, and sometimes also enriched with paintings, &c. See **CEILING**.

PLAFOND is also more particularly used for the bottom of the projecture of the larnier of the cornice; called also the *soffit*.

PLAGALIS, Lat. *πλαγίος*, *obliquus*, à *latere*. *Plagal* and *authentic*, in the ecclesiastical modes, or *canto fermo*, imply the different divisions of the octave: the division is called *authentic*, when the 5th is in the acute; and *plagal*, when the 4th is in the grave. (See **PLAIN CHANT**, and **MODES**, *Ecclesiastical*.) The terms *authentic* and *plagal* are with reason censured by Meibomius and Bontempi as barbarous. Bontempi proposes, instead of the word *authentic*, to substitute *principal*; and for *plagal*, *relative* or *collateral*. These distinctions in the Roman church are similar to the discriminations made by the Greek musical writers where they class their modes under the denominations of *principal* and *subordinate*, with the distinction of *hyper* and *hypo*. It is not surprising that the primitive Christians should give Greek names to the species of octaves in imitation of the Greek modes; nor, if we reflect on the simplicity that was aimed at, and the humble state of those who first employed music in their religious worship, shall we wonder at the incorrect and artless manner in which it was done. How the Roman church acquired Greek terms in *canto fermo* it is easy likewise to imagine, if we recollect that it was a present from Greek fathers: and Gregory, in reforming the mass, not only retained these Greek terms, but adopted others, both from the Greek and Hebrew languages and ceremonies, in order to conciliate parties, and acquire converts: as *Kyrie Eleison* from the Greek, and *Hallelujah* from the Hebrew.

PLAGIANTHUS, in *Botany, so called by Forster, from *πλαγίος*, *oblique*, and *ανθος*, *a flower*, because of the oblique disposition of the petals, which gives the flower an irregular*

irregular appearance.—Forst. Gen. t. 43. Schreb. 459. Willd. Sp. Pl. v. 3. 719. Mart. Mill. Dict. v. 3. Juss. 274.—Class and order, *Monadelphia Doddecandria*. Nat. Ord. *Columnifera*, Linn. *Malvaceæ*, Juss.

Gen. Ch. Cal. Perianth simple, of one leaf, inferior, bell-shaped, with five small acute segments. Cor. Petals five, obovate, rounded, with claws, two of them folding over each other, at a distance from the rest. Stam. Filaments united into a cylinder, the length of the petals; anthers about twelve, ovate, crowded about the top of the cylinder. Pist. Germen superior, ovate, very small; style thread-shaped, concealed within the tube of the stamens; stigma club-shaped. Peric. Berry Seeds

Ess. Ch. Calyx simple, five-cleft. Petals five; two of them together, remote from the rest. Style one; Stigma club-shaped. Berry

1. *P. divaricatus*. Forst. Prodr. 47. Willd. n. t.—Found by Forster in New Zealand.—A shrub, with alternate, smooth, slender branches, clothed with a smooth, shining, purplish-brown bark. Buds alternate, of two or three brown membranous scales. Leaves three or four from each bud, linear, somewhat obovate, bluntish, with a little point, entire, smooth, about half an inch long, tapering at the base, but scarcely stalked. Flowers solitary, adjoining to the leaf-buds, whitish, each on a recurved smooth stalk, not half the length of the leaves. We have, like Willdenow, merely seen one of Forster's dried specimens. Nothing can bear much less resemblance to a malvaceous plant, except that the inner bark seems fibrous. Willdenow most truly remarks that this genus has nothing in common with *Conarus*, to which it seems, by a manuscript note of the younger Linnæus, some great botanists had referred it.

PLAGIARA, or PLAGIARIA, in *Ancient Geography*, a town of Spain, in Lusitania, upon the route from Olisipo to Emerita, between Emerita and Budua, according to the Itinerary of Antonine.

PLAGIARY, in *Philology*, *Author-theft*; or the practice of purloining other people's works, and putting them off for a man's own.

Among the Romans, *plagiarius* was properly a person who bought, sold, or retained a freeman for a slave; so called, because the Flavian law condemned such a person *ad plagas*, to be whipped.

Thomasius has an express treatise *de plagio literario*; wherein he lays down the laws and measures of the right which authors have to one another's writings. Dictionary writers, at least such as meddle with arts and sciences, seem in this case to be exempted from the common laws of *meum and tuum*; they do not pretend to set up on their own bottom, nor to treat the reader at their own cost. Their works are supposed, in great measure, compositions of other people; and whatever they take from others, they do it avowedly. In effect, their quality gives them a title to appropriate every thing that may be for their purpose, wherever they find it, and they do no otherwise, than as the bee does, for the public service.

Their occupation is not pillaging, but collecting contributions; and, if you ask them their authority, they will produce you the practice of their predecessors of all ages and nations.

PLAGIAULUS, Πλαγιαυλος, among the *Ancients*, a kind of flute.

PLAGIOPATEUS, in *Natural History*, a term used by Artedi and others, to signify depressed, in opposition to the term cathoptateus, which signifies compressed.

PLAGIUM, in *Civil Law*, the offence of spiriting

away and stealing men and children: whence the offenders were called *plagiarii*, and were punishable with death. See KIDNAPPING.

PLAGIURI, in *Natural History*, the name of one of the great classes, or families of fish: the characters of which are, that the tail is placed horizontally; they respire by means of lungs, and have usually a double fistule in the head; they are viviparous, and the males have a penis and testes, the females the vulva, ovaria, mammae, &c. and they bring up their young with milk.

The term is derived from the Greek πλωγιος, *transverse*, and ουρα, *a tail*.

Under this class of fish are comprehended the following genera: the physeter, delphinus, balæna, monodon, catodon, and trichechus; which see under their respective articles.

PLAGUE, λοιμος, *Pestis*, in *Medicine*, called also *pestilence*, *pestilentia*, *pestilitas*, a term which has been applied to various epidemic and fatal diseases, but is now limited by physicians to a contagious and malignant fever, which is accompanied by buboes and carbuncles.

Some corresponding appellation is to be found in all languages by which an extensive and destructive malady of this kind is designated. There is little doubt, however, that these raging epidemics have consisted of different maladies in different instances; having been sometimes the remittent fever originating from marsh effluvia, sometimes the true plague, and sometimes perhaps the small-pox, or scarlet fever; occasionally, too, even the *ignis sacer*, or epidemic land-scurvy, the result of a dearth of nutriment, appears to have been denominated pestilence. (See *IGNIS SACER*.) In many instances, the plagues described by historians are only depicted by the extent of the mortality and misery which they carried with them, and their peculiar symptoms are not detailed; so that it is impossible to ascertain the nature of the malady itself. And in some cases, though the phenomena of the disease are partially described, yet the general description is obscure and doubtful. Such is the character of the striking history of the plague at Athens, which has been left by Thucydides: it seems to be sufficiently distinct to prove that that epidemic was not the true plague; since the glandular swellings were not among the symptoms. The description of the state of the skin, indeed, impresses the notion of small-pox, rather than of any other contagious disease; for it is said to have been "red-dish or livid, with an eruption of *small pustules and sores*." (Πλευραίναις μικραῖς καὶ ἔλκυσιν ἰξνηθῆκος. Thucyd. lib. ii. § 49.) But some of the symptoms apparently belong to the *ignis sacer*. Lucretius has given a poetical translation of this history of the plague, as detailed by Thucydides. (Lib. vi.) Some of the plagues mentioned by Livy, as occurring among the Romans, do not appear to have been accompanied by the glandular tumours and carbuncles of the true plague.

In more modern times, the various forms of pestilence have been somewhat more accurately distinguished; and during the fifteenth, sixteenth, and seventeenth centuries, various countries both of Europe and Asia have been afflicted with the visitations of the true plague; so that its form and character have been but too well recognized. We shall endeavour to collect into one view the various appearances which it exhibits.

The nosological definition of the plague given by Dr. Cullen, is "a typhus fever, in the highest degree contagious, and accompanied with extreme debility. On an uncertain day of the disease there is an eruption of buboes or carbuncles." (Nosol. Method. Gen. 30.) On the whole, this

PLAGUE.

this brief character of the disease is as correct as any that can be given; for, in fact, the disease varies greatly in its appearances in different instances; inasmuch that even fever is by no means invariably present; and in the more fatal cases of plague, death terminates its course, before a sufficient time has elapsed to admit of the formation of buboes and carbuncles.

It is not easy to give a general history of the symptoms of the plague; because, in its different degrees of violence, its course and character exhibit very material variations. Hence it has been the practice of almost all the physicians, who have published their observations on the disease, to divide the congeries of symptoms into several classes: the physicians of Marseilles described five species of the malady, and Dr. Russell divided it into six; while Lange, Oræus, and others, speak only of three types which it assumed, or three degrees of violence, the mild, severe, and malignant.

The general derangement of the system, which ushers in an attack of the plague, is much like that which commences the course of ordinary fever. A sense of cold, with some shivering, which is soon followed by heat, and acceleration of the pulse, with giddiness, head-ache, depression of strength and spirits, white tongue, vomiting, or diarrhœa, and great oppression about the præcordia, are among the first symptoms of the disease. These are succeeded by a burning pain about the pit of the stomach, by a peculiar muddiness of the eyes, by coma, delirium, and other affections of the sensorium, which terminate by death in some cases on the second or third day, before the pathognomonic symptoms, buboes, and carbuncles, have appeared; but which, in others, continue to increase, while these morbid changes ensue, together with purple spots and ecchymoses, which belong to the plague, in common with other malignant fevers. Without attempting a description of the different classes of the plague as subdivided by the writers above-mentioned, we shall follow the laborious Dr. Russell through some of his remarks on the particular symptoms, as he observed the disease at Aleppo.

The fever is present at one stage or other of the plague with very few exceptions, though it differs materially in its degree, duration, and symptoms, in different individuals. It is usually preceded by a weariness and a confusion of head, which becomes a severe pain as the fever advances. The cold stage is short, and less marked than in an intermittent; but the changes in the succeeding hot fit are sudden, anomalous, and alarming. Nausea and vomiting frequently occur from the beginning; but these symptoms are absent in a large proportion, even in cases which terminate fatally. Indeed in many the attack is scarcely to be distinguished from that of ordinary fevers before the second night, unless where buboes and carbuncles arise within the first twenty-four hours. Although these remove all doubts about the nature of the fever, they do not, however, afford any certain prognosis of the event of the disease. In some cases clear remissions occur on the second or third day; but in general the changes from better to worse are frequent in the course of the first twenty-four hours, and more sudden and various than in common fevers. The disease in most cases advances with extreme rapidity, inasmuch that the patient on the second or third day is often in point of debility, disorder of the senses, and of the vital functions, reduced apparently to the condition of one in the last stage of a malignant fever; yet to this desperate state will succeed a remission, in which his senses and intellectual faculties are restored, and weakness only seems to remain. Nevertheless, these remissions, when occurring early in the disease,

or when not preceded by a sweat, are often short and fallacious: but when they follow a perspiration on the third day or later, and are of some hours continuance, they afford hopes of a favourable issue.

Delirium in the plague seldom becomes so violent and parientic, as in some other fevers. It sometimes comes on the first night, but in general not before the second; and is highest in the febrile exacerbations. Sometimes delirium alternates with coma, which last is in general a more dangerous symptom, but most particularly so when it comes on early, and does not abate in the remissions.

The change in the *eyes*, which has been described as a *muddiness*, is extremely remarkable. It sometimes takes place on the first day, but more commonly on the second or third, and remains till some favourable turn of the disease occurs. "It resembled somewhat the dull fixed eye observable in the last stages of malignant fevers, but the dullness was different, muddiness and lustre being strangely blended together:" and Dr. Russell adds, that it contributed much to that confusion of countenance, which enabled him, after a little experience, to pronounce with tolerable certainty on the existence or nonexistence of the plague. The *tongue* very often retains its natural appearance; and where it change its colour, it becomes only white, and remains moist, seldom becoming parched, and never putting on so thick a fur, or assuming so dark a colour, as in the advanced stages of some other fevers. The *pulse* is generally low, quick, and equal; and in the latter stages it becomes exceedingly quick and small, especially during the exacerbations, so as to be scarcely perceptible; yet in some cases, when the disease is considerably protracted, and other symptoms denote much disorder, the pulse varies little from its natural state. In fact, the variations of the pulse are often quite incongruous with the other symptoms. The respiration is little disordered, except in the advanced stage: there is no labor of the breath, nor cough; but there is an extreme anxiety and oppression about the præcordia, which produce great inquietude, and where they come on early, always dangerous symptoms. They are often accompanied by a pain and distressing sense of heat in the epigastrium, probably connected with the stomach, and rather increased than relieved by the vomiting.

The functions of the brain and nerves are particularly affected by the attack of the plague; so that a sudden and extreme prostration of strength belongs to the disease under all circumstances, and is, in fact, the most marked characteristic of its severe and fatal forms; the vital principle appearing to be suddenly as it were extinguished, or so enfeebled at once as to be incapable of resisting the violence of the disorder.

Vomiting did not occur in a very large proportion of the sick at Aleppo: but where it appeared at the beginning, and continued with short intervals, it generally denoted a fatal termination. The matter ejected from the stomach was various at the beginning, it was only the ordinary contents of the viscus; but after repeated reachings, bile commonly followed. Dr. Russell did not observe any fetid discharges from the stomach; but a blackish liquor sometimes came off in the last stage of the disease. A diarrhœa began sometimes on the first day, but more commonly in the advance of the complaint, and was generally considered as a dangerous symptom; but the stools were less offensive than those in tertian fevers in the same climate. Sometimes dark coloured blood was discharged by stool unmixed with feces, and without griping pains. As a looseness of the bowels was generally detrimental; so, on the other hand, a state

PLAGUE.

of costiveness was attended with no harm or inconvenience.

But the peculiar and characteristic symptoms of the plague, as before stated, are the *buboes* and *carbuncles*, the former being observed in almost all those patients who are not carried off too rapidly to admit of their formation. The carbuncles, however, do not occur in more than one-third of the cases of plague, and very rarely exist alone, being generally conjoined with buboes. Buboes occur in the glands of the groin and arm-pits, and also in the parotid, maxillary, and cervical glands; but those of the groin are most frequently affected.

The inguinal pestilential bubo sometimes appears in the same place as the ordinary venereal tumour, but is commonly situated lower in the thigh. A burning and shooting pain is often felt in the part before any swelling is perceptible by the finger; but when once distinguishable, the gland is always painful on pressure. In the incipient state of the bubo, a small, hard, round tumour is felt under the finger, moveable under the skin, soft, and of its natural colour; but as the swelling increases, it assumes more of an oblong form, becomes less moveable, and the integuments become thickened and tumid. In some cases the swelling is acutely painful, in others obtusely so, and its progress is not less variable. The skin is seldom inflamed in any degree during the first week, though tense and painful; so that in the fatal cases, it generally retains the natural colour; indeed, unequivocal signs of the tendency to suppuration seldom occur till the fever abates, and is manifestly on the decline, as about the eighth or ninth day; the external inflammation then advances, the swelling becomes softer, and breaks between the fifteenth and twenty-second day, when treated simply with poultices. Those buboes which do not terminate in suppuration, usually disperse gradually, and disappear altogether in the second month: some of the inguinal tumours, however, remain hard and indolent for a longer time.

In a very large proportion of those who are attacked by the plague, the buboes begin to appear on the first day of the disease; sometimes they are even the very first symptom of infection; and sometimes they do not arise until the third day, or even later. Sometimes there is a succession of two or three buboes in the same patient.

The *anthrax*, or *carbuncle*, which is not unfrequently conjoined with the bubo, appears under some variety of form. Dr. Russell has described five, Dr. Gotwald (who saw the plague at Dantzic) four, and others three varieties of this pestilential sore. In different instances, it commences in the form of an inflamed pustule, of various size and colour, or of an angry pimple, tubercle, or slightly elevated red or livid spot; and instead of suppurating kindly, it becomes black, and forms a gangrenous eschar, surrounded by an inflamed and tumid margin. The part is affected with a pricking and burning pain. Dr. Bancroft observes, that when carbuncles appear very early, they assume a dark brown or black colour, and remain forty-eight hours or more without being circumscribed by an inflamed margin: they generally indicate the greatest danger. Most commonly, however, they appear only in the advanced stages; and where several occur in the same subject, they generally appear in quick succession. They are seated in different instances, on every external part of the body, even on the *scrotum*, and on the eye-brows; and when they concur with buboes, they usually appear on the same side of the body: sometimes, however, the carbuncles and buboes appear on the opposite sides. Sympathetic buboes occasionally arise in consequence of carbuncles; but they are less intensely

painful than primary buboes, and disperse when the carbuncles suppurate kindly.

Some other eruptive appearances occur during the plague, which are among the symptoms of all malignant fevers: these are especially *petechiæ* and *vibices*, or purple dots and blotches; some of them resembling in size and appearance the marks of flea-bites, and some the stripes and bruises of a whip. In some cases, a sort of marbled appearance of the skin takes place, or the surface is discoloured by narrow streaks of a brown, purplish, red, or livid colour. Most of these appearances, which are obviously of a petechial nature, were vulgarly called *tokens* in the plagues of London; being considered, and not unjustly, as commonly betokening the approach of death. Some of these indeed seem, from the description given by Dr. Hodges, to have been elevated, as if blood had been effused under the cuticle. "The *tokens*," he says, "were of various sizes, sometimes as small as a pin's head, sometimes larger, and as broad as a silver penny. Some were depressed, others prominent. They differed also in their degrees of hardness, some being easily penetrable by a needle or a pen-knife, &c. They were not all of the same colour, but often bore so strong a resemblance to warts, that they were often mistaken for them, not only by the vulgar, but even by the surgeons; and the author himself was sometimes obliged to have recourse to the needle for distinguishing them. A quick sensibility was a good sign, and those which went no farther than the skin would often slough off; whereas when they went deeper, they were deemed dangerous, especially when the part lost its feeling, and threatened sphacelation." (Hodges, *Loimologia*, p. 133.) The same excellent author describes another pestilential eruption; those of this kind were popularly called *blains*, and were a sort of blebs or *bullæ*, containing ichor or serum. These, he says, were "vesications of size from a pea to a nutmeg, encompassed with a variegated circle, generally reddish. They arose with exquisite and shooting pain, and contained an ichor of a yellowish or straw colour, which was so acrid or caustic, that it soon corroded the vesicle, and burst out, of a colour yellowish, livid, or black. These pustules broke out in many parts of the body, their station and number being uncertain; sometimes few, sometimes many: in one case, the whole body was covered all over with them." (Loc. cit. p. 110.) In the directions published by the College of Physicians for the searchers, the latter are ordered to examine "whether there be any blains which may rise in any part of the body in form of a blister, much bigger than the small-pox, of a straw colour or livid colour, which latter is the worse; either of them hath a reddish circuit, something swollen, round about it; which circuit remains after the blister is broken, encompassing the fore." See Certain necessary Directions, by the King's special Command, Lond. 1665.

Such are the symptoms which characterize the formidable malady, the plague. In different cases, they are of course variously combined, and assume various degrees of violence, according to the age, strength, and constitution of the patient. They differ also materially according to the season, and to the particular period of the epidemic; inasmuch that the proportion of fatal cases, among those who are attacked at different periods of its prevalence, varies greatly. But the fatality of the disease is greater in general than that of any other malignant fever, and cuts off the majority of those whom it seizes, from two to seven days from its attack. All ages and conditions, every variety of constitution, strong and feeble, and both sexes under every circumstance, are liable to the infection; which, during those particular seasons in which it has become epidemic, has therefore

PLAGUE.

committed the most dreadful destruction in the population of those towns and districts, which it has unhappily visited.

It may seem extraordinary that the origin of a disease, which has in all ages been the scourge of mankind, should have been always the subject of doubt, or at least of much difference of opinion. It is, however, to this day disputed, whether the plague be propagated by contagion or not; and it must be admitted that there are some difficulties attending either supposition. A similar discussion, indeed, has been carried on, with some acrimony, respecting the epidemics of our own times, especially respecting the yellow fever of the West Indies and America; and some even disputed the nature of the fever, which spread so extensively and fatally among our troops in the recent expedition to Walcheren. The most intelligent writers, however, concur in ascribing epidemic diseases to two sources; namely, to the miasmata or effluvia of marshes, and to contagion, or the exhalations and secreted matter from the bodies of persons diseased. To the former source, marsh effluvia, the intermittent and remittent fevers, which are endemic in particular districts at certain seasons of the year, and often extensively prevalent and fatal, are generally ascribed; and they are distinctly traceable to certain combinations of heat and humidity acting upon vegetable and animal soils. (See EPIDEMIC.) Hence in the autumnal season, flat, marshy countries, the feat of camps and other large congregations of men, and the uncleanly parts of crowded cities, have generally been observed to be productive of intermittent and remittent fevers. (See HEALTH of London.) Now some of these circumstances also concur in favouring the propagation, if not in giving origin to the plague; whence the difficulty of admitting the contagious source of the latter has arisen. It has also been stated, as an objection to the opinion that the plague is propagated by contagion, that, in many places, the disease is seldom entirely absent; yet that it rages epidemically and fatally only at particular times. Thus, it is collected from the bills of mortality of London, that, although there were but four great plague-years in this metropolis during the seventeenth century, namely, the years 1603, 1625, 1636, and 1665, (in the two first of which about 35,000, and in the last 68,000 died,) yet that there were but three years, from the commencement of the bills of mortality in 1603 until 1670, which were entirely free from the plague. In many of these intermediate years, indeed, the mortality of the disease was very considerable: for the bills exhibit 900 deaths by the plague, in 1604; 400, in 1605; 2000, in 1606; the same in the two following years; and even so late as from 1640 to 1648, the number every year exceeded 1000. (See Dr. Heberden's Treatise on the Increase and Decrease of different Diseases, p. 75.) Diemerbroeck remarks, in his excellent Treatise on the Plague, that whenever the plague has been excited out of its proper season, it has not spread; and it has been observed by Dr. Russell, that, in winter time, when infected persons have come to places about Aleppo, some of whom have died of the disease in the families where they lodged, the distemper was not, by such means propagated. Dr. Hodges has also stated, in a strong point of view, the total freedom from infection experienced by those persons, who had fled from London during the ravages of the plague, in the autumn of 1665, when they returned in the winter to the houses and beds in which their friends had died of the malady, without any previous purification having been made of the very linen and clothes which they had used. See his *Loimologia*.

It is likewise an indubitable fact, that the plague has

always first appeared and established its head-quarters in the filthiest parts of crowded, ill-constructed, and large cities, and has committed its most fatal ravages among the lowest of the people. Thus at Grand Cairo and Constantinople it appears almost annually. Blackmore takes notice that the impurity and filth, connected with the galleys and slaves at Marseilles, filled the air with offensive smells, easily perceivable by those that passed along the adjoining shore; and in 1720 the plague broke out there, in a part of the town thronged by the poorest people. In London, Dr. Heberden observes, the plagues of 1626 and 1636 broke out at Whitechapel, a part of the town which abounded with poor and with slaughter-houses: that of 1665 is said to have broken out first at St. Giles's; and there it would probably break out again, if ever we should suffer such another calamity. Hodges affirms, that in 1665 the disease was so much more prevalent among the lower classes, that it acquired the appellation of the *poor's plague*.

All these facts, however, when taken into consideration, along with the more positive evidence in favour of the actual contagion of the plague, perhaps tend only to prove that the human body is more predisposed to be acted upon by the contagion, under certain circumstances, which materially influence the state of the constitution. It must be admitted, indeed, as a matter of daily observation, that a certain predisposition of the body is requisite for the production of all diseases, and for the operation of contagion in particular: otherwise it could not happen that great numbers should escape during the whole reign of an epidemic; that at different seasons of the year, one and the same cause (a chill, for instance, or an act of intemperance) should produce very different diseases, a catarrh, a cholera, or a bilious fever. A particular state of the air is, in fact, absolutely necessary for the propagation of the contagion of the plague; for it is only during a season of moderate heat that it has ever been observed to prevail extensively. In Europe it has invariably raged most violently and fatally in the summer and autumnal months, especially in September. Thus in the plague of London in 1665, the deaths from the plague were, in June, 590; in July, 4129; in August, 20,046; in September, 26,230; in October, 14,373; in November, 3,449; and in December, they were under 1000. (See the Bills of Mortality.) The cold weather of northern climates has invariably been observed to check the ravages of the plague. On the contrary, however, the extreme heat of southern latitudes is equally adverse to the propagation of the contagion; so that the disease is, in fact, unknown in tropical climates. In Egypt and Syria, its progress is always suspended during the hottest months of the year. (See Russell on the Plague, and Bancroft on Yellow Fever, p. 579.) "But a proper state of the air," to use the words of Dr. Heberden, "is not the only circumstance necessary to promote the operation of contagion. During the epidemical constitution, it is highly probable that good diet, and good spirits, and cleanliness, and fresh air, and proper clothing, and exercise, may all contribute to render the body less susceptible of disease; the seeds of which, like those of vegetables, will then only spring up and thrive, when they fall upon a soil convenient for their growth." (On the Increase and Decrease of different Diseases, p. 68.) These observations are corroborated by the fact, universally observed during the prevalence of the plague, that the principal ravages are committed upon the lower classes of the people; and they are perhaps farther confirmed, by the frequent occurrence of pestilence in combination with death and famine, according to the general testimony of historians, during which the people are not only ill-fed, but ill supplied

PLAGUE.

with fuel, clothing, and other healthful accommodations, and also dispirited in the extreme.

Dr. Bancroft has collected some facts and testimonies which concur in pointing out the circumstances which induce a predisposition in the body to receive the contagion of the plague, or to resist its influence. He quotes Dr. Pugno's opinion, that the susceptibility of a person for the contagion is greatly increased by a moderately warm and moist atmosphere; that children, females, and persons of delicate feeble constitutions, are most apt to become infected; and that those who are naturally robust and vigorous seldom take the disease, unless weakened by excessive fatigue, watching, excessive venereal indulgence, or intoxication. Dr. Desgenettes remarks, that the plague seemed more particularly to attack those who are exposed to sudden transitions from a hot to a cold atmosphere, and *vice versa*, such as bakers, cooks, and blacksmiths; and that men addicted to excesses with women and spirituous liquors, very seldom recovered from the disease.

Dr. Bancroft has also adduced some observations, made by himself, in proof of the influence of atmospheric heat and cold, in both their extremes, in rendering the contagion dormant, or in suspending that susceptibility or affinity of the human body, without which it cannot produce disease in ordinary circumstances. Pestilential contagion, he observes, probably exists at all times in Lower Egypt, Syria, and many of the great cities of the Levant, and it is frequent on board Turkish and Greek vessels. When he was in Egypt, he remarked, that the obvious effect of heat in lessening the susceptibilities of individuals, or their aptitudes for taking the disease, was most evident in those who had lately arrived from cold climates, and who were comparatively most affected by the summer's heat; and ascribed his own escape, at that time, to that circumstance. "There were, however, persons in Egypt," he adds, "who had been long accustomed to greater degrees of heat, and who were therefore not rendered insusceptible of the disease, and some few of these caught it after it had become extinct in the British army, and when a person landed from England would not receive it, though he slept in an infected bed; and it was from this cause, that in the autumn of the same year, the disease began at Rosetta nearly two months before the usual time, *i. e.* on the 13th of September, when I first discovered it in two natives of the East Indies, attached to the Indian army; and it was propagated with some rapidity for six or eight weeks, among persons who were either born in, or had just come from, a climate much hotter than Egypt, whilst the British troops directly from England did not receive, and probably could not have been made to take the disease." On Yellow Fever, p. 591.

It is fortunate for mankind, as the same able author has remarked, that the communication of the contagion of the plague depends upon the co-operation of so many favourable circumstances, and particularly upon that of a suitable temperature, and of certain aptitudes and susceptibilities in the human subject; for without such requisites, or such obstacles to its propagation, the earth might have long since become desolate.

It would seem superfluous to enter into a long detail of facts to prove that the plague is a contagious disease, notwithstanding the refusal of some persons to admit the fact. The majority of the histories of the plague teem with evidences from which it is undeniably inferred. It is more especially to be inferred, however, from the circumstance of the multitude of medical attendants on the sick under this malady who have perished by its attacks, and parti-

cularly of those who have been under the necessity of the most close contact with the infected. Dr. Samoilowitz, who for many years officiated as an army surgeon in places where he had numerous opportunities of seeing persons under the plague, and especially during that of Moscow in 1771, has filled nearly one hundred pages of his treatise "sur la peste," with proofs of its contagious influence; and among these he mentions, that having successively volunteered his services as chief surgeon, in three of the principal hospitals of Moscow, all the assistant surgeons who were employed under him, fifteen in number, took the disease, which terminated fatally in eleven of them. The medical officers of the French army, during their campaign in Egypt, experienced the effects of the contagion to a great extent; about eighty of them perished by the plague within one year, according to Dr. Sotira, who was one of the survivors. He adds, that in the two following years, it was thought expedient to employ Turkish barbers to dress buboes, carbuncles, and blisters, as well as to bleed, and apply frictions of oil, under the inspection of French physicians and surgeons, and that, in consequence of this arrangement, only twelve medical officers died in twice the former time. He also states, that more than half of the Turks, who were thus employed to assist the French surgeons, took the plague, which, in several instances, proved mortal; though among a considerable number of other Turks, employed at Rosetta by the French to bury the dead, only one caught the disease. This is one of the many facts which indicate that there is comparatively little danger in handling the bodies of infected persons after death, than while alive. See Bancroft, *loc. cit.* and Gaetan Sotira, *Mem. sur la Peste, observée en Egypt, p. 5.*

The plague, which ravaged Marseilles in 1720, appears to have afforded ample evidence of its contagious nature. The report transmitted to the regent by M. Chicoineau on the 18th of August, represents the physicians and surgeons as unanimous in their declaration, "that when one person in a family was attacked and died, the rest soon underwent the same fate, inasmuch that there were instances of families entirely destroyed in that manner; and if any one of an infected family fled to another house, the contagion accompanied him, and proved fatal to the family where he had taken refuge." (*Relation Historique, p. 115.*) It appears, too, from the historical record just quoted, that the first hospital opened for the infected proved fatal to all the attendants. The introduction of the plague into the Hôtel Dieu was traced to a woman received as a patient from the rue de l'Escale, the street in which the distemper first broke out. Two of the nurses who assisted at her reception, and the matron who changed her linen, were taken ill the next day, and died after a few hours' illness. In consequence of the dreadful rapidity with which the contagion spread in that establishment, it destroyed physicians, surgeons, apothecaries, confessors, and all the other officers and servants, with the whole of the poor in the hospital, including above three hundred foundlings. The priests and monks who attended the infected suffered in the same manner as the medical assistants. And, lastly, of two hundred and thirty galley-slaves, employed in going into the infected houses, and burying the dead, two hundred and twenty perished in the space of ten or twelve days. The whole tenour of the history of that plague, indeed, concurs to establish the fact of its contagious nature. We shall, therefore, conclude this brief detail with the observations of Dr. Russell, suggested by his experience in the East.

"If of one hundred persons, exposed to the infection

of the plague by a near approach to the sick, ninety should fall ill, shall human inability to assign satisfactory reasons for the preservation of the other ten, be converted into a positive argument against the disease having been caught by contagion? If persons retired from all commerce with the infected and their attendants, breathing the same air with the rest of the inhabitants, and nourished by the same aliment, remain untouched during the ravage of the plague, as long as they continue secluded, but upon unguarded communication are taken ill like others,—can any rational doubt arise about the cause of their former security? Or if through stealth, or neglect of requisite precautions, substances tainted by the sick should be conveyed into these secluded retreats; and persons living temperately as before, ignorant of what had happened, and consequently in the midst of imaginary security, happen to be seized with the distemper,—can it with any show of reason be ascribed, not to contagion, but to terror, or to colluvies in the stomach and bowels, produced by intemperance and bad aliment? The instances here alluded to are not the creation of fancy, but strictly consonant to repeated experience in Turkey; to say nothing at present of what has been observed at Marseilles, and in various cities in Europe." Russell on the Plague, p. 208.

We cannot, therefore, but consider the *contagious* nature of the plague as satisfactorily proved, though not demonstrable. The principal difficulty in the way of an unqualified admission of the proposition, is the complete and often speedy eradication of the disease in a place, where no particular means of purification have been employed, by which the contagion might be removed or destroyed. But this difficulty is not insurmountable, as we have already attempted to shew, and as might be farther illustrated by a reference to the progress of those contagious diseases, which admit of no dispute, such as the small-pox and measles. For even these are only widely epidemic and feverishly fatal at particular seasons, when circumstances, that are not always cognizable, give a peculiar virulence to the contagion, or a predisposition to the human constitution to receive its influence.

The contagion of the plague, like that of the common malignant fever, or typhus, of temperate climates, and unlike that of small-pox, may infect a person a second time. Dr. Bancroft says, "two cases of *re-infection*, or second attacks of plague, fell under my observation in Egypt; one occurred in Mr. Webster, then an assistant surgeon, and the other in a soldier of the 27th regiment, each of whom had a bubo: they were, however, but slightly indisposed, the weather having become hot. Dr. Buchan had a second attack, but with only a small carbuncle, as he informed me. Dr. Price also had a second attack, without either bubo or carbuncle, but, according to his account, with a violent affection of the head and nervous system." In general," he adds, "I think second attacks are milder than the first, though Dr. Price informed me of his having seen a lad, who, under such an attack, died on the second day. Pugnet says, that re-infections, when they occurred, were oftenest in persons who had been mildly treated by the first attack; and that several of these had the disease very violently the second time, immediately after using the bed or blanket of persons who had died of it." (Loc. cit. p. 599.) The fact of the occurrence of the plague in the same individual more than once, is, indeed, fully established upon the best authorities, although some have disputed it. Merceus says of the plague at Moscow, "Experientia comprobatum sit, hanc (pestem) illos non solum in variis vitæ periodis, sed et eadem epidemia, bis, aut sæpius occu-

pare posse." (Obs. Med. p. 123.) Dr. Russell also bears testimony to the same fact in the epidemics which he witnessed at Aleppo. Nevertheless, a second infection is admitted to be rather a rare occurrence, at least during the same epidemic. In above one hundred and twenty pestilential cases recorded by Diemerbroeck, there are only two in which the patients had been infected twice during the same season; but he had met with several instances of persons attacked at Nimeguen, who had suffered the plague some years before. (See Diemerbroeck De Peste, lib. iv. Hist. 37, and 45.) Whether the observation of Thucydides is thus sanctioned, as applicable to the true plague, may be questioned. He says that, in the plague of Athens, "those who recovered had much compassion on those who were dying, and those who lay sick, as having known the misery themselves, and were now in a secure condition, for it never seized the same person twice so as to be fatal." (Thucyd. de Bello Pelopon. lib. ii.) As the symptoms described by Thucydides were more analogous to those of the small-pox than of the true plague, as above stated; so this confidence of the convalescents in their security (which is not usual in cases of the true plague when epidemic) rather confirms the opinion the plague of Athens was small-pox.

With respect to the *treatment of the plague*, very little that is satisfactory can be collected from the writings of those who have witnessed its ravages. Dr. Bancroft expresses an opinion, that, until we know more of the ways and means by which nature endeavours to overcome it, we can perhaps do but little for her assistance, except by restraining all violent and dangerous symptoms, all excessive and debilitating evacuations, and supporting, when necessary, the powers of life, by a moderate use of wine, ether, opium, volatile alkali, and Peruvian bark. "The instances of persons who have strangely recovered from the plague, after having wandered alone about the country, particularly in Egypt, exposed to cold and wet, seem to indicate, that even the most moderate sweating is at best useless; but on the other hand, the unsuccessful trials made by Dr. Price, of the cold bath, afford no encouragement to repeat such applications to the surface. In some few cases, where the disease occurs in the vigorous and robust, and is accompanied with highly inflammatory symptoms, bleeding might perhaps prove beneficial, if employed within a few hours from the attack; though in general very bad effects appear to have resulted from this evacuation. Mild emetics are said, in some cases, to have proved beneficial, given at the very beginning of the disease."

This paragraph seems to contain the sum of the information, which is to be found in the records of modern medicine on the subject. *Blood-letting*, in general, is to be deprecated in a disease, in which the inflammatory symptoms are seldom considerable, and the depression of strength usually great and sudden. And in like manner, all violent evacuations, either by *emetics* or *purgatives*, appear to be detrimental, especially as violent vomiting and diarrhoea are apt to occur spontaneously, and are deemed very unfavourable symptoms. Dr. Russell remarks, that "the neglect of purging at the beginning was not followed by the consequences which might rationally have been expected," and, he adds, "I never saw any acute distemper, where costiveness was attended with so little inconvenience. Nevertheless, I think it rational, by gentle means, to clear the bowels at the beginning from any colluvies that might happen to be lodged there; for though that did not constantly prevent looseness, or other symptoms produced by matter pent up, and rendered more putrescent by the fever, yet I think it sometimes had that effect; and the passage of the bowels often appeared

PLAGUE.

peared to relieve the head, both in the augment and decline of the disease."

It appears to have been a very early and general opinion, as Dr. Bancroft remarks, among the physicians of this and other neighbouring countries, that those who were attacked with the plague, and other contagious diseases, had imbibed a *morbid poison*, and that it was necessary, above all things, to assist nature in expelling that poison from the body, and this principally by *sweating*, which Morton called the king's highway. In "certain rules, directions, or advertisements, for this time of pestilential contagion, first published for the behoofe of the city of London, in the visitation of 1603," and republished upon the recurrence of the plague in 1625, *copious sweatings* were directed to be excited by strong sudorifics, with warm beds and bed-clothes, "so soon as any of them (the poorer sort of people) apprehend themselves to be taken with the plague," and these were to be repeated every eight hours, and they were to "continue this course for four or five days;" and while they were sweating, it was ordered that they were not to be suffered "to rest or sleep." The same modes of treatment were adopted in the "advice set downe by the College of Physicians, by his majesties special command," which was printed in 1630. Not only strong sudorifics were enjoined, but it was directed "that there be good fires kept in and about the *visited houses*, and their neighbours," and "to make fires rather in panes, to remove about the chambers, than in chimneys, the better to correct the ayre of the houses." In 1665, the College of Physicians were required by government to inspect the rules of former times, and make such alterations as they deemed proper; and among the directions which they then published, after mentioning bleeding, purging, and vomiting, they say "these three great remedies rarely have place in the plague, but are generally dangerous, and most of all purging, by any strong medicines," but express an opinion, that "the poison is best expelled by sweating, provoked by *posset-ale*, and *London treacle*" mixed; and order the patient to "be put to bed to sweat, well covered in a blanket, without his shirt, for twenty-four hours, every fifth hour renewing his cordial, but in half the quantity, between whiles refreshing him with posset drink, oatmeal caudle, or thin broths, made jelly wine, or hartshorn jelly;" and, if necessary, warm bricks, wetted with vinegar, and wrapped in flannel, were to be put to his feet, and care was to be taken, that he "sleep not till the sweat be over." *Blisters* were at the same time to be applied "behind the ears, about the wrists, near the arm-pits, on the insides of the thighs, and near the groin, to draw forth the venom. The buboes were to be "always drawn forth, and ripened, and broke with all speed."

Such was the universal practice employed in the plagues of the seventeenth century; and it is enough to have stated it to prove the mischievous consequences which it must have produced, to the satisfaction of every pathologist of the present day. The miliary fevers, of which the writers of those times speak so much, were the actual product of this violent excitement (see MILIARIA); and the small-pox was rendered doubly fatal by the same treatment. That coolness of the bed and apartment, with the most liberal admission of air, and the most complete rest that can be obtained, should be enforced under every form of fever, is now demonstrated beyond the possibility of dispute. And it is not less clearly ascertained, with respect to the management of the buboes, or glandular swellings, that, although it may be proper to promote their suppuration by emollient cataplasms, &c., where a natural disposition to that issue is evident; yet that there can be no danger or impropriety in

favouring their dispersion or resolution, by the usual means, when a spontaneous tendency to such a termination is observed. Dr. Bancroft justly says, "I know that the sudden retrocession of buboes, previous to suppuration, and whilst other symptoms indicating danger subsist unabated, is often followed by death. But this mortality is not in such cases produced by any change in the bubo itself, or by the retention of any matter which ought to be discharged, but by such an extreme diminution of the living power, or other injurious effects of the disease, as is incompatible with the continuation of a suppurating process, and also with the patient's recovery; and, therefore, this retrocession is to be considered not as the cause of death, but as an indication and consequence of that condition of the patient, from which death necessarily resulted; and on the other hand, when these glandular swellings rise, and suppurate favourably, they indicate such a state of the living power and of the system, as is likely to overcome the disease, without the supposed benefit of an evacuation of morbid poison by that suppuration. The same reasoning appears applicable to carbuncles, though in their gangrenous state, and when not surrounded by concentric inflamed rings, they require hot stimulant applications, and afterwards such as will promote a suppuration, and a separation of the carbonaceous crust." On Yellow Fever, &c. p. 617.

It may be added, that *mercurial* preparations were employed, and pushed as far as they could be carried, during the plague at Marseilles (according to M. Deidier) without any good effect. Orræus, Pugnet, and Sotira, likewise give their testimony to the same result of their own experience, even when carried to salivation. But where the disease is violent, it is obvious that sufficient time cannot be given to affect the salivary glands, even if the advantage of doing so were clear; and when they have been affected, it is probable that this was rather the effect, than the cause, of the mild and protracted state of the disease.

Frictions with oil were strongly recommended by Mr. Baldwin for the cure of the plague; but the evidence in favour of their efficacy is very defective. These frictions, Dr. Bancroft informs us, were tried extensively by the French physicians in Egypt, and with very little, if any benefit, though in a few cases they seemed to give temporary ease. Pugnet indeed says, that they were not only useless, but caused anxiety and disturbance to the sick; that of fifteen patients to whom these frictions were applied, under the French physician Carrié, one recovered with difficulty, and all the rest died; and that where they seemed to do good, the disease was always mild. With so much reason to doubt of their efficacy, there is a strong objection to their use, arising from the very great danger of communicating the disease to the unfortunate person by whose hands they may be applied, and thus destroying many lives, without much probability of saving one. Bancroft, p. 623.

Prevention of the Plague.—The measures to be adopted for the prevention of the propagation of the plague are directed to two objects; namely, to the prevention of the introduction of the contagion into any town or country from those places where it prevails; and to the prevention of its propagation among the population, if it have already been introduced.

It seems to be generally admitted, that the plague does not originate in this country; and, therefore, from its insular situation, the infection can only be introduced through the medium of ships. Egypt, the Levant, and other parts of the Mediterranean, are seldom entirely free from the malady in the cool and temperate seasons; and probably, therefore, never free from the lurking contagion which the congenial

PLAGUE.

congenial temperature annually brings into action. It is chiefly, therefore, through the medium of the commerce of the Mediterranean, that the importation of the contagion is to be apprehended; and to guard against this danger, the system of *quarantine* is adopted by the government of this country. It will not be necessary here to enter into a full detail of this system in all its parts, as it will be described under its proper head. (See *QUARANTINE*.) The objects of the system are, in the first place, to detain the individuals who may possibly have the infection lurking about them, a sufficient length of time from any communication with the people on shore, in order to ascertain whether the disease shall make its appearance in them; but, in the next place, to perform a still more important service, by subjecting all goods, clothes, and merchandize, which may retain infection, to a process of purification. It is well known, not only from numerous facts recorded in the history of almost all modern plagues, but from the testimony of the most experienced physicians in respect to malignant fevers in general, that these *fomites*, as they are called, or substances imbued with the contagion from the bodies of the sick, may retain their infectious quality an indefinite length of time, and do in fact more readily communicate the disease, than the persons of the infected. In addition, therefore, to the mere delay of the quarantine, the purification of the goods contained in the ships makes a principal part of that system; and it is chiefly accomplished by the establishment of lazarettoes and pest-houses, at the principal ports to which vessels from the Mediterranean usually come. The persons, if any prove to have been infected, and shew symptoms of the plague, are immediately removed to these houses, and separated from the healthy; and the goods are there also opened out, and exposed to the air, and fumigated with sulphureous vapours, and those of the mineral acids. (See *FUMIGATION*.) The most rigid adherence to the principle of separation, established by the quarantine laws, is enforced by the statutes, and the system appears to have answered the purpose of preventing the importation of pestilential contagion, since it has been fully practised.

If, however, these measures should fail to prevent the introduction of the plague into any large town, it then becomes expedient to devise the best means of preventing the spreading of the contagion among the people. This, indeed, is an object of difficult attainment. The first rise and appearance of the plague is not always recognized, and therefore it has often made considerable progress before any public measures are called for. The great rule of resisting in the beginning ("princiipiis obsta") is of peculiar importance in such a case; and it is much to be lamented, as Dr. Mead has remarked, that, in addition to this physical difficulty in the execution of the rule, the very steps which have commonly been taken by the police, with the view of arresting the contagion, have unfortunately had a direct tendency to impede the operation of this maxim, and to accelerate the progress of the epidemic. Dr. Mead justly states, that the directions of the magistrate, under such circumstances, ought to be such as to encourage the families first infected to make their misfortune known, for the sake of obtaining assistance, as much as if their house were on fire; whereas the measures usually adopted on these occasions have, in fact, been themselves a severe punishment, and must have contributed to make the infected conceal the disease as long as possible.

When the plague first shewed itself in London in 1665, the orders issued by the lord mayor and aldermen, and sanctioned by the College of Physicians, principally related to the strict imprisonment of the sick in their own houses, by

watchmen attending night and day at the doors to prevent communication; and this was to continue at least a month after all the family was dead or recovered. Each infected house was ordered "to be marked with a red cross of a foot long, in the middle of the door, evident to be seen, and with these usual printed words, that is to say, *Lord have mercy upon us*, to be set close over the same cross, there to continue until lawful opening of the same house." (See *Orders by the Lord Mayor and Aldermen, concerning the Infection of the Plague, 1665*.) Independently of the misery thus suffered by the families shut up, when comfort and assistance from friends is most required, and strangers to every thing but the melancholy view of the progress which death makes among themselves, the inefficacy of the plan to prevent the spread of contagion is obvious. The contagion must be accumulated and rendered more virulent by such confinement; "the shutting up houses in this manner," as Dr. Mead observes, "is only keeping so many seminaries of contagion, sooner or later to be dispersed abroad; for the waiting a month or longer from the death of the last patient, will avail no more than keeping a bale of infected goods unpacked; the poison will fly out, whenever the Pandora's box is opened." (Mead on the Plague, p. ii. chap. 2.) This plan, too, excited the universal apprehensions of the people, lest they should be shut up, which, probably, like all other impressions of fear, increased their liability to the infection. It occasioned the concealment of the disease as long as possible, which necessarily contributed to give it vigour, and to spread it; nor was it possible to maintain it rigidly; for many broke out of their confinement, by getting out at the windows, &c. or by bribing the watchmen at their doors, and sometimes by assaulting them; and thus contributed to propagate the contagion. On the other hand, there are some strong proofs recorded in the plagues of London in 1625 and 1636, of the diminution of the mortality which occurred after the sick houses were permitted to be open. See Mead, loc. cit.

On the actual occurrence, or on the apprehension of the occurrence, of the plague in any place, a council of health should immediately be appointed, consisting of some of the principal officers of state, some of the magistrates, and two or three physicians, &c.; and this council should be entrusted with such powers, as might enable them to enforce the execution of their orders with impartial justice, avoiding all unnecessary hardships. Instead of ignorant old women, who have generally been appointed *searchers* in parishes to examine the causes of death, that office should be committed to intelligent and active men, whose business it should be to report to the council of health the first occurrence of extraordinary deaths in any district, so that the suspected bodies should be examined by skilful physicians. The plague having almost invariably appeared among the poor in the outset, the measures to be adopted are principally applicable to that class of people. If, upon the report of the examiners and physicians, the plague is actually ascertained to have occurred, the families should be immediately removed, the sick and the found to different receptacles out of town, in which every care should be taken to purify the clothes and persons of both, on admission. The wealthy might be compelled to remove to their country houses, following a similar plan of separation and purification. From what is now known respecting the nature of contagion, it is certain that if these lazarettoes were kept in a cleanly and well-ventilated state, like the houses of recovery for typhus, there would be much less danger in giving attendance upon the sick, and the chance of recovery would be much augmented. It is well ascertained by experiment; that contagion is very much weakened

weakened in its virulence by dilution with fresh air, and that, in this diluted state, it may be breathed for a certain time with impunity. . See CONTAGION, and HOUSE of Recovery.

There are many examples of the success with which these plans of early separation of the infected have been pursued. The magistrates of the city of Ferrara, in the year 1630, when all the surrounding country was infected with the plague, observing the ill consequences which every where ensued from endeavours to conceal the disease, by keeping the sick in their houses, resolved, whenever the occasion should occur, to adopt a different method. Accordingly as soon as they were informed that a person had died of the plague in their city, they immediately removed the whole family to which he belonged into a lazaretto, where they all, seven in number, died. But though the disease was thus malignant, it went no farther, being suppressed at once by this method. Within the space of a year, the same circumstance recurred seven or eight times, and the same proceeding put a stop to its progress. The example of this city was afterwards followed more than once in some other towns in the same territory, and with such complete success, that it was thought expedient, for the common good, to publish in the Memoirs of the people of Ferrara this declaration; "that the only remedy against the plague is to make the most early discovery of its occurrence that is possible, and thus to extinguish it in the very beginning." A very similar success was obtained by cardinal Gastaldi at Rome, in the plague of 1657. Being appointed commissary-general of health, with full powers, by the pope, he ordered all infected persons to be removed upon the first notice, to a lazaretto in the island of the Tiber, and all who lived in the same house with them, to other hospitals just without the city, in order to be sent to the island if they should fall sick. In two months he thus cleared the city of the plague, which had continued in it nearly two years; and it was particularly observed that, although previously, when the disease once got into a house, it seldom ceased without seizing the whole family, yet, under this management, scarcely five out of a hundred of the found persons, thus removed, were infected. See Gastaldi, de avertenda Peste, cap. 10.

When the sick families are removed, their goods should be destroyed, or buried, and the walls and floors scoured, lime-washed, fumigated, and well aired. The streets and alleys should be cleaned with peculiar care, and washed daily if possible. It has generally been deemed advisable, too, to take up all beggars and vagrants who have no fixed residence, and may become a great cause for disseminating the contagion; and to prohibit all public amusements and assemblies of people, by which the disease might be communicated, through the promiscuous intercourse of such meetings.

Upon the supposition, (which is doubtless erroneous,) that the atmosphere is impregnated with contagion, or with some impurities which favour its propagation, the purification of the air has been an object of solicitude at all times, and fire has been recommended both by the ancients and moderns for this purpose. This opinion, however, seems to rest upon no better foundation, than a tradition that Hippocrates put a stop to a plague in Greece by kindling large fires; a circumstance which is nowhere mentioned in his works. It appears, indeed, that in after times these fires were made with juniper, cypress, resin, myrrh, and other aromatic weeds and gums, and that a sort of fumigation, and not the mere heat of fires, was the object of the practice. The experiment, when made in London, during the last plague, does not lead to any favourable inference respect-

ing the operation of this practice; for Dr. Hodges has stated, that fires having been ordered in all the streets for three days together, there died in one night immediately following no less than four thousand persons; whereas in any single week before or after twice that number had never been carried off. (Loimologia, p. 24.) The same observation appears to be applicable to the firing of guns, which would likewise be productive of the additional evil of exciting constant alarm, and disturbing the sick.

It is certainly desirable that the population should be thinned as much as possible, at the first appearance of the plague, by the departure of as many people from the town into the country as can conveniently do so. Those who are under the necessity of remaining, should adopt as far as possible a system of seclusion; for, however improper it may be to shut in the contagion, where it has already appeared, it must obviously be prudent to *shut it out*. Hence many persons have effectually preserved themselves and their families, in those countries where the plague often prevails, by shutting themselves up, and avoiding all unnecessary communication with the public, before any of them had received the infection. In large houses, in which a full ventilation could be accomplished, the chance of escape under this system of exclusion would be great; and even if any person should be taken suddenly ill, an immediate separation from the rest of the family would probably preserve them from the contagion. Dr. Russell, during the plague at Aleppo, shut himself up in his house, and prescribed to numerous patients who were brought to his window, which was a few feet above the ground, and by this plan escaped the infection entirely.

In houses in which the disease has already appeared, cleanliness and a free admission of air are the best preservatives; indeed, the circumstance of the comparative rarity of the diseases among the higher classes of society can only be explained upon this principle. Constant washing or mopping the apartments of the sick also contribute materially, by the coolness produced, to benefit the sick. The fumigations with aromatic herbs and gums, employed on those occasions, are not of any effectual use, and the very odours which they emit, rather conceal the presence of offensive vapours, than contribute to destroy them. The fumigations with the mineral acid vapours, obtained by decomposing nitre or common sea-salt, are, however, possessed of the power of destroying contagion. (See FUMIGATION.) The same fumigations, therefore, should be applied to the linen, beds, furniture, &c., in preference to the mere smoking, or the use of aromatic fumes, which were recommended previously to the discovery of these more efficient methods. See an ample account of the ancient modes of fumigation in Dr. Russell's Treatise on the Plague, book vi. ch. 6. p. 561—8.

The next means of prevention to be considered, are those by which individuals may defend their persons against the prevalent contagion. These, however, lie within a much smaller compass than the public appear to suppose. There is certainly no direct antidote against the infection, which can be externally worn, or internally taken. It were superfluous to describe the ingredients of the little bags, balls, ointments, and amulets, employed as preventives of the disease; as they have no claims whatever to the title of antidotes, and are, for the most part, either the offspring of empirical craft, or mere innocent devices, to give confidence to those who are under the necessity of approaching the sick. In this last view, indeed, such as do no harm may be admitted, in compliance with popular notions; but where such reliance is placed in them as to remove more important caution, even these are to be deprecated.

As to the alleged internal preservatives, with which the older medical books are copiously stored, they are in general composed of a complex farrago of herbs and gums, of very questionable properties of any kind. These have been copied, with very little alteration, from the formulæ of dark and ignorant times, and consist of a few medicated ales, distilled waters, and electuaries. It will be sufficient to mention one of these compositions, calculated for the rich, which was preserved among the revised directions of the College of Physicians in 1665, and was disgraced by the following ingredients; oriental bezoar, pearl, hyacinth stone, unicorn's horn, and lignum aloes, the proportion of the last article being about three grains to four hundred and fifty of the other ingredients. In truth, unless individuals have a strong prepossession in favour of these useless expedients, and lose all confidence without them, they may be fully dispensed with. The principal system of prevention that can be of any avail, must consist in maintaining that state of health in which we are least liable to suffer from the exciting causes of disease. We must neither weaken the body by evacuations, nor stimulate and excite plethora by high living. A temperate and regular course of life, and a temperate use of customary liquors, promise every advantage that can be expected from cordial and stomachic medicines; inanition, long fasting, immoderate watching, late hours, heated rooms, casual debauches, excessive fatigues, sudden changes in diet, should be cautiously avoided; inasmuch as whatever destroys the balance of moderate health, induces a predisposition to disease, under which contagion, like other occasional causes of disorder, more readily operates upon the system. Grief, terror, despondence, and other debilitating affections of the mind, have been universally held to be of most dangerous tendency in pestilential times; while, on the contrary, a regular flow of spirits, cheerfulness, a temper not given to anticipate evils, and a lively hope of escaping infection, are considered as the best safeguards against contagion. These, however, it is not in the power of medicine altogether to bestow; but this consideration affords the only apology for the use of the inert amulets before mentioned. The use of tobacco was considered by Diemerbroeck and others as conducive to repel the infection of the plague. But the experience of Dr. Russell led him to doubt the correctness of this opinion; as those who used tobacco copiously did not appear to be less liable to the disease than others. At Aleppo, indeed, the custom of smoking is universal both among men and women of all ranks, and therefore the very fact of the frequent prevalence of the plague seems to afford a refutation of this opinion. The best preservative is certainly to avoid a near approach to the sick, and especially to avoid the contact of the sick and of their clothes. The remarkable fact, mentioned by Dr. Samoilowitz, that all the assistant surgeons in the hospitals at Moscow, took the plague, while the physicians, who only walked among the sick, but carefully avoided contact, generally escaped, affords a strong proof of the greater facility with which actual contact communicates the infection.

Moral Consequences of the Plague.—Having stated every thing which appears to be material in the physical history of the plague, we cannot altogether omit the consideration of some of the moral evils, which have commonly been observed in the train of every severe pestilence. So urgent are the physical distresses which pestilence inflicts, and universal the interruption to the ordinary intercourse of social life which it occasions; so necessary is it for individual safety to shun all communication with others, and so difficult, therefore, to obtain assistance when in need of it;

that a system of selfish principles becomes every where prevalent, and the ordinary moral rules of conduct are every where laid aside; and vices, follies, and crimes, of every description, contribute to augment the sum of misery, which pestilence brings with it. The extreme uncertainty of the tenure of life, when every day may probably terminate it, seems to loosen the moral ties of the people, partly because multitudes of those who are the arbiters of individual character are destroyed, partly because, in the general confusion, the chance of escaping detection is much diminished, and partly because the probability of living to undergo punishment is exceedingly small. The extreme and sudden changes of fortune, too, which the death of whole families brings unexpectedly to many, unhinges the moral feelings, and leaves the indulgence of the passions to be pursued with little controul.

A striking picture of the dissolution of morals, during the prevalence of the pestilence at Athens, has been drawn by Thucydides. After stating that, in consequence of the dreadful mortality, the people, not knowing what to do, or whither to go, began to neglect all their duties sacred and profane, he first observes, that the rites of burial were not performed at all, from the destruction of servants and domestics, or performed in the most irregular manner. Some, he says, would take possession of the funeral piles erected by others, and anticipating their arrival, would lay the bodies of their friends upon them, and set them on fire; while others would deposit their corpse upon the burning pile containing one already partly consumed, and retire. "But this malady," he proceeds, "was the source of much greater depravities to the city in other respects. For people now dared to do many things openly, which they were heretofore compelled by shame to conceal; and they calculated upon their sudden change of fortune, seeing that many of the wealthy perished, while those who formerly were destitute, became rich with their property. They, therefore, deemed it right to set about the immediate enjoyment of it, and gave up all mind to pleasures, considering that they in turn might be deprived of the treasures, and of life itself in a few days. Nor was any individual disposed to undertake any labours for an honourable reward, because he thought it uncertain whether he should not die before he could obtain it. Whatever each person deemed agreeable or lucrative to himself, this he considered as expedient and honourable; and he did not allow himself to be restrained in the pursuit of it, either by the fear of God or of human laws. This indifference to all moral and religious duties, arose partly from the circumstance, that the fulfilment or neglect of them appeared to be equally unavailing; for all equally perished; and partly from the general expectation that no one would survive a sufficient length of time to undergo trial and punishment. And many persons, considering themselves already doomed by fate to worse punishment than the laws could inflict, determined to enjoy some of the pleasures of life before the time of suffering arrived." Thucydides, lib. ii. § 53.

Very similar accounts of the dissolute state of the public character, attendant on times of pestilence, are related by other writers, who have witnessed these calamities. In the interesting description of the plague at Florence in the year 1348, given by Boccaccio in the introduction to his Decamerone, many allusions are made to this lawless condition of the city. After describing the different views which some persons adopted as to the mode of self preservation; he says, "others maintained free living to be a better preservative, and would baulk no passion or appetite they wished to gratify, drinking and reveling incessantly from tavern to tavern,

PLAGUE.

tavern, or in private houses, which were frequently found deserted by the owners, and therefore common to every one; yet avoiding, with all this irregularity, to come near the infected. And such at that time was the public distress, that the laws human and divine were no longer regarded; for the officers to put them in force being either dead, sick, or in want of persons to assist them, every one did just as he pleased." Again, he says, "I pass over the little regard that citizens or relations shewed to each other; for their terror was such, that a brother even fled from his brother, a wife from her husband, and, what is more uncommon, a parent from its own child." From the desertion of friends, and the scarcity of servants, who required enormous wages, multitudes died who might have been saved, and from mere necessity, he observes, many customs were introduced, different from what had before been known in the city. And he adds, it fared no better with the adjacent country; for, to omit the different castles about us, which presented the same view, in miniature, with the city, you might see the poor distressed labourers, with their families, without either the interference of physicians or help of servants, languishing on the highways, in the fields, and in their own houses, and dying rather like cattle than human creatures; and growing dissolute in their manners like the citizens, and careles of every thing, as supposing every day to be their last, their thoughts were not so much employed how to improve, as to make use of their substance for their present support, &c."

But while the dread of contagion and death have thus contributed to annihilate the best feelings of human nature, and to cut asunder all the moral ties of society, during the prevalence of pestilence; other passions of a selfish kind were also called into action, which overcame this fear, and actually led the people to rush into the presence of contagion, and thus to multiply the victims to its fatal malignity. Avarice was one of these misleading propensities. M. Bertrand, when describing the effects of the plague at Marseilles in 1720, remarks that "the avidity to take possession of an unexpected inheritance was also to many the fatal cause of their own destruction. Called to the entire succession of the wealth of a whole family, to whom perhaps they were very distantly related, and impatient to know the extent of their new acquisitions, they entered, without precaution, into infected houses, and searching indiscriminately among the effects of the deceased, they often found what they sought not, and paid with their lives the forfeit of their cupidity. Their fatal heritage then devolved to relations yet more remote, fortunate if they could profit by such an example, and not fall equally martyrs to indecent and unreasonable transports. It was not, however, always the legitimate heirs on whom the punishment of their avidity fell; it was often those who found in the effects they stole the just forfeit of their crime. In vain had the commandant absolutely prohibited the removal of any clothes or effects from one house to another; a blind and headstrong rapacity despised alike these wise ordonnances and the perils of the contagion." See Bertrand's Historical Relation of the Plague at Marseilles, translated by Miss Plumtre, chap. xix.

Avarice, however, was not the only passion which was excited in this extraordinary degree, and contributed to extend the infection. "Another abuse of a very singular nature," says M. Bertrand, "occasioned more than all this partial renewal of the malady. Will it be believed? scarcely had the contagion begun somewhat to diminish in its ravages, when the people, impatient to repair the mortality it had occasioned, thought of nothing but re-peopling the city by new marriages; like mariners who have been in im-

minent peril of shipwreck, but are no sooner arrived in port, than, forgetting the danger they have escaped, they seek, in new pleasures, to drown the recollection of past troubles. Our temples, long shut up, were now only opened for the administration of this sacrament. A species of phrensy seemed to have seized on both sexes, which led them to conclude the affair, of all others the most important in the world, in the space of twenty-four hours, and to consummate it almost at the same instant. Widows, whose cheeks were yet moist with the tears they had shed over a dead husband; consoled themselves in the arms of a living one, who perhaps was in like manner snatched from them a few days after, and in a few days more they were wedded to a third." Some of the physicians imagined that this frantic passion was a consequence of the malady; but M. Bertrand explains it more plausibly upon the great change of circumstances which many had undergone; he might also have added, the extreme uncertainty of the tenure of life, and the consequent determination to make the most of its pleasures, which has been noticed above. The numerous marriages, however, thus hastily concluded, were the occasion of spreading afresh the fatal infection; so that the bishop determined that no marriage should be licensed, unless the parties demanding it could produce certificates of health from the physicians, and as the sickness abated, it became their principal occupation to receive the disagreeable visits of those who were frantic to rush into the bonds of marriage.

But these were not the only moral evils attending the pestilence, for every species of crime aggravated the sufferings of the unfortunate city. "If the people had shewn no other signs of having forgotten their past misfortunes, than the joy which these new marriages occasioned, there would have been no reason," says M. Bertrand, "to fear that a ceremony, honoured by the first miracle of our Saviour, authorised by the laws, and necessary to society, would irritate the Lord anew against us, provided all was conducted in conformity with Christian decency and rectitude. But what was likely to draw down upon us much greater judgments from his anger, were the thefts, the plunderings, and an infinity of other crimes, the horrors of which we dare not here retrace. For these their perpetrators promised themselves impunity on the part of men from the troubles of the contagion, and absolution on the part of heaven, by the favour it had shewn them, either in their having escaped the disease entirely, or recovered from it, when it proved mortal to so many thousands of their fellow-citizens. While the arm of the Lord was yet extended over us, a general licence was seen to reign among the people, a depravity of morals frightful to think on. Some seized on houses left vacant by the mortality; others forced open those that were shut up, or guarded by persons incapable of resistance. They entered those where, perhaps, there remained only one person languishing with the malady, forced open the closets and drawers, and took away whatever they found most precious, often carrying their infamy to the length of delivering themselves from an importunate witness, who had otherwise but a few moments to live. These enormous crimes, much more frequent in the height of the malady than in its decline, were generally committed either by those who served the sick, who carried away the dead, or who attended at the hospitals. By the declarations which these people, from their situations, were able to wring from the dying, they were informed of the state of their houses; nay, it often happened, that by the same means they got possession of their keys. This licence was yet greater in the country, where the distance of the battilles from each other, and the opportunity of going to

them in the night, favoured these criminal expeditions." Loc. cit.

These extracts present a picture of the moral evils which, in conjunction with the physical distresses attendant upon so severe and fatal a malady, render a season of pestilence the most formidable calamity that visits mankind. If the reader is desirous of a more ample detail of its horrors, he may peruse the whole of M. Bertrand's volume; the introduction of Boccaccio, before quoted; the *Traité de la Peste*, published by the physicians of Marseilles; the *Loimologia* of Dr. Hodges; and particularly an interesting *Journal of the Plague Year*, being observations or memorials of the most remarkable occurrences, as well public as private, which happened in London during the last great visitation in 1665. This journal, indeed, has been said to be the production of Daniel de Foe, and not, as its title page expresses, "written by a citizen, who continued all the while in London;" but it contains a true picture of the general consequences of the pestilence.

PLAGUE-Water, Aqua Epidemica, is one of the compound waters of the shops, distilled from mint, rosemary, angelica roots, &c.

PLAINAR, in *Geography*, a town of European Turkey, in Romania; 6 miles S. of Gallipoli.

PLAID, BELTED, in *Military Language*, the ancient garb of the Scots Highlanders, and still worn by some of our Highland regiments. The belted plaid consists of twelve yards of tartan, which are plaited, bound round the waist by a leathern belt, the upper part being attached to the left shoulder.

PLAIN, PLANUS, an epithet applied to various things, generally importing them to be smooth, even, level, or superficial, or simple, obvious, or the like.

In these senses, the words stand opposed to rough, solid, laboured, enriched, &c.

It is a maxim in heraldry, that the plainer the coat, the nearer to antiquity. Plain coats are such as are least encumbered with figures, or charges, and which have nothing in them but what is natural.

PLAIN, in *Heraldry*, is sometimes used for the point of the shield, when coupled square, a part remaining under the square, of a different colour, or metal, from the shield.

This has been sometimes used as a mark for bastardy, and called *champaigne*: for when the legitimate descendants of bastards have taken away the bar, fillet, or traverse, borne by their fathers, they are to cut the point of the shield with a different colour, called *plain*.

PLAIN, used substantively, in *Perspective, Mechanics, Astronomy, &c.* See PLANE.

PLAIN Angle, in *Geometry*, is an angle contained under two lines or surfaces.

It is so called in contradistinction to a *solid* angle.

PLAIN Figure. See PLANE.

PLAIN Triangle, is a triangle included under three right lines, or surfaces; in opposition to a *spherical*, and a *mixt* triangle.

PLAIN Trigonometry is the doctrine of plain triangles, their measures, proportions, &c.

PLAIN Chant, and PLAIN Song, in *Music*. See CHANT, and CANTO FERMO.

PLAIN Counterpoint, is rigidly composed of common chords of note against note, without discords, and in characters of the same length, as in calvinistical and parochial psalmody. But, provided long and short syllables are distinguished, as in the 104th psalm, and the notes in vocal or instrumental music are struck together, it may still be called plain counterpoint. Very pleasing airs, a 4, in the

Greek church, are sung in this manner, not only note against note, but syllable against syllable, which renders the words well accented, and very intelligible.

PLAIN Descant. See DESCANT.

PLAIN Glass, or Mirror, in *Optics*, is a glass or mirror whose surface is flat, or even. See the phenomena and laws of plain mirrors, under the article MIRROR.

PLAIN Scale is a thin ruler, whereon are graduated the lines of chords, sines, tangents, secants, leagues, rhumbs, &c. of ready use in most parts of the mathematics, chiefly in navigation.

See its description and use under SCALE.

PLAIN Tyle. See TYLE.

PLAIN Chart, in *Navigation*, is a sea-chart, wherein the meridians and parallels are represented by parallel straight lines; and where, of consequence, the degrees of longitude are the same in all the parallels of latitude.

See the properties, construction, &c. of this chart under CHART.

PLAIN Sailing, is the art of working the several cases and varieties in a ship's motion on a plain chart.

Plain sailing is founded on the supposition of the earth being a plane or flat; which, though notoriously false, yet, places being laid down accordingly, and a long voyage broken into many short ones, the voyage may be tolerably performed by it, near the same meridian.

In plain sailing it is supposed that by the rhumb line, meridian, and parallel of latitude, there always will be formed a right-angled triangle; and that so posited, as that the perpendicular side may represent part of the meridian, or north and south line, containing the difference of latitude; the base of the triangle represent the departure; and the hypotenuse, the distance sailed. The angle at the vertex is the course, and the angle at the base, the complement of the course; any two of which, with the right-angle, being given, the triangle may be protracted, and the other three parts found.

For the doctrine of plain sailing, see SAILING.

PLAIN Table, in *Geometry, &c.* an instrument used in the surveying of land; whereby the draught, or plan, is taken on the spot, without any future protraction, or plotting.

The plain table, represented *Plate VI. Surveying, fig. 1.* consists of a parallelogram of wood about fifteen inches long and twelve broad; round this goes a boxen jointed frame, by means of which a sheet of paper is fastened tight to the table, so that lines may be conveniently drawn upon it.

On each side of the frame, which may be put on either side upwards, towards the inward edge, are scales of inches subdivided, for the ready drawing of parallel lines. Beside which, on one side are projected the 360 degrees of a circle, from a brass centre in the middle of the table (each degree halved) with two numbers to every tenth degree, the one expressing the degree, the other its complement to 360, to save subtraction; on the other side are projected the 180 degrees of a semicircle, from a brass centre in the middle of the table's length, and at $\frac{1}{4}$ th of its breadth; each degree halved, and every tenth noted with two numbers, viz. the degree and its supplement, to 180°. To one side of the table is fitted a compass, for placing the instrument by; and the whole is fixed by a socket, upon a three-legged staff for a stand, on which it is turned round, or fastened by a screw, as occasion requires. Lastly, to the table belongs an index, which is a ruler at least sixteen inches long, and two broad; usually graduated with scales, &c. and having two sights perpendicularly placed on its extremities; and a sloped edge, called the fiducial edge.

PLAIN Table, Use of the.—To take an angle by the plain table; or to find the distance of two places accessible from the same third.

Suppose DA, DB , (*fig. 2.*) the sides of the angle required: or AB the distance required. Place the instrument horizontally, as near the angle as possible; and assume a point in the paper on the table, *v. gr. c*. To this point apply the edge of the index, turning it about this and that way till through the sights you see the point B : and, in this situation of the ruler, draw by its edge the line ce indefinitely.

After the same manner turn about the index on the same point till through the sights you see the point A ; and draw the right line cd indefinitely. Thus have you the quantity of the angle laid down.

Measure the lines DA, DB , with a chain; and from a scale set off the measures thus found on the respective lines; which suppose to reach from c to b , and from c to a . Thus will cb and ca be proportional to DB and DA . Transfer the distance ab to the same scale, and find its length; the length, thus found, will be the length, or distance of AB required.

2. *To find the distance of two places, one of which is inaccessible, by the plain table.*—Suppose the distance required AB (*fig. 3.*), and A the accessible point. 1. Place the plain table in C ; look through the sights till you see A and B ; and draw ac and cb . Measure the distance from your station to A ; and set it off from the scale upon ca . 2. Remove the table to A , where place it so as that the point a representing A , and the index laid along the line ac , you see backwards the former station C . [Note, in this fixing the instrument, lies the use of the compass; for the needle will hang over the same degree of the card in the first and the second case; so that some set the instrument by the needle alone; others only use it to shorten the trouble, by bringing the instrument nearly to its due position by means of it; and then fixing for good by the back sight]. 3. The instrument fixed, turn the sights to B ; and draw the line ab . 4. On the scale measure the interval ab ; which will be the distance of AB required.

3. *To find the distance of two inaccessible places by the plain table.*—Suppose the distance of AB (*fig. 4.*) required. 1. Choosing two stations in C and D ; in the first, C , place the plain table; and through the sights look to D, B , and A , drawing, by the edge of the index, the lines cd, cb, ca . 2. Measure the distance of the stations C, D ; and set this off from a scale on cd . 3. Removing the table from C , fix it in D ; so as the point d hanging over the place D , and the index lying along the line cd , through the sights you see the former station C . The instrument thus fixed, direct the sight to A and B , and draw the right lines da and db ; lastly, find the distance of ab on the scale, and this will be the distance of AB required. After the same manner may the distance of any number of places be found from two stations; and thus may a field, part of a country, &c. be surveyed.

4. *To take the plot of a field from one station, whence all the angles may be seen with the plain table.*—Placing the instrument in the station, assume a point in the paper, to represent the same, *v. gr. O* (*fig. 5.*); laying the edge of the index to this point, direct it to the several angles of the field, A, B, C, D, E, F , &c. and draw indefinite lines by its edge towards every angle; *viz. Oa, Ob, Oc, &c.*; measure the distance of each angle from the station, *viz. OA, OB, OC, OD, &c.* and from a scale set these off from O on their corresponding lines; the extremities hereof

will give points, which, being connected by lines, will represent the field.

5. *To take the plot of a field, wood, or the like, by going round the same, with the plain table.*—Place the instrument horizontally at the first angle, *v. gr. A*: the needle being on the meridian of the card; assuming a point on the paper to represent it; to that point lay the index, directing it till through the sights you see a mark in the angle B , and draw an indefinite line along it; measure the distance of A and B , and from a scale set it off on the line thus drawn; the extremity of this distance will represent the point B . Remove the instrument to B , where set it so as that the needle hang over the meridian of the card; and so as the index lying along the line last drawn, you see the former station A through the sights: here fasten it, lay the index to the point B , and turn it till through the sights you see the next angle C ; in this situation draw a line, as before, measure the distance BC , and set it off from a scale on the line. Remove the instrument to C , where fixing it by the needle, and the back sight, as before, turn the index on the point C till you see the next angle D ; draw the line, measure, and set off the distance CD , as before, and remove the plain table to E ; where fix it, as before; look to the next angle F , draw the line, measure and set off the distance, &c.

In this manner having compassed the whole field, you will have its whole perimeter plotted on the table; which may be now cast up, and its contents found, as in the article SURVEYING.

Manner of shifting paper on the plain table.—When in large parcels of grounds the plot is found to exceed the dimensions of the plain table, and to run off from the paper, the sheet must be taken off the table, and a fresh one put on: the way of managing which shifting is as follows: suppose H, K, M, Z , (*fig. 6.*) the limits of the plain table; so that having laid down the field from A to B , thence to C and D , you want room, the line DE running off the paper; draw as much of the line DE as the paper will well hold; *viz. DO*. And by means of the divisions on the edge of the frame, draw the line PQ through O , parallel to the edge of the table HM ; and through the point of intersection O , draw ON parallel to MZ . This done, take off the frame, remove the sheet, and put a fresh one (*fig. 7.*) in its stead; drawing on it a line RS near the other edge parallel thereto. Then lay the first sheet on the table, so that the line PQ lie exactly on the line RS , to the best advantage, as at O . Lastly, draw as much of the line OD , on the fresh sheet, as the table will hold; and from O continue the remainder of the line D to E . From E proceed with the work as before to F, G , and A .

Use of the plain table, as a theodolite, semicircle, or circumferentor.—The great inconveniency of the plain table is, that its paper renders its use impracticable in moist weather. Even the dew of the morning and evening is found to swell the paper considerably, and, of consequence, to distort the work. To avoid this inconveniency, and render the instrument useful in all weathers; by leaving off the paper, and setting up a pin in the centre, it becomes a theodolite, a semicircle, or a circumferentor, and is applicable like them.

The plain table, stripped of its paper, becomes either a theodolite, or a semicircle, as that side of the frame, which has the projection of the degrees of a circle, or a semicircle, is turned upwards. If it be to serve for a theodolite, the index (the plain table turning on any point as a centre) is constantly to turn about the brass centre-hole in the middle of the table.

If it be for a semicircle, it must turn on the other brass centre-hole; in both cases it is done by means of a pin raised in the holes. When the plain table is to serve as a circumferentor, screw the compass to the index, and both of them to the head of the staff, with a brass screw-pin fitted for the purpose; so that the staff and table standing fixed, the index, sights, &c. may be turned about, and *vice versa*.

To take an angle by the plain table, considered as a theodolite.—Suppose the quantity of the angle EKG (fig. 8.) required. Place the instrument at K, the theodolite side of the frame upwards, laying the index on the diameter. Turn the whole instrument about, the index remaining on the diameter till through the sights you spy E. Screw the instrument fast there, and turn the index on its centre till through the sights you spy G.

The degree here cut on the frame by the index, is the quantity of the angle sought; which may be laid down on paper by the rules of common protraction.

Thus you may proceed to do every thing with the plain table, as with the common theodolite.

To take an angle with a plain table, considered as a semicircle.—Proceed in the same manner with the instrument, considered as a semicircle, as when considered as a theodolite; only laying the semicircular side upwards, and turning the index on the other centre-hole in the middle of the length, and at about one-fourth of the breadth of the table.

To take an angle with the plain table, considered as a circumferentor.—Suppose the former angle EKG required. Place the instrument at K, the fleur-de-lis towards you. Direct the sights to E, and observe the degree cut by the fourth end of the needle, which suppose 296. Turn the instrument about, the fleur-de-lis still towards you, and direct the sight to G, noting the degree cut by the other end of the needle, which suppose 182. Subtract the less from the greater, the remainder, 114° , is the quantity of the angle sought. If the remainder chance to be more than 180° , then it must be again subtracted from 360. This second remainder will be the angle required; which may be protracted, &c. as under PROTRACTOR. Thus you may proceed to do every thing with the plain table, as with the common circumferentor.

PLAIN Place, in *Geometry*, *locus planus*, or *locus ad planum*, is a term which the ancient geometers used for a geometrical locus, when it was a right line, or a circle, in opposition to a solid place, which was an ellipsis, parabola, or hyperbola.

These plain loci the moderns distinguish into *loci ad rectum*, and *loci ad circumulum*. See LOCUS.

PLAIN Problem, in *Mathematics*, is such a one as cannot be solved geometrically, but by the intersection either of a right line and a circle, or of the circumferences of two circles.

Such is the problem following. Given the greatest side, and the sum of the other two sides, of a right-angled triangle: to find the triangle. Such also is this, to describe a trapezium that shall make a given area of four given lines.

Such problems can only have two solutions, because a right line can only cut a circle, or one circle cut another in two points.

PLAIN du Nord, in *Geography*, a town on the N. coast of Hispaniola; 13 miles E.S.E. of Port de Paix.

PLAINFIELD, a township of America, formerly *St. Andrew's*, in Caledonia county, Vermont, 100 miles N.E. from Bennington; containing 543 inhabitants.—Also, a town-

ship of Hampshire county, Massachusetts, incorporated in 1785, and containing 977 inhabitants; 122 miles W. of Bolton.—Also, a township in Northampton county, Pennsylvania, containing 1439 inhabitants.—Also, a township in the N.W. corner of Cheshire county, New Hampshire, on the E. bank of Connecticut river, which separates it from Hartland in Vermont, incorporated in 1761, and containing 1463 inhabitants.—Also, a post-town in the S.E. part of Windham county, Connecticut, on the E. side of Quinabaug river, which divides it from Brooklyn and Canterbury. The soil is generally rich, and well cultivated, and well watered by the Quinabaug and Moosup rivers, together with many brooks and rivulets. It has two congregational meeting-houses, and an academy, with three handsome buildings appropriated to its use. The same was settled in 1689, and contains 1738 inhabitants; 14 miles N.E. from Norwich.

PLAINT, PLAINTE, in *Law*, the propounding or exhibiting any action, real or personal, in writing.

Hence, the party making this plaint is called plaintiff.

PLAINTAIN *Garden River*, in *Geography*, a river at the E. end of the island of Jamaica, and N. by W. of Point Morant. It has at its mouth a kind of bay, and on it, within land, is the town of Bath.

PLAINTE, in the *Ancient Customs of France*, was a request, or petition, presented to the king, against the judges of the provinces, and afterwards against bailiffs and seneschals for denying justice, or for rendering judgment contrary to the laws of the realm.

For in those days there was no appeal from their decisions; but they all pronounced in the dernier resort; so that the plainte was not directed against the party, but against the judge; who was cited to see his own sentence declared null.

This was a kind of supplement to the way of appeals, which was then shut up. The plaintes, in the Capitulars of Charlemagne, are called *blasphemiz*.

PLAINTIFF, in *Law*, he that sues or complains, in an assize, or in an action personal; as in an action of debt, trespass, deceit, detinue, and the like.

Plaintiff stands opposed to *defendant*.

PLAJOW, in *Geography*, a town of the island of Borneo; 150 miles N. of Banjar-Massin.

PLAISANCE, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; 22 miles W. of Auch. The place contains 1260, and the canton 8049 inhabitants, on a territory of 217½ kilometres, in 20 communes.

PLAISANCE, a town on the middle of the neck of the north peninsula of the island of Hispaniola; 12 leagues S.W. of Cape François.

PLAISANO, a town of Naples, in Calabria Ultra; six miles N. of Oppido.

PLAISE, in *Ichthyology*, the English name for the fish, called by authors *plateffa* and *passer levis*, by some *quadratus*, and the *pleuronectes plateffa* of Linnæus.

It is a flat fish, of a dusky olive-colour, spotted with red on the back, and white on the belly.

The plaise are common on most of our coasts; the best and largest are taken off Rye, on the coast of Sussex, and also off the Dutch coasts. They spawn in the beginning of February.

PLAISTER, in *Building*. See PLASTER, MORTAR &c.

PLAISTER, *Casting in*. See CASTING.

PLAISTER, in *Medicine*. See EMPLASTRUM, and PLASTER.

PLASTERED WALLS. See WALL.

PLAISTOW,

PLAISTOW, in *Geography*, a town of America, in Rockingham county, New Hampshire, containing 424 inhabitants.

PLAISTOW, a village in the parish of West-Ham, Effex. See **WEST-HAM**.

PLAITING, in *Rigging*, denotes braided cordage, made by rope-yarn, &c. twisted together, and then laid one over the other alternately; or the end of a rope opened, and the strands placed together in the same manner.

PLAK, in *Geography*, a town of Hungary; five miles S. of Caschau.

PLAN, a representation of something drawn on a plane. Such are maps, charts, and ichnographies.

PLAN, in *Architecture*, is particularly used for a draught of a building; such as it appears, or is intended to appear on the ground; shewing the extent, division, and distribution of its area into apartments, rooms, passages, &c.

The plan is the first device or sketch the architect makes; it is also called the *ground plot*, *platform*, and *ichnography*, of the building.

PLAN, *Geometrical*, is that in which the solid and vacant parts are represented in their natural proportion.

PLAN, *Raised*, is that where the elevation, or upright, is shewn, upon the geometrical plan, so as to hide the distribution. See **ELEVATION**.

PLAN, *Perspective*, is that conducted and exhibited by degradations, or diminutions, according to the rules of perspective.

To render plans intelligible, it is usual to distinguish the masses with a black wash. The projections on the ground are drawn in full lines, and those supposed over them in dotted lines. The augmentations or alterations to be made are distinguished by a colour different from what is already built; and the tints of each plan are made lighter as the stories are raised.

In large buildings it is usual to have three several plans for the first three stories.

PLAN of a Bastion, in the *Military Art*, is the same with the face of the bastion.

PLAN, in *Ship Building*, the section of a ship, as designed upon paper, previously to the actual building of which, three are the chief, *viz.* the plan of elevation or sheer-plan, the horizontal or half-breadth-plan, the plan of projection or body-plan; these three compose the *sheer-draught*. But it must be observed, that the extreme length, breadth, and height must be determined; by which the three plans aforesaid may be delineated. These may be called the outlines, and the several parts contained within them may be delineated so as to answer the intended purpose; and likewise have a distinct view of the whole design, so that any inconveniencies attending such a disposition may be easily remedied, and the true dimensions of every particular may then be had upon the draught.

The delineating a ship upon a plan is called drawing, and the representation is called a draught. See **SHIP-BUILDING**.

PLAN, in *Geography*, a town of Bohemia, in the circle of Pilsen; 66 miles W.S.W. of Prague. N. lat. 49° 52'. E. long. 12° 47'.

PLAN, *El*, a town of Spain, in Aragon; 15 miles N. of Ainsa.

PLAN Ober, a town of Bohemia, in the circle of Bechin; 12 miles W.S.W. of Crumau.

PLANA, a town of Sweden, in West Gothland; 30 miles E.N.E. of Uddevalla.

PLANA, *La*, a town of Spain, in Valencia; 22 miles E. of Segorbe.

PLANA, or *Tabarca*, a small island in the Mediterranean, near the coast of Valencia, S.E. of cape St. Pola. N. lat. 37° 11'. W. long. 0° 34'.

PLANARIA, in *Ancient Geography*, an island situated on the coast of Italy, in the Ligurian sea, 60 miles from that of Corsica. Pliny.

PLANARIA, in *Vermeology*, a genus of worms of the order Intestina. The generic character is; body gelatinous, flattish, with a double ventral pore; the mouth is terminal. There are forty-nine species, divided into four sections, distinguished as to the number of their eyes or their being without eyes. The animals comprehended under this genus nearly resemble leeches, and like them live in fresh waters.

A. Without Eyes.

Species.

STAGNALIS. Ovate, brown, the fore-part pale. It inhabits the stagnant waters; the body is opaque, a little pointed on the fore-part, pellucid, with two milk-white spots; the eggs are numerous, whitish, placed at the sides.

NIGRA. Oblong, black, and truncate on the fore-part. It inhabits rivers.

BRUNNEA. Oblong, reddish-brown, with a longitudinal black line.

CILIATA. Body long, depressed, and ciliate. It is found in stagnant waters, under duck-weed: it is a very curious creature; the body is grey, appearing as if composed of granulations, with moveable bristles; the organ on the fore-part rotatory.

GULO. Body long, pellucid, and truncate before. This also is found in stagnant waters, under duck-weed; resembles the last, but is without the fringe, the margin all round is tessellate, with extremely fine striæ; it swallows the several species of the Cyclidium which inhabit the same waters, and after a time discharges them again. See **CYCLIDIUM**.

PUNCTATA. Body long, round, and green. Found early in the spring in wet meadows. The body is obtuse before, a little pointed behind, sprinkled with small black dots, and containing five red spherical pellucid eggs.

FLACCIDA. Body long, reddish-brown, with transverse white lines, and a lateral one. It is found among heaps of shells in the bays of Norway; when at rest it rolls itself up spirally, and then gradually dilates itself.

ROSEA. Body long, red. Found in the bays of Norway.

ANGULATA. Body long, reddish-brown, with two white angles on the fore-part. Found in the sandy bottoms of the ocean.

RUBRA. Body oblong, depressed, and of pale red. It inhabits the deeps of the Greenland shores. The body is marked with fine transverse lines above.

VIRIDIS. Body oblong, above convex, with transverse white streaks. Found among the roots of marine fuci.

OPERCULATA. Body subovate, grey, and furnished beneath with a lid which conceals the exsertile tube. Inhabits, though rarely, the sandy shores, particularly among fuci, in the bays of Norway. In appearance it seems to resemble a coffee berry, and moves by bending in its margin, and by means of its marginal folds fixes itself to and ascends other bodies.

SUBULATA. Body long, pointed on the fore-part, and truncate behind. It is found in great plenty among marine conservæ in Greenland, and the muddy bottoms of holes in rocks which constantly retain water, and proceeds with a serpentine kind of motion; but if the proboscis be touched it contracts itself suddenly into a minute cube.

QUADRANGULARIS. Body pale, ovate, very sharp-pointed before, and winged with small curled longitudinal membranes. It is found in ditches, among duck-weed; is very soft, pellucid, of a changeable form, and moves like a slug, leaving a slime on the bodies it passes over; when it meets another animal it draws itself in like a snail.

BICORNIS. Body oval, lanceolate, obtuse at each end, grey cinereous, dotted with black, with two very short divergent tubes on the fore-part. It is a native of those waters in Belgium that are covered with duck-weed: when irritated it fixes itself to other bodies, like the leech, by means of its tubes.

GRISEA. Body grey, dilated, elongated and pointed on the fore-part; the hind part is abbreviated and pointed. It inhabits the waters of lakes, among confervæ.

FULVA. Depressed, broadish, and pointed at each end, with a long black spot down the middle.

VIRIDATA. Oblong, round, green, and somewhat pointed at each end. It inhabits wet meadows in the autumn.

B. With a single Eye.

GLAUCA. The body of this is a little elongated, and cinereous, with a white iris. It is about a line long, pointed before and broadish behind, with sometimes a double black line in the middle of the back and meeting at the ends. A native of the waters.

LINEATA. Body long, above convex and cinereous, with a longitudinal pale line. This species is found on the shores of the Baltic; is about a line and a half long; beneath it is of a pale colour, with a brown patch in the middle, tapering before and dilated behind.

RUTILANS. Linear, with a black eye, and tapering to a point before. This is found in the Baltic, among fuci.

C. With two Eyes.

* **FUSCA.** Black-brown, with a semi-pellucid whitish spot above the tail. It is found in slow streams upon and about aquatic plants. When at rest the body is circular, and seldom above a line in length; when in motion it is linear, and nearly half an inch long; its motion is uniform, smooth, by gliding along the stream.

* **LACTEA.** Body depressed, oblong, whitish, and truncate on the fore-part. It is found in ponds and rivulets, but only in the summer season, and among aquatic plants. When in motion it is about an inch long: the body is marked with a white spot in the middle, the purple viscera elegantly branching round it; the margin is white and very transparent.

TORVA. Depressed, oblong, cinereous, or black and whitish beneath; the iris is white, it is something more than half an inch long.

CRENATA. Depressed, ovate-oblong, pale, with a crenulate margin. A native of Denmark.

TENTACULATA. Depressed, oblong, cinereous, and tubular on the fore-part. Inhabits stagnant waters, and three-quarters of an inch long.

HELLUO. Body ovate, round, green. It inhabits wet meadows, and is not a quarter of an inch long.

OBSCURA. Ovate-oblong, white, and obtuse at both ends. It is found in stagnant waters, and is about a line long, and sub-pellucid.

ROSTRATA. Oblong, hyaline; elongated at the extremity; the eyes are red. It inhabits marshes; about a line long; whitish, but with a purplish mass in the middle.

ATOMATA. Flat, membranaceous, white, with scatter-

ed rufous specks above. It is a native of the bays of Norway, and resembles the *DORIS oblevata*; which see.

CORNUTA. Flat, rather oblong, with a tentaculum or feeler from each side of the head. It inhabits the bays of Norway.

RADIATA. Oblong, rufous, with a white rose-like spot on the back. It inhabits wet woods, and resembles the *Vorticella radiata*.

STRIGATA. Oblong, pale, with three longitudinal lines. It inhabits wet marshes: the body is marked with rufous streaks.

GROSSA. Cylindrical, white with black eyes, and pointed at both ends. It is found among aquatic plants; it varies in size; the body is pellucid, with from five to more than thirty large spherical eggs.

LINEARIS. Long, roundish, and pale yellow. It inhabits wet hollows of woods, about a line and a half long, and ten times as narrow; the margin is pellucid and white.

TERRESTRIS. Linear; above convex, cinereous; beneath white. It is found in moist clumps among moss; it contracts and expands itself like a leech, and moves like a snail; body opaque and viscous.

TETRAGONA. Pale yellow, with four quadrangular lamellæ. It inhabits clear stagnant waters.

CAPITATA. Oblong, cinereous, with a distinct head. Found in the Baltic.

CAUDATA. Body rounded before, and tapering into a tail behind. Inhabits the shores of Greenland, among seawrack.

AURICULATA. Oblong, truncate and emarginate before, and acute behind. Found in the sea-water in Norway. It is a very minute worm, scarcely visible to the naked eye.

FILARIS. Linear, with a filiform contractile tail. Found on the *MADREPORA prolifera*, which see; it is about an inch long and a line broad.

LINGUA. Pellucid, brown-cinereous, and very obtuse at both ends. Found in fish-ponds in the autumn.

GESSERENSIS. Body long, green, and rufous behind the head. This is a native of Denmark, on the *Fucus furcillatus*.

E. With four Eyes.

MARMORATA. Oblong, bluish-grey or pale. Found in wet ditches, about half a line long; intestines glomerate, white, with a large round yellow spot in the middle.

CANDIDA. Body long, whitish, with a clear white line down the middle. It inhabits the shores of Greenland, under stones, and is about two or three inches long.

TRUNCATA. Pale reddish, broadly truncate before, and rather sharp behind.

F. Eyes numerous.

TREMELLARIS. Flat, membranaceous, pale yellow, with a sinuate margin. It is found in the Baltic, and resembles a Tremella, and is nine inches long. The body of this worm is greyish above; the disk is yellowish, with a pinnate line, in the middle, and behind this two white lunules; beneath it is whitish, with three milk-white spots.

PLANCHES, in *Geography*, a town of France, in the department of the Jura, and chief place of a canton, in the district of Poligny; 16 miles S.E. of Poligny. The place contains 333, and the canton 4218 inhabitants, on a territory of 117½ kilometres, in 10 communes.

PLANCHIER, or **PLANCERE**, in *Architecture*, the under part of the corona, or drip; making the superior part of the corniche, between two cymatiums.

PLANCKEN, in *Geography*, a town of Prussia, in Nantangen; 10 miles S.W. of Brandenburg.

PLANCOET, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Dinan; 8 miles N. W. of Dinan. The place contains 635, and the canton 13,522 inhabitants, on a territory of $202\frac{1}{2}$ kilometres, in 12 communes.

PLANCY, a town of France, in the department of the Aube; 8 miles W. of Arcis-sur-Aube.

PLANE, PLANUM, in *Geometry*, denotes a plain figure, or a surface lying evenly between its bounding lines.

Wolfius defines plane, a surface, from every point of whose perimeter a right line may be drawn to every other point in the same.

As the right line is the shortest extent from one point to another, so is a plane the shortest extension between one line and another.

PLANES, *Oblique*. See OBLIQUE.

PLANES, *Parallel*. See PARALLEL.

PLANES are frequently used in *Astronomy*, &c. for imaginary surfaces, supposed to cut, and pass through, solid bodies, and on this foundation it is, that the whole doctrine of conic sections, and of the sphere, turns.

When a plane cuts a cone parallel to one of its sides, it makes a *parabola*; when it cuts the cone parallel to its base, it makes a *circle*. See each respectively.

The sphere is wholly explained by planes, imagined to cut the celestial luminaries, and to fill the areas or circumferences of the orbits; and they are differently inclined to each other; and by us the inhabitants of the earth, the plane of whose orbit is the plane of the ecliptic, their inclination is estimated with regard to this plane. See PLANETS.

PLANE, in *Mechanics*. A *horizontal plane* is a plane level or parallel to the horizon.

The determining how far any given plane, &c. deviates from a horizontal one, makes the whole business of *levelling*; which see.

PLANE, *Inclined*, is a plane which makes an oblique angle with a horizontal plane.

A machine has been contrived for measuring the acceleration of a ball down an inclined plane, and comparing it with that found in bodies falling at liberty. See its description in Mem. de l'Acad. Roy. de Scienc. 1699, p. 343.

The doctrine of the motion of bodies on inclined planes makes a very considerable article in mechanics; the general principle of it has been already illustrated under MECHANICAL POWERS, and the substance of it is as follows:

Laws of Descent of Bodies on inclined Planes.—I. If a body be placed on an inclined plane, its relative gravity will be to its absolute gravity as the height of the plane, *e. gr.* A B (*Plate XXXV. Mechan. fig. 1.*) to its length A C. For, the construction being as in the figure, it is evident that the absolute gravity, tending in a direction perpendicular to the horizon, is to the relative gravity in the direction of the plane, as D F : F G or D E, *i. e.* because the triangles D E F and B A C are equiangular, :: C A : A B.

Hence, 1. Since the ball D only gravitates on the inclined plane with its relative gravity, the weight L, applied in a direction parallel to the length of the plane, will retain or suspend it, provided its weight be to that of the ball, as the altitude of the plane B A is to its length A C.

2. If the length of the plane C A be taken for the whole sine or radius, A B will be the sine of the angle of inclination A C B. The absolute gravity of the body, therefore, is to its respective gravity applied to the inclined plane; and, therefore, also the weight D to the weight L acting accord-

ing to the direction D A, which sustains it, as the whole sine is to the sine of the angle of inclination.

3. Hence the respective gravities of the same body on different inclined planes, are to each other as the sines of the angles of inclination.

4. The greater, therefore, the respective gravity is, the greater is the angle of inclination.

5. As, therefore, in a vertical plane, where the inclination is greatest, *viz.* perpendicular; the respective gravity degenerates into absolute; so in a horizontal plane, where there is no inclination, the respective gravity vanishes: and hence it appears, that the inclination of the plane may be so small, that the greatest weight may be sustained on it by the smallest power.

II. To find the sine of the angle of inclination of a plane, on which a given power will be able to sustain a given weight. Say, as the weight is to the given power, so is the whole sine to the sine of the angle of inclination of the plane. Thus, suppose a weight of 1000 be to be sustained by a power of 50, the angle of inclination will be found 2 : 52'.

III. If the weight L descend according to the perpendicular direction A B, and raise up the weight D in a direction parallel to the inclined plane, the height of the ascent of D will be to that of the descent of L, as the sine of the angle of inclination C to the whole sine.

Hence, 1. The height of the descent C D of the weight L, is to the height of ascent D H of the weight D, reciprocally as the weight D to the equivalent weight L.

2. Since then $C D \times L = D H \times D$, and the actions of the equponderating bodies D and L are equal; the moments of the weights D and L are in a ratio compounded of their masses, and the altitudes through which they ascend or descend in a plane either inclined or perpendicular.

3. The powers that raise weights through altitudes reciprocally proportional to them, are equal. This Des Cartes assumes as a principle whereby to demonstrate the power of machines.

Hence we see why a loaded waggon is drawn with more difficulty up an inclined than on an horizontal plane: as being pressed with a part of the weight which is to the whole weight in a ratio of the altitude of the plane, to its length.

IV. Weights E and F, *fig. 2.* equponderating upon inclined planes A C and C B of the same height C D, are to each other as the lengths of the planes A C and C B.

S. Stevinus gives a very pretty demonstration of this theorem, which, for its easiness and ingenuity, we shall here add. Put a chain, whose parts do all exactly weigh in proportion to their length, over a triangle G I H (*fig. 3.*); it is evident the parts G K and K H do balance each other. If then I H did not balance G I, the preponderating part will prevail; and there would arise a perpetual motion of the chain about G I H: but this being absurd, it follows that the parts of the chain I H and G I, and consequently all other bodies which are as the lengths of the planes I H and I G, will balance each other.

V. A heavy body descends on an inclined plane, with a motion uniformly accelerated.

Hence, 1. The spaces of descent are in a duplicate ratio of the times, and likewise of the velocities; and therefore in equal times they increase according to the unequal numbers, 1, 3, 5, 7, 9, &c.

2. The space passed over by a heavy body descending on an inclined plane is subduple of that which it would pass over in the same time, with the velocity it has acquired at the end of its fall.

3. Heavy bodies, therefore, descend by the same laws on inclined planes as in perpendicular planes. Hence it was, that Galileo, to find the laws of perpendicular descent, made his experiments on inclined planes, because the motions are slower in the latter than the former; as in the following theorem.

VI. The velocity of a heavy body descending on an inclined plane, at the end of any given time, is to the velocity which it would acquire in falling perpendicularly in the same time, as the height of the inclined plane is to its length.

VII. The space passed over by a heavy body on an inclined plane AD (*fig. 4.*), is to the space AB it would pass over in the same time in a perpendicular plane, as its velocity on the inclined plane is to its velocity in the perpendicular descent, at the end of any given time.

Hence, 1. The space passed over on the inclined plane is to the space it would descend in the same time in the perpendicular plane, as the altitude of the plane AB to its length AC ; and, therefore, as the sine of the angle of inclination C , to the whole sine.

2. If, then, from the right angle B , a perpendicular be let fall to AC ; $AC : AB :: AB : AD$. So that in the same time wherein the body would fall perpendicularly from A to B ; in an inclined plane it will descend from A to D .

3. The space, therefore, of perpendicular descent being given in the altitude of the plane AB ; by letting fall a perpendicular from B to AC , we have the space AD to be passed over in the same time on the inclined plane.

4. In like manner, the space AD , passed over on the inclined plane, being given, we have the space AB through which it would descend perpendicularly in the same time, by raising a perpendicular at D meeting the altitude of the plane in B .

5. Hence in the circle $CDEF$, *fig. 5*, the body will descend through all the planes AD , AE , AF , AC , in the same time; *viz.* in that time wherein it would fall through the diameter AB , supposing that perpendicular to the horizontal plane LM : because all the angles D , E , F , C , in the semicircle, are right angles.

VIII. The space AD , (*fig. 4.*) passed over an inclined plane AC being given, to determine the space which would be passed over in any other inclined plane in the same time.

From the point D erect a perpendicular DB , meeting the altitude AB in B ; then will AB be the space through which the body would fall perpendicularly in that time. Wherefore, if from B a perpendicular BE be let fall to the plane AF ; AE will be the space in the inclined plane which the body will pass over, in the same time wherein it falls perpendicularly from A to B ; and consequently AD will be the space in the other inclined plane AC , which it passes through in the same time.

Hence, since AB is to AD as the whole sine to the sine of the angle of inclination C ; and AB is to AE as the whole sine to the sine of the angle of inclination F ; the spaces AD and AE , which the body will pass over in the same time on different inclined planes, are as the sines of the angles of inclination C and F , and reciprocally as the respective gravities on the same planes. And, consequently, they are also reciprocally as the lengths of planes equally high, AC and AF . Whence the problem may be resolved various ways by calculation.

IX. The velocities acquired in the same time on different inclined planes, are as the spaces passed over in the same time.

For AD , AB , and AE , are the spaces passed over in

the same time; and since $AB : AC ::$ the velocity acquired in passing over AD to the velocity acquired in passing over AB ; $AC : AF ::$ the velocity acquired in passing over AE to the velocity acquired in passing over AB ; $AB : AC :: AD : AB$; and $AB : AF :: AE : AB$; the velocity acquired in passing over AD is to the velocity acquired in $AB :: AD : AB$, and the velocity acquired through AE to the velocity through $AB :: AE : AB$; therefore the velocities acquired in the same time in passing over AD and AE will be as the spaces of AD and AE passed through in the same time.

Hence, also, they are as the sines of the angles of inclination C and F ; reciprocally as the respective gravities on the same planes; and reciprocally as the lengths of equally high planes AC and AF .

X. A body descending on an inclined plane AC , when it arrives at the horizontal line CB , has acquired the same velocity which it would have acquired in a perpendicular descent AB , to the same horizontal line CB .

For AD is the space passed over in the same time with AB ; and, therefore, the celerity acquired in passing through AB is to that acquired through AD as AC to AB : but the celerity through AC is to that acquired through $AD :: \sqrt{AC} : \sqrt{AD}$; and since $AC : AB :: AB : AD$, $AC : AD :: AC^2 : AB^2$, and $\sqrt{AC} : \sqrt{AD} :: AC : AB$: consequently the celerity acquired through AC is to that acquired through AD as AC is to AB : therefore the celerity acquired through AC is equal to that acquired through AB .

Hence 1. A heavy body descending through different inclined planes AC , AG , AF , hath acquired the same velocity when it arrives at the same horizontal line BF .

Hence also, 2. A body, continuing its descent through several contiguous inclined planes, acquires the same velocity which it would acquire in descending perpendicularly to the same horizontal plane.

XI. The time of descent along an inclined plane AC , is to the time of perpendicular descent through AB , as the length of the plane AC , to its altitude AB : but the times of descent through different inclined planes equally high, AC and AG , are as the lengths of the planes.

For the time through AC is equal to the time in which AC would be described uniformly with half the celerity acquired in C ; and the time through AB is equal to that in which AB would be described uniformly with half the celerity acquired in B ; but these celerities are equal; consequently the times are as AC and AB . In the same manner it might be shewn, that the times of descent through AC and AG , are as AC and AG .

XII. If the diameter of a circle AB (*fig. 5.*) be perpendicular to the horizontal line LM ; a body will descend from any point of the periphery D , E , or C , to B , along an inclined plane DB , EB , and CB , in the same time in which it will descend through the diameter AB .

For, letting fall the perpendicular CG , the time in which GB is described is to the time in which BC is described as $BG : BC$; but the time in which BC is described is to the time in which AB is described in the subduplicate ratio of BG to AB ; *i. e.* because $BG : BC :: BC : AB$, in the ratio of BG to BC : consequently, the time of descent through GB has the same ratio to the time of descent through BC and the diameter AB ; therefore the time in which BC is described is equal to the time in which AB is described, &c. Hence,

XIII. The descents of bodies through a semicycloid DEF (*fig. 6.*), and through any arc thereof DG , are always

ways isochronal, or performed in the same time; on which principle is founded the doctrine of pendulums vibrating in a cycloid. See CYCLOID and PENDULUM.

The inclined plane is a mechanical power, often applied with advantage to practical purposes, and forms a very useful part of machinery in the elevation of great weights. It is supposed that in all the edifices of remote antiquity, where great masses of stone were employed, as in the pyramids of Egypt, and the druidical temples of this country, these vast blocks were elevated on inclined planes of earth, or of scaffolding, with the assistance also of levers and rollers. Inclined planes are frequently used for drawing boats out of one canal into another: and sometimes the local circumstances are such, that this may be done with great convenience, merely by allowing a loaded boat to descend, and to turn the axis which raises an empty one. An example of this may be seen, on a large scale, in the duke of Bridgewater's canal. This canal is extended, above ground, for forty miles on one level; an underground navigation, twelve miles long, joins it at Worsley, leading to the coal-mines under Walkden moor. At a height of $35\frac{1}{2}$ yards above this, is another subterraneous portion, nearly six miles in length. The connection between these levels is formed by an inclined plane: the boats are let down loaded, and proceed three miles along the tunnel into the open canal. The inclined plane is fixed in a stratum of stone, which fortunately has the most eligible inclination of 1 in 4, and is 33 yards in thickness, affording the most advantageous means of fixing every part of the machinery with perfect security. The whole length of the plane is 151 yards, besides a lock of 18 yards at the upper end.

Inclined planes are used in many places for raising and lowering coal-wagons, so that one is brought up by the force of that which descends. Inclined planes are also universally employed for facilitating the ascent of heights, by men or by animals; they may be either uniform, as roads, or the general inclination of the surface may be superadded by the formation of separate steps or stairs. The inclination of the surface may be governed by the proportion of the strength of the animal to its weight, the force required to support any weight on a plane being to the whole weight as the height of the plane to its length, and if the plane be a little less inclined than the exact equilibrium would require, the animal will be able to acquire a sufficient velocity at first to carry it easily up the ascent with a motion nearly equal. The strength of a labourer may be advantageously employed in ascending a given height by a flight of steps, and placing himself on a stage which may raise a weight by its descent; but it appears that the force of other animals is less calculated for exertions of this kind.

PLANES, Laws of Ascent of Bodies on inclined.—I. If a body ascend in a medium void of resistance, in any direction, whether perpendicular, or along an inclined plane; its motion will be uniformly retarded.

Hence, 1. A body ascending either perpendicularly or obliquely, in such a medium, passes over a space which is subduplicate of that it would pass over in the same time on an horizontal plane, with an uniform celerity equal to that it has at the beginning of its motion.

2. Such spaces, therefore, performed in equal times, decrease in a retrograde order, as the uneven numbers 7, 5, 3, 1; and therefore the ascent is so much impeded; and consequently, when the impressed force is exhausted, the body will descend again by the force of gravity.

3. They are, therefore, inversely as the spaces described in the same times by a body descending through the same altitude. For, suppose the time divided into four parts; in

the first moment, the body A descends through the space 1, and B ascends through 7; in the second, A descends through 3, B ascends through 5, &c.

4. Hence a body, rising with an impressed force, ascends to that altitude, from which it must fall to acquire that velocity in falling with which it ascended.

5. Hence, by falling, it acquires a force to rise again to the height from which it fell.

II. The time in which a body ascends to a given altitude, being given; to determine the space passed over each moment.

Suppose the same body to descend from the same altitude in the same time; and find the spaces passed over each moment.

These, taken inversely, are the same with the spaces of ascent required.

Suppose, *v. gr.* a body projected perpendicularly, to ascend through a space of 240 feet in four seconds; and the spaces of ascent performed in the several times required; if now the body had descended, the descent in the first minute had been 15 feet, in the second 45, in the third 75, in the fourth 105, &c. The descent therefore will be in the first moment 105, in the second 75, &c.

III. If a body descend either perpendicularly through AD (*fig.* 6.), or in any other surface FED, and with the velocity it has there acquired, again ascend along another surface DC, at points equally high, *e. gr.* at G, H, and Q, it will have the same force, and the same velocity.

Hence, if a body descend along any surface FED, and again descend along another similar and equal surface DGC, it is the same as if it passed over the several parts of the same line twice.

Whence, the times of ascent and descent through equal spaces are equal.

On this principle are founded the construction and use of pendulums.

PLANE of Gravity, or gravitation, is a plane supposed to pass through the centre of gravity of the body, and in the direction of its tendency; that is, perpendicular to the horizon.

PLANE of Reflection, in Catoptrics, is a plane which passes through the point of reflection; and is perpendicular to the plane of the glass, or reflecting body.

PLANE of Refraction is a plane drawn through the incident and refracted ray.

PLANE of the Horopter, in Optics, is a plane that passes through the horopter AB (*Plate VI. Optics, fig.* 3.) and is perpendicular to a plane passing through the two optic axes IC and CH. See HOROPTER.

PLANE of the Projection, in the Stereographic Projection of the Sphere, is the same with the perspective plane; which see.

PLANE of a Dial, or Dial-plane, the surface whereon a dial is drawn. See DIAL.

We have horizontal, vertical, inclining, declining, reclining, deinclining, direct, oblique, &c. dial-planes. See DECLINER, RECLINER, DIRECT, &c.

PLANE, Declination and Inclination of a. See DECLINATION and INCLINATION.

For the method of finding both, see DECLINATOR.

PLANE Glass, Mirror, Figure, Number, Problem, &c. See PLAIN Glass, Mirror, Number, Figure, Problem, &c.

PLANE, Geometrical, in Perspective, is a plane parallel to the horizon, whereon the object to be delineated is supposed to be placed.

This plane is usually at right angles with the perspective plane. See PERSPECTIVE.

PLANE, Horizontal, is a plane passing through the spectator's eye, parallel to the horizon, cutting the perspective plane, when it is perpendicular to the geometrical one, at right angles.

PLANE, Objective, is any plane situate in the horizontal plane, whose representation in perspective is required.

PLANE, Perspective, is a plain pellucid surface, ordinarily perpendicular to the horizon, and placed between the spectator's eye and the object he views; through which the optic rays, emitted from the several points of the object, are supposed to pass to the eye, and in their passage to leave marks that represent them on the said plane.

Some call it the *table*, or *picture*, because the draught or perspective, of the object, is supposed to be thereon; others the *section*, from its cutting the visual rays; and others the *glass*, from its supposed transparency. See PERSPECTIVE.

PLANE, Vertical, a plane passing through the spectator's eye, perpendicular to the geometrical plane, and usually at right angles to the perspective plane. See PERSPECTIVE.

PLANE, a tool used by artificers who work in wood, to produce straight, flat, and even surfaces upon that material. Almost all trades which fabricate articles of wood, employ planes at times; but as joiners make a greater use of these tools than any others, they are usually considered as joiners' and carpenters' tools. Planes have been, of late years, used by some artists to produce flat surfaces in metals. A plane operates to cut off a thin chip or shaving from the wood on which it is applied, by the sharp edge of a steel cutter or broad chissel, called, very improperly, the *plane iron*: this is fixed in a hole made through a wooden block, called the *plane stock*, and the edge of the iron projects a very small quantity through the lower side of the stock, called the *face* of the plane; the surface of which face is made a perfectly true plane. The iron is fixed in an inclined position in the hole through the stock, by means of a *wedge* driven in before it, to jamb it fast in the hole, which being wider than the thickness of the iron, leaves an aperture before the iron, called the *mouth* of the plane: this is very narrow where it opens in the lower side or face, but grows wider as it rises up through the stock; the wedge is also cut forked, to allow more room for the shavings which the plane iron cuts to pass up before it through the mouth. When a plane of this kind is applied with its face upon the surface of a piece of wood, and pressed down upon it whilst it is moved forwards, the edge of the iron penetrates the wood to the depth which it projects through the face, and removes a shaving of that thickness and the whole breadth of the edge of the iron, the shaving turning up before the iron passes through the mouth, and escaping. The inclination of the iron makes it cut easily; and if the iron is *set fine*, that is, if the edge projects but very little beyond the face, it will remove very thin shavings, and produce a flat and smooth surface: on the other hand, if it is *set rank*, that is, with a considerable projection, it will cut away very fast, producing a flat though rough surface, and quickly reducing the wood to its intended thickness: if the wood has an irregular surface, it soon reduces it to a plane, because the face, being flat, will not suffer the edge of the iron to descend into the hollow places, but removing all the eminences it passes over till they are reduced to one level.

This is a general description of several kinds of planes, which are all known by different names, from their different dimensions and purposes. Joiners use the *jack plane*, the *long plane*, *trying plane*, *shooting plane* or *jointer*, and the *smoothing plane*; all which they denominate *bench planes*, be-

cause the wood they are used upon is generally laid on the work-bench. They have also the *straight block* for straightening short edges, *rebating planes* for forming rebates; others, for the same use, are called the *moving fillister*, *fast fillister*, and *side-rebating plane*. The *plough* is a narrow plane, provided with apparatus to guide it, in moving straight, to plow a groove or trench at any required distance from the edge of a board or other piece of wood, and to any depth or width. The *dado grooving plane* is also for forming grooves.

There are several other tools, which, having an iron fitted into a stock, are called planes, because they cut in the same manner, though, in strictness, they are not planes, for they do not make plane surfaces: these are *moulding planes*, with faces and cutting edges curved, to produce all the varieties of ornamental mouldings, and which are known by the names of *snipe's-bills*; *side snipe's-bills*, *beads*, *hollows* and *rounds*, *ovolos* and *ogees*. The varieties and different sizes of these form a vast number, with which every complete joiner is furnished. It is impossible to describe the terms applied to these tools without figures, as they are arbitrary, though generally known among workmen. The faces of all these planes are straight in the direction of their length, but a section across the face is the impression or reverse of the moulding they are intended to make, and the edge of the iron is curved to correspond with this curve when in its place, but will in reality be a very different figure, because it is inclined to the face of the plane at an angle of about forty-five degrees. Another distinction between these and the bench planes is, that their mouths do not open so as to discharge the shaving through the stock at the top thereof, but the wedge completely fills the hole, and the shaving passes out sideways through a hole for that purpose; in some, these apertures are on the right, and in others on the left side; in the first case the shaving is said by the workmen to be thrown on the bench, that is, upon the right side of the plane; but when the orifice of discharge is on the left, and consequently the shaving thrown upon the left, then the plane is said to throw the shaving off the bench. The *compass plane* is used by coach makers, cabinet makers, &c.; it is made with a convex face, formed to an arc of a circle in the direction of its length, and it therefore forms the concave surface of a cylinder. The *forkstaff plane* is straight in the direction of its length, but its face is made concave in its breadth, to the arc of a small cylinder; the edge of the iron is of course curved in the same manner, and it planes cylindrical surfaces. Coopers also employ long and heavy planes to form the edges of the staves of barrels; these are mounted in an inclined position on legs like a stool, with their faces upwards, and the stave is drawn backwards and forwards upon them.

Planes are so necessary for all kinds of work, that any who intend to work in wood, should understand the structure and the manner of using them. The *jack plane* is used for taking off the rough and prominent parts from the surface of the wood, and reducing it nearly to the intended thickness, in coarse shavings or slices. The stock of this plane is about seventeen inches in length, three inches high, and three and a half inches broad; all the sides are straight and at right angles to each other: the mouth is cut through the solid of the stock to receive the iron, and hold it at such an elevation, as to make an angle of forty-five degrees with the face of the plane; the iron is a thin metal plate, one side consisting of iron the other of steel; the lower end of the iron is ground to an acute angle off the iron side, forming a sloping part called the *basil* of the iron, so as to bring the steel side to a sharp edge: the wedge which fixes the iron in its place, is

PLANE.

let into two grooves of the same form, on the sides of the opening or mouth: two sides of the wedge are parallel, and it is forked or cut away in the middle, leaving the sides like two prongs, to fill the lower part of these grooves; this allows the shaving to pass up without obstruction before the wedge: for the mouth or opening through the flock must be uninterrupted from the face to the top, and must be no wider on the face of the plane, than is sufficient for the thickest shaving to pass with ease; and as the shaving is discharged at the upper side of the plane, the opening through it must expand or increase from the face to the top, so as to prevent the shavings from sticking therein. A handle, called the *tote*, is fixed to the upper side of the flock, immediately behind the iron; it is formed to the shape of the hand, and direction of the motion, so as to produce the most power in pushing the plane forward.

A workman in using the jack plane, lays the piece of wood on the *bench* parallel to its sides, with the farther end lodged against the *bench-book*; then laying the fore-part of the plane upon the hind end of the wood, with the right hand he takes the handle, and pressing with his left upon the fore end, thrusts the plane forward in the direction of the fibre of the wood and length of the plane, until he has extended the stroke the whole length of his arm, the shaving being discharged at the orifice; he then draws back the plane, and repeats the operation in the next adjacent rough part, proceeding in this manner until he has removed the rough parts throughout the whole breadth. He then steps forwards the distance of the length he has planed, and operates upon another length in the same manner, proceeding this way by steps, until the whole length is gone over and rough planed. To do this is very easy; but a workman will not make good progress nor do clean work, unless he has first adjusted his tool properly for the work. The methods of doing this are nearly the same for all planes. The first care is to obtain a sharp cutting edge to the iron; if it requires grinding on the grindstone, the carpenter places his two thumbs under the iron, and the fingers of both hands above, laying the basil side to the grindstone, and holding it to the angle he intends it shall make with the steel side of it, keeping it steady while the stone revolves; and pressing the iron to the stone with his fingers; in order to prevent the stone from wearing the edge of the iron into irregularities, he moves it alternately from edge to edge of the stone, with so much pressure on the different parts as will reduce it to the required bevel, and make the edge straight.

The basil being brought to a proper angle, and the edge to a regular and slight curvature, the roughness occasioned by the gritty particles of the stone are taken away by rubbing its edge on a smooth flat hone or Turkey stone, sprinkled with olive oil on its surface. As the basil is generally ground, to give a more acute angle than the edge of the iron would stand, for the quicker dispatch of wetting it, the face of the iron is inclined nearer to the perpendicular, while it is rubbed backwards and forwards with the same inclination throughout. Every time the iron becomes dull or blunt by use, the sharpening is produced by grinding on the rubber-stone, or flat grindstone, or on a Turkey stone; but in repeating this, after the edge gets thick, it requires so much time to bring it up to an edge, that recourse must be had to the grindstone. The iron being thus sharpened, must be fixed in the plane by its wedge: the projection of the cutting-edge must be just so much beyond the face of the plane, as that the workman may be able to work it freely in the act of planing, and must be regulated by the stuff to be wrought; whether it is hard or soft, cross-grained or curling; so that a man may be able to perform the most work, or reduce the sub-

stance most in a given time. If the stuff is good and clean-grained, it is evident that a considerable projection may be allowed, as a thicker shaving may be taken: the extreme ends of the edge of the iron must never enter the wood, as this not only retards the progress of working, but chocks and prevents the regular discharge of the shavings at the orifice of the plane. The projection of the cutting-edge is called *iron*, and the plane is said to have more or less iron, as the projection is greater; when there is too much iron he knocks with a hammer on the fore end of the top of the flock, and the blows will loosen the wedge, and raise the iron in a certain degree, and the head of the wedge must be knocked down to fix it again.

When he has occasion to take out the iron to sharpen it, he strikes the fore end of the top of the flock smartly with the hammer, which loosens the wedge and the iron.

All the other bench planes are adjusted in the same manner, and indeed do not differ, except in dimensions, as we shall explain, from the jack plane. Of late years, a great improvement has been introduced in the irons of planes, to cause them to cut smooth; these are called double ironed: they were at first only used in the finest shooting planes, but the advantages have been found so great, particularly in planing bad wood, that they have become general for all sorts of planes. The double iron consists of a second iron, with a reversed basil screwed against the front side of the iron, so that its edge lies against the iron at a very small distance from, and parallel to, the cutting edge; and applying closely to the steel side of the iron, it forms an inclined plane, which turns the shaving over immediately after it is separated or cut up by the edge, and thus it prevents the iron from splitting the shaving deeper down than it will afterwards cut, and therefore leaving a rough or torn surface. This second iron is called the cover of the iron; and the basil of its edge, instead of being ground flat, as that of the iron, is rounding: the screw, which binds the cover upon the iron, passes through a slit in the cover, and thus admits of its edge being adjusted at any required distance from the cutting edges of the iron, and this distance depends altogether on the nature of the wood the plane is to be worked upon. If the stuff is clean-grained, the edge of the cover may be set at a considerable distance, because the difficulty of pushing the plane forwards becomes greater, as the edge of the cover is nearer the edge of the iron, and the contrary when more remote: this is occasioned by the edge of the cover turning the shaving over immediately it is cut up.

The *trying plane* is usually twenty-two inches long, three-quarters broad on the face, and three in height; it does not differ from the jack plane, except in having a double handle, adapted for greater force: in use, it succeeds the operation of the jack plane, to straighten the wood, and remove the ridges left by the former; it is set with less iron, and cuts a finer shaving: the mouth is also much narrower. When it is used upon a long piece of work, the workman takes every shaving the whole length, by stepping forwards, instead of stopping at arm's length, as with the jack plane. The shaving of this plane, though finer, is so much broader than the jack, that it requires as much force to push it forwards.

The *long plane* is set very fine for finishing work which is to be very straight; it is twenty-six inches long, three and a half broad, and three inches in height.

The *shooting plane*, or *jointer*, is the longest, and most correct plane used; it is employed after all the others, chiefly in shooting the straight edges of boards which are to be jointed together; it is generally made two feet and a half long,

PLANE.

long, three inches and a quarter broad, and three and a half high; it is used like the others, but with great care to move it steadily from one end of the work to the other, without pressing it down, as that might spring the plane, or the work, and cause the iron to cut when the work was something hollow, whereas the object is to make a perfectly straight edge. The face of this plane must be kept quite true, and therefore it is a great object to make it of a fine piece of clean-grained, hard beech, well seasoned, that it may not warp, or vary, by the weather.

The *smoothing plane* is very short, without any handle, and its sides are curved, so that it very much resembles a coffin; it is seven inches and a half long, three broad at the mouth, and two inches and three quarters in height; it is used for finishing work when put together, and to give the greatest degree of smoothness to the wood, for which purpose it is set with as fine an edge as possible.

Rebating planes are used for cutting out rebates; these are a kind of semi-grooves upon the edge of a board, or other piece of wood, formed by cutting down or reducing a small part of the breadth of the board to half, more or less, of the general thickness: by this means, if a rebate is cut on the upper side of one board, and the lower side of another, the two may be made to overlap each other, without making them any thicker at the joint. Rebates are also used for ornamenting mouldings, and many other purposes in joiners' work. The planes for cutting them are of different kinds, some having the cutting edge at the side of the iron and of the stock, others at the bottom edge of the iron and the face of the stock, and others cutting in both these directions; the former, being used to smooth the side of the rebate, are therefore called side-rebating planes; whilst the others are used for smoothing the bottom. There is also a third sort, called *fillisters*, used for sinking, or cutting away the edge of the piece of wood to form the rebate, leaving it for the others to smooth the surfaces when cut. The rebate planes are about nine inches and a half long, and of various widths upon the face, from half an inch to an inch and three quarters; in all cases they have the mouth and the edge of the iron coming out at one edge of the face, and the side of the iron also exposed at one of the upright sides of the stock, whether it is formed with a cutting edge there or not: this exposed side is either on the right or left, and they are named accordingly. In all cases they throw the shaving out on the side, instead of at the top of the stock. The cutting edges and mouths are generally situated obliquely across the face, instead of being at right angles to the length of the plane, as in others.

The *moving fillister* is a rebating plane, which has a ruler of wood, called the *fence*, fixed upon its face by screws in the direction of its length, and exactly parallel to the edge of the face; it therefore covers part of the length of the cutting edge, and can be fixed at any required distance from the edge, to leave more or less of the cutting edge exposed, and this quantity will be the breadth of the rebate it will cut; because when it is used, the edge of the fence is applied against the edge of the piece to be rebated, and thus gauges the breadth its iron shall cut away. The cutting edge of this plane is not situated at right angles to the length of the stock, but has an obliquity of about forty-five degrees, the exposed side of the iron being more forwards than the other. By this obliquity, when the plane is worked, it has a tendency or drift to run farther into the breadth of the wood, but as the fence, sliding against the edge, prevents this, the drift always keeps the fence in contact with the edge, without the

attention of the workmen; it also causes the iron to cut the bottom of the rebate smoother, particularly in a transverse direction to the fibres, or where the stuff is cross-grained, than could otherwise be done, when the steel face of the iron is perpendicular to the vertical sides of the plane. The principal use is, however, to contribute, with the form of the cavity, to throw the shaving into a cylindrical form, and thereby making it issue from one side of the plane. The iron is what is called shouldered, that is, the lower part or shoulder where the edge is, has double the width of the upper part, which is received into the mortise, and jammed fast by the wedge. It is the edge of this wide part only which is exposed at the side of the stock. Besides this principal iron, there is another small iron, called the tooth, which precedes the other, to scratch or cut a deep crack at the width of the rebate, thus making the shavings which the iron cuts up from the bottom separate sideways from the rest of the wood. This tooth is inserted in a vertical mortise through the stock, between the fore end of the stock and the iron. The lower end of this little iron is ground with a bevel on the inside, so as to bring the bottom of the narrow side of the iron to a very convex edge; it is fastened by a wedge passing down before it in the mortise in the stock. The use of this tooth is principally for cutting the wood transversely when wrought across the fibres, and by this means it not only cuts the vertical side of the rebate quite smooth, but prevents the iron from ragging or tearing the stuff. The iron between the fence and the edge of the face of the plane, must project the whole breadth of the uncovered part of the face, otherwise the wood of the plane will bear it up, and prevent the plane sinking as it cuts away the rebate, and the edge of the tooth or little iron should stand out a little farther on the side of the plane than the iron. The depth of the rebate which this plane will cut, is regulated by a stop fixed on the outside of the plane, at the intended height above the level of the face: then, when the plane has penetrated or sunk the intended depth of the rebate, the stop comes to bear upon the solid of the wood beyond the rebate, and bears it off from cutting any longer. The stop is a piece of brass, which moves in a vertical groove made in the side of the stock, between the iron and the fore end of the plane; in this it is moved up and down by a screw, which is inserted in a vertical perforation from the top of the plane to the groove, and passing through a part projecting from the stop into the groove: the upper part of the screw is formed to a thumb-nut, to turn it round by, and it is so confined by proper collars, that it can neither move up nor down; but being turned, the inclination of the threads will rise or fall according to the direction in which the thumb-screw is turned, and cause the stop to move up and down in the groove on the side of the plane, thus regulating it at pleasure to the depth to which the rebate is required to be sunk.

In grinding and fixing the iron of this plane, it is necessary that the cutting edge of the iron should stand equally prominent in all parts out of the face, otherwise the plane cannot make shavings of an equal thickness; and, consequently, instead of keeping the vertical position, will, as it proceeds, become deeper on the side on which the shavings are thickest, and then the part cut away will not be regular, for the bottom of the rebate will not be parallel to the upper surface of the wood, and the side which ought to have been vertical, will be a kind of a ragged curved surface, formed by as many gradations or steps in the depth as the number of shavings.

The *scjib fillister* differs in several particulars from the moving

ing fillister: the breadth of the iron is something more than the whole breadth of the sole, so that the extremities of the cutting edge are in a small degree without the vertical sides of the stock: the fence is adapted to be moved to a considerable distance, not being fixed, as in the moving fillister, by screws upon the face, but sustained by two bars fixed fast to it, which pass through the two vertical sides of the stock, at right angles to the sides, fitting tight in the two holes through which they pass; these bars are made rounding upon the upper side and flat on the lower side: at the point where they are united to the fence, they have thicker parts, or shoulders, projecting downwards, because it is necessary to have the fence fixed on a lower level than the face of the plane: the ends of the bars are ferruled, to prevent splitting when the ends are struck with a mallet, in order to move them in the holes through the stock, and this brings the fence either nearer or more remote from the stock, as may be wanted; and to fix it fast, when so adjusted, two small tapering pieces of wood, called keys, are inserted into two small wedge-like mortises, cut at the sides of the mortises in which the bars pass through the stem; these wedges being drawn in, they will stick fast, and press against the bars, keeping them fast at all points, and thereby regulate the distance of the fence from the vertical side of the stock. This plane is generally employed to rebate narrow pieces of wood, such as sash frames; and the fence is applied against the opposite edge of the wood to that on which the rebate is to be formed.

The *plough* is a plane with a very narrow face, made of iron, fixed beneath a wooden stock, and projecting down from the wood of the stock, the edge of the iron being the full width, or rather more, than the face; it is guided by a fence with two bars, like the fillister above described, to make or plough out a groove of the width of the iron, and at any required distance from the edge of the wood; it has also a similar stop to regulate the depth it cuts to.

Plane for planing surfaces of Metal.—This tool has been brought into use within these few years past, to the great improvement of the work of those artists who employ it. These are chiefly the mathematical instrument-makers who are in the constant habit of having to make straight rulers in brass, and prepare work requiring very flat surfaces, such as the limbs of sextants, &c.; but all trades which work in brass and iron, would find their advantage in employing the plane. The stock of this plane is usually made of cast-iron, in form of a hollow box, the bottom, sides, and ends being all cast in one piece; it is usually 12 inches in length, $1\frac{3}{4}$ in height, and $1\frac{1}{2}$ in breadth across the face; the iron is situated at about four inches from the fore end, not inclined, as in other planes, but held in a perpendicular direction, with its lower or cutting edge passing through the mouth, and projecting the least possible quantity beneath the surface of the face, but leaving only so small a space before the edge for a mouth, as will but just admit a piece of thick paper; the iron is held against a brass frame fixed across in the hollow of the box or plane, and containing within it a screw, on which a nut or slider is fitted, to rise and fall when the screw is turned round by a milled head upon the upper end of it; the nut or slider has a projecting pin, which enters into a round hole made through the iron; and in this case, by turning the screw, the iron is raised or depressed, to cause the edge to protrude more or less beyond the face; to support this frame behind, a block of wood is fitted into the hollow of the stock, to fill up all the cavity, and it projects so much above as to form the handle for the plane.

In the front end of the stock a screw is tapped through its thickness, and acts against a piece of wood, which it presses

up against the iron, and thus holds it fast against the brass frame, in the same manner as the wedge of a common plane; this piece of wood is formed forked and hollowed where it applies to the iron, to allow room for the chips to come up from the mouth. The workmen who use this plane call it *stripping*, instead of planing, brass or other metal.

The metal plane is used in the same manner as a carpenter's jack plane, but as the shaving it cuts, or rather scrapes off, must be exceedingly thin, the greatest nicety is necessary in adjusting the projection of the iron beyond the face; and for this reason the screw is essential.

The work is to be supported upon a firm bench, which is best made of cast-iron, and the surface of it made perfectly flat, which is done by grinding the face of the plane against it with emery, till both are true. The front face of the iron is quite flat, and perpendicular to the face; the edge is formed at the bottom of this surface by grinding a bevel from the back at an angle of about 45 degrees; the edge is then made fine by a Turkey stone. The iron must be exceedingly hard and of the very best steel, and then the plane will cut soft steel, bell-metal, or *cast-iron*, as well as brass, to very good purpose. When the work is rough, it is difficult for a man to work the plane, if set coarse for expedition, they therefore use, in such case, an iron which is cut with flutes on the front side, and then the edge will be divided into separate teeth, which scrape and cut away with less resistance than a complete edge. Messrs. Holtzapffel and Deyerlien of Cockspur-street, make these planes for metal of exceedingly hard cast-iron, and very true faces, which do not therefore become scratched or injured by wear. It should have been mentioned before, that joiners, cabinet-makers, &c. in planing thin or valuable woods for veneering, &c. sometimes use fluted irons, having teeth in their edge; and a plane thus mounted is called a *toothed plane*; these irons apply to the stocks of different planes.

PLANE, among *Fowlers*. To plane, is to fly or hover, as a kite or other bird does, without moving its wings.

PLANE, in *Geography*, a town of America, in Stark county, and state of Ohio, containing 527 inhabitants.

PLANE-Tree, in *Botany*. See PLANTANUS.

PLANE-Tree, *Balsard* or *False*. See MAPLE.

PLANE-Tree, in *Planting*, the common name of an elegant tall growing tree of the timber kind, of which there are two species, as the Asiatic, or oriental, and occidental, or American; the first of which rises to a very great height, and in its native soil grows to a prodigious size; the stem is covered with a smooth bark, which falls off annually. The bark of the young branches is of a dark brown, inclining to a purple. The leaves are large and palmated, being deeply cut into five segments: their upper sides are of a deep green, and the under sides pale. The flowers are very minute: they come out at the same time as the leaves, which is in June. This, Mr. Marshall says, is very late, and is, no doubt, a blemish to the beauty of this nevertheless highly ornamental tree. The ancients were very partial to this tree; which is not to be wondered at, when the extensive canopy it forms is considered, the impenetrable shade given by the number and size of the leaves, and consequently the grateful coolness it must afford in a sultry climate. This, as well as the American sort, has been considered as a forest or timber tree; and their wood may rank with that of the sycamore, which bears a considerable resemblance to them, and which, in the north of England, is often improperly called the plane-tree.

With regard to the second sort, or American plane, it grows to a great size; the stem not only swells to an immense thickness but, rising erect, shoots up perfectly straight

straight and cylindrical to an amazing height. The bark is smooth, and, like that of the Asiatic or former fort, falls off annually. The leaves are broad, with long footstalks, and are cut into angles at their edges, but not divided nearly so deep as those of the other kind. The upper side is of a light green, the under side paler. The flowers are small, and come out with the leaves about the same time as those of the Oriental plane. Mr. Marshall thinks that, on the whole, this tree is peculiarly refreshing to the eye, and truly ornamental.

And in addition to these species, there are two varieties of the first fort, as the maple-leaved plane, and the Spanish plane, the first of which differs from the other forts, in having its leaves not so deeply cut as those of the Eastern plane, but much more deeply than those of the occidental. The footstalks of the leaves are much larger than those of either of them, and the upper surface of the leaves is rougher. They might, of course, be taken for different species, if it was not well known that they are produced from the same seeds. The Spanish plane has larger leaves than either of the other forts. They are divided in a similar manner to those of the maple-leaved plane. Some of them are cut into five, and others into three lobes: these are sharply indented on their edges, and are of a light green. It is by some called the middle plane, from its leaves being shaped between those of the first two forts.

The first of these forts may be raised from seeds, where they can be procured; but in other cases recourse must be had to layers. And the ground proper for raising them in, is such as is moist and shady, well dug, and raked until the mould is fine; then in the autumn, soon after the seeds are ripe, they should be scattered over the surface, and be raked in the same manner as turnip seed. In the spring, many of the young plants will appear, but it must not be expected that the general crop will come up until the second year; the spring after which they may be taken out of the seed-bed, and planted in a nursery-ground in rows one yard asunder, and at one foot and a half distance in the rows. Here they should remain, with the usual care of digging between the rows, and keeping them clean, till they are of sufficient size to be planted out in plantations or other places, either as timber or ornamental trees. In the layering method a sufficient number of trees must be planted out for stools, on a spot of earth double dug. After they have stood one year, they should be cut down, in order to make them throw out young wood for layering. The autumn following, these should be laid in the ground, with a little nick at the joint; and by the same time twelve months they will be trees of a yard high, with a good root, ready to be planted out in the nursery, where they may be managed as the seedlings; and as the stools will have shot up fresh young shoots for a second operation, this management may be continued as the planter may think fit.

But the American plane is mostly raised by cuttings; which, if they be taken from strong young wood, and planted early in the autumn, in a moist good mould, will hardly fail of succeeding. They are generally planted thick, and then removed into the nursery-ground, as the layers of the other sort: but if a large piece of ground was ready, Mr. Marshall thinks these might be placed at such a distance as not to approach too close before they were of a sufficient size to be planted out to stand; and this would save the expence and trouble of a removal. The Oriental plane-tree will also grow from cuttings, but not so certainly as this; and whoever has not the convenience of

proper ground for the cuttings, must have recourse to layers, which, indeed, for either fort is the most effectual and certain method of proceeding.

These forts of trees delight in a moist situation, especially the occidental fort. Where the land is inclined to be dry, the others are to be preferred. But in moist places, by the sides of rivulets, ponds, &c. the occidental makes such surprising progress, that it might be ranked among the aquatics. The bright colour of the plane-trees gives variety to groves and masses of wood; in groups and single trees they are singularly elegant; as may be seen in many parks and other places. In such situations and soils they may likewise be planted as timber trees with great advantage, as the wood is useful for a variety of purposes.

And the proper season for planting out this sort of trees is in the early spring, as about March; but they may be set out in the autumn, where the soil is not of too wet a nature, with perfect success, though the other is always to be preferred if possible.

PLANERA, in *Botany*, so named by professor Gmelin of Gottingen, the very incompetent editor of the *Linnaean Systema Naturæ*, at least as far as the vegetable kingdom is concerned. He appears to have designed to commemorate James Planer, who published an Index of the plants about Erfurt, where he was professor of medicine. Gmelin took his ideas of the genus from Walter's *Flora Caroliniana*, 230, it being one of those which that writer had described as new, but which he had declined naming. Michaux has adopted *Planera*, *Fl. Boreal-Amer.* v. 2. 247, as has Mr. Pursh in his *Fl. Amer. Septentr.* v. 1. 115. Both remark its very near affinity to *Ulmus*. Indeed Michaux's description hardly indicates any difference, except the flowers being polygamous, which is of no generic importance whatever. Michaux defines two species; *P. Gmelini*, a native of North America, *Anonymos aquatica* of Walter; and *P. Richardi*, a native of the country near the Caspian sea. This latter has long been known in the gardens of France and England, by the name of the Siberian Elm, or *Ulmus polygama*. *Ulmus nemoralis* of both editions of Hort. Kew. always appeared to us the same thing, but Mr. Pursh has the latter as a native American *Ulmus*, though Michaux has not any species under that name, nor does he give his *Planera Richardi* as an American plant. Pallas has figured the Caspian tree, under the appellation of *Rhamnus carpinifolius*, *Fl. Ross.* v. 1. t. 60, but he had not seen the ripe fruit. Whatever this Caspian plant may be, the *Abelicea cretica* of Pona, *Clus. Hist.* v. 2. 302, is certainly another species of the same genus, as has been shewn by the writer of the present article, in a paper on the subject of that little known plant, printed in *Tr. of the Linn. Soc.* v. 9. 126. Whether the genus in question be distinct from *Ulmus*, appears very doubtful; but if it should so prove, the name of *Planera* must give way to *Abelicea*, as a Greek name, published long since, and of good authority. See *ULMUS*, where possibly we may be able to throw some further light on this subject.

• PLANET, PLANETA, πλανητης, *wanderer*, in opposition to a *star*, which remains fixed, in *Astronomy*, a celestial body revolving round the sun as a centre, and continually changing its position with respect to the other stars.

The planets are usually distinguished into *primary* and *secondary*.

PLANETS, *Primary*, called also simply, and by way of eminence, *planets*, are those which move round the sun as their proper centre. Such are the Georgian, Georgium Sidus or Herschel, Saturn, Jupiter, Vesta, Juno, Pallas, Ceres, Mars, the Earth, Venus, and Mercury.

PLANET.

PLANETS; *Secondary*, are such as move round some primary planet as their respective centre, in the same manner as the primary planets do round the sun. Georgium Sidus, Saturn, Jupiter, and the Earth, are each attended with secondary planets; the Georgian with six, Jupiter with four, and Saturn with seven, called the *satellites* of those planets. The Earth has one secondary planet, called the *Moon*; which see.

The motion of the primary planets is very simple and uniform, as being compounded only of a projectile motion, forward in a right line, which is a tangent to the orbit; and a gravitation towards the sun at the centre. (See GRAVITY.) Besides, as they are at such vast distances from one another, the effects of their mutual gravitation are in a considerable degree, though not altogether, insensible; for the action of Jupiter on Saturn, *e. gr.* is found to be $\frac{1}{100}$ of the action of the sun upon Saturn, by comparing the matter of Jupiter with that of the sun, and the square of the distance of the sun from Saturn, with the square of the distance of Jupiter from Saturn; so that the elliptic orbit of Saturn will be found to be more just, if we suppose its focus not to be in the centre of the sun, but in the centre of gravity of the sun and Jupiter, or rather, in the centre of gravity of the sun, and of all the planets below Saturn. In the same manner, the elliptic orbit of any other planet will be found more accurate, by supposing its focus to be in the centre of gravity of the sun, and of all the planets that are below it. But the matter is far otherwise in respect of the secondary planets; for every one of these, though it chiefly gravitate towards its respective primary one, as towards its centre, yet at equal distances from the sun, it is also attracted towards him with an equally accelerated gravity, as the primary one is toward him; but at a greater distance with less, and at a nearer distance with greater: from which double tendency towards the sun, and towards their own primary planets, the motion of the satellites, or secondary planets, comes to be very much compounded, and affected with many inequalities: as, for instance,

1. The satellite shall be continually accelerated in its motion, from the time of its quadrature with the sun to the next following conjunction or opposition; but contrarywise from the syzygies to the quadratures, it shall be retarded; and therefore it will always move swifter in or near the syzygies, and slower near the quadratures. From whence will follow that,

2. The orbits of these secondary planets will be of a figure more circular in the quadratures than in the syzygies, where the swiftness of the motion will make the figure of the orbit more rectilinear, and therefore the satellite will run farther from its primary planet at the quadratures than at the syzygies; so that the orbit will be a little elliptical, having the primary planet for its centre, and the longer diameter will coincide with the line of the quadratures, and the shorter with that of the syzygies. Which irregularities will arise, if the sun's power of disturbing the motion of the satellite be excluded, and the orbit be concentric with that of the primary planets: for if the orbit be excentric, it may happen that the satellite shall be farther off from the primary one in the syzygies, and so move slower than it does at the quadratures; and when this is the case, that the satellite's orbit is not a circle concentric to the primary orbit, but an ellipsis, in one of whose focuses the primary planet is placed, then the motion of the satellite will be so disturbed by the sun, that, as it proceeds in its orbit, the apfides of the orbit will be moved sometimes in *consequentia*, and sometimes in *antecedentia* (whereas the nodes and

apfides of the primary planets may be considered as at rest.)

3. When the plane of the satellite's orbit is inclined to the plane of the primary orbit, the line of the nodes of the secondary orbit will be moved in *antecedentia*, with an angular motion, and an unequal velocity; for it will recede most swiftly when the nodes are in quadrature to the sun; after which it will move slower; and at the time of the nodes being in the syzygies, it will be perfectly at rest.

4. The inclination also of the plane of the secondary orbit, to the primary one, will be continually varying, and will be greatest when the nodes are in the syzygies with the sun, and less, *ceteris paribus*, when they are in the quadratures; and from the time of the nodes being in the syzygies to the quadratures, it will be always decreasing, and from the time of their being in the quadratures to the syzygies, it will be always increasing; and all these irregularities, whether in any excentric or concentric orbit, will always be something greater, when the satellite is in conjunction with the sun, than when he is in opposition to him. See MOON and SATELLITES.

The primary planets are in number eleven, (including the earth) ten of which are again distinguished into the *superior* and *inferior*.

PLANETS, *Superior*, are those farther from the sun than our earth is. Such are Mars, Vesta, Juno, Pallas, Ceres, Jupiter, Saturn, and the Georgian.

PLANETS, *Inferior*, are those nearer the sun than our earth, and situate between the earth and sun. Such are Venus and Mercury. See the order, position, &c. of the planets, under *Copernican SYSTEM*.

The planets are represented by the same characters as the chemists use to represent their metals by, on account of some supposed analogy between those celestial and subterraneous bodies.

The Georgian is represented by the character ♃, and performs its sidereal revolution in about 84 years.

According to La Place, the first five satellites of this planet may be retained in their orbit by the action of its equator, and the sixth by the action of the interior satellites; and hence he concludes, that this planet revolves about an axis very little inclined to the ecliptic, and that the time of its diurnal rotation cannot be much less than that of Jupiter or Saturn. When the Earth is in its perihelion, and the Georgium Sidus in its aphelion, the latter becomes stationary, when his elongation or distance from the sun is $8^{\circ} 17' 37''$, and his retrogradations continue $151^{\text{d}} 12^{\text{h}}$. When the Earth is in its aphelion, and the Georgium Sidus in its perihelion, it becomes stationary at an elongation of $8^{\circ} 16' 27''$, and the retrogradations continue $149^{\text{d}} 18^{\text{h}}$. The following table contains the most correct elements of the orbit of the Georgium Sidus, and other particulars relating to this planet.

The planet Ceres, first discovered by Piazzi, January 6, 1801, and afterwards by Dr. Olbers of Bremen, Jan. 1, 1807, nearly in the place where it was expected to appear from the calculations of baron Zach, is of a ruddy colour, and seems to be about the size of a star of the eighth magnitude; apparently surrounded by a dense atmosphere, and plainly exhibiting a disc, when examined with a magnifying power of about 200. Its revolution round the sun is performed in four years, seven months, and ten days; at a mean distance of nearly 260 millions of English miles. The eccentricity of its orbit is somewhat greater than that of Mercury, and its inclination to the ecliptic exceeds that of all the old planets. According to Dr. Herschel, its diameter does not exceed 160 miles, whereas Mr. Schroeter makes it 162.4 miles. The following table comprehends all the particulars that are known concerning it.

Tropical revolution, La Lande	4 ^y 7 ^m 10 ^d

See CERES, and *Planetary NUMBERS*.

For an account of the planet Pallas, see PALLAS, and *Planetary NUMBERS*.

Juno, a planet discovered, as we have said under JUNO, in 1804, is of a reddish colour, and free from that nebulousness which surrounds Pallas. Its diameter is less, and its distance greater than those of the other new planets. It is distinguished from all the other planets by the great eccentricity of its orbit; and the effect of this is so extremely sensible, that it passes over that half of its orbit, which is bisected by its perihelion, in half the time that it employs in describing the other half, which is farther from the sun. From the same cause, its greatest distance from the sun is double the least distance, the difference between the two distances being about 127 millions of miles. The following elements were calculated by Burekhardt.

Revolution	5 ^y 182 ^d
According to others (see <i>Planetary NUMBERS</i>) in	1590 ^d 1 35'

See JUNO.

Dr. Olbers, who had distinguished himself by the discovery of two of the new planets, conceived, that these small celestial bodies were merely the fragments of a larger planet, which had been burst asunder by some internal convulsion, and that several more might be discovered between the orbits of Mars and Jupiter. He therefore concluded, that though the orbits of all these fragments might be differently inclined to the ecliptic, yet, as they must have all diverged from the same point, they ought to have two common points of reunion, or two nodes in opposite regions of the heavens, through which all the planetary fragments must sooner or later pass. One of these nodes Dr. Olbers found to be in Virgo, and the other in the Whale, and it was actually in the latter of these regions that Mr. Harding discovered the planet Juno. With the intention therefore of detecting other fragments of the supposed planet, Dr. Olbers examined, thrice every year, all the little stars in the opposite constellations of the Virgin and the Whale, till his labours were crowned with success on the 29th of March, 1807, by the discovery of a new planet in the constellation Virgo, to which he gave the name of Vesta. This planet was observed at Blackheath the 26th of April, 1807, by S. Groombridge, esq., an ingenious and active astronomer; and pursuing his observations with persevering attention and industry, he at length, viz. on the 8th of September, 1808, observed the ecliptic opposition of this planet at 7^h 30' in longitude 11° 15' 54' 26".

The planet Vesta is of the fifth or sixth magnitude, and may be seen in a clear evening by the naked eye. Its light is more intense, pure, and white than any of the other three. It is not surrounded with any nebulousness, and has no visible disc. (Phil. Transf. 1807, part ii. p. 265. 260.) The orbit of Vesta cuts the orbit of Pallas, but not in the same place where it is cut by that of Ceres. According to the observations of Schroeter, the apparent diameter of Vesta is only 0.488 of a second, one half of what he found to be the apparent diameter of the fourth satellite of Saturn; and yet it is very remarkable, that its light is so intense, that Mr. Schroeter saw it several times with his naked eye. Phil. Transf. 1807, part ii. p. 245.
